WE heartily welcome a new and extended edition of this interesting and useful work, the former edition of which has been for some time out of print. A supplementary volume, published in 1862, which had become necessary in consequence of the frequent introduction of many new species, and endless varieties, causing what the author in his preface called a Babylonian confusion of names, which urgently required such rectification as was practicable, is also out of print. That supplement, combined with an accurate account of still more recent introductions, is embodied in the present solid and practically useful volume, which is rendered all the more valuable by Mr. Bohn's index of "popular" names. The addenda bring the contents of this volume up to the present hour, so to speak. Among new Conifers a variety of Norfolk Island Pine (*Araucaria excelsa speciosissima*) is described. Its distinguishing characteristics are greater hardiness than that of the ordinary Norfolk Island Pine, and the remarkable length of the leaves, in which particular, however, it closely resembles *A. Cunninghamii*. Then there is *Cryptomeria japonica*, considered to be the original form of the Japanese Cedar, found in the north of Japan, and differing from the one originally introduced by Mr. Fortune in having a more compact habit of growth, and not in being subject to turn so brown in the winter. Also a variety of Gowan's Cypress, called *Cupressus Goveniana glaucescens*, raised by M. Sahul, of Montpellier. This is of a light and almost blue glaucescent character, and by its use fine contrasts of colour may be produced in plantations where Conifers play a conspicuous part, as the hoary-blue tint of its foliage will prove of great value in producing masses of light-toned foliage. The effect of the contrast, just suggested, may be varied by a beautiful new variety of *Cupressus Lawsoniana* (Lawson's Blue Cypress); a novelty like the last-named, raised on the Continent. It has the advantage of always retaining its greyish-blue tint, shaded with deeper grey, summer and winter. Another interesting variety of the Lawson Cypress, as stated in Mr. Gordon's addenda, has been raised by Mr. Barron, of the Elvaston Nursery. In this the young shoots, and also the young wood, are of a bright canary-yellow, a colour not impaired either by the sun's rays in summer or the frosts in winter. A new Juniper is also described, which appears to have great attractions. It is a sport from the male form of the original plant, and has all the more prominent portions of the foliage suffused with a rich golden colour, which retains its bright auriferous tint both in winter and summer. A new golden Yew is also described, in which the younger branches are of a bright orange colour. In winter it is by far the most brilliant of any of the golden varieties. By way of contrast with these light grey and golden Conifers, an unusually dark toned *Arborvitæ* is described under the name of *Thuja gigantea atrovirens*; for such contrasts as those suggested this will be most valuable. It will thus be seen that Mr. Gordon's volume contains very interesting information in reference to the latest novelties in the way of Conifers, while its main bulk is devoted to complete descriptions of all the hitherto known species of that interesting tribe, many of which have not been utilised to anything like the extent which their merits deserve. Among Spruce Firs alone, many will be found described which have not as yet had a chance of displaying their picturesque and valuable characteristics in this country. Take, for instance, the Alcock Spruce (*Abies Alcocquiana*), a kind named in compliment to Sir Rutherford Alcock, the British Minister at the Court of Yeddo, who discovered it on the Sacred Mountain, Fusi-Yama, on the island of Nippon, where it formed noble trees from 90 to 100 feet high, at an elevation of 7,000 feet above the level of the sea. This fine tree was introduced by Messrs. Veitch in 1861. There is also Engelmann's Spruce, which attains as great a height on the mountains above the Colorado River, and also on the highlands of Santa Fé, in New Mexico, as the Alcock Spruce. In strong contrast to these giants, again there is the Pigmy Spruce (*A. excelsa pygmæa*), the dwarfest of all Firs, scarcely a foot high, which is not so often seen as it should be. Altogether, there are twenty distinct kinds of Spruce Fir fully described, seventeen Cypresses, besides a number of distinct and beautiful varieties; and the same may be said of the Junipers, the Larches, the Pines (of which ninety-two kinds are enumerated), the Silver Firs (*Picea*), and every other kind of Conifer—among

which planters will find abundant variety. Valuable and interesting as Mr. Gordon's volume must be admitted to be, it contains, however, a few blemishes, which, though comparatively unimportant, it will be well to amend when a new edition is called for. As an example of the kind of shortcoming alluded to, we may instance the description of the well-known Stone Pine (*Pinus Pinea*), the account of which, gathered from various sources of information, is somewhat carelessly put together. The general aspect of the Stone Pine, which forms one of the great charms of Italian landscape is, as is well known, that of a towering, branchless trunk, attaining the height of from 50 to 70 feet, surmounted by a spreading canopy of dark foliage, a character which our landscape painters, from the time of Turner, have turned to glorious account in their Italian compositions of both mountain and villa scenery. How are these characteristics to be made to accord with the following disjointed account:—"A low growing tree, with a round bushy appearance, from 15 to 20 feet high. . . . It is cultivated throughout the whole of Italy. . . . It forms a very ornamental small tree, with a rounded head, so celebrated for producing a fine effect in Italian villas." The last remark shows that there is no mistake as to the kind of Pine intended to be described, which is further corroborated by the observation, in another part of the description, that its seeds, or nuts, form an extensive article of commerce in Italy and the South of France. In another place, the full grown height is described as 50 or 60 feet. These inconsistencies and contradictions may be easily amended; as well as such slips of the pen as that which describes the Stone Pine as attaining a height of 2,000 feet, when the author meant to say that it thrives well at that elevation. These slight imperfections, however, in no way impair the practical usefulness of the book, nor the vast amount of valuable information which it contains on the subject of cone-bearing trees. The value of Mr. Bohn's index is very great, and, written by him in his eightieth year, adds another to the many evidences of his knowledge and industry. The following is an example of the way in which it is arranged, except that, for the sake of space, the names are run together, instead of being in the usual form:—*Abeto. Italian. Picea pectinata. Common Silver Fir.—Abyssinian Juniper. Abyssinia. Juniperus procera.—Acuminate Swan River Cypress. Actinostrobus Acuminatum.—Adventure-Bay Pine. Tasmania. Phyllocladus rhomboidalis.—African or Atlantic Cedar. Atlas range N. Africa. Cedrus Atlantica.—African Cypress. Madagascar, etc. Widdringtonia.—Agath-Tanne. German. Dammara Orientalis. Amboyna Pine.—Agrion Elaton. (Wild Fir.) Cephalonia. Picea Apollinis. Mount Enos Fir.—Aka-Matsu, (Red Pine.) Japan. Pinus densiflora. Dense-flowered Japan Pine.—Ak-cherschal. Tartary. Picea Pichta. Siberian Silver Fir.—Alcock Spruce. Japan. Abies Alcocquiana.—Aleppo or Jerusalem Pine. Sicily and Greece. Pinus Halepensis.—Alerce. Barbary. Callitris quadrivalvis. Jointed Arbor-vitæ.—Alerce. Spanish. Pinus Larix. The Larch.—Alerce. Chili and the Cordilleras. Libocedrus tetragona. Tetragonal Arbor-vitæ. H.*

Pitcher Plants at Drumlanrig.—In a description of the *Nepenthes*, at Drumlanrig, by Mr. Muir, a short time ago, he mentions dozens of Pitchers of *N. distillatoria* that would hold a pint. Now, if this is really a fact, it would be interesting to many who, like myself, take an interest in these plants, to learn something of the treatment under which such results were produced. It certainly is not the rustic baskets, of which Mr. Muir speaks, that has caused them to attain such a size; for, tasteful as is the appearance of these, the plants do not acquire in them that strength and vigour which they do in pots. Pitcher plants are spare-rooting subjects, and the points of the feeding roots protruding to the outside of the baskets perish; this I have long ago proved by experience. I have been fairly successful in the cultivation of *Nepenthes*, as many who have seen my plants can testify. I have also seen most of the best grown collections in the country, but, with two exceptions, I never yet saw Pitchers of any variety, not even of the largest species, *N. sanguinea* and *N. Rafflesiana*, that would hold a pint. I have seen numbers that were said to do so, but which, when they came to be tried, generally held much nearer half-a-pint than a whole one. The two Pitchers, of which I speak, I now have in a dried state, and, when cut from the plant, one held an imperial pint and the other a small wine-glassful over a pint. But these were not grown in a way to fairly illustrate the best cultivation. I had a remarkably vigorous plant in a 9 or 10-inch pot, with two extraordinarily strong shoots, some 3 feet long, for a purpose wholly apart from any intention of producing large Pitchers. In the middle of the growing season I nipped out the points of the shoots just above a couple of strong leaves in course of formation, and at the same time all the eyes were cut out from the top of the shoots down to within a few inches of the base; this, therefore, threw all the strength of the plant into the two top leaves, and the two Pitchers referred to were the result.—T. BAINES.

* "The Pinetum: being a Synopsis of all the Coniferous plants at present known, &c." By George Gordon, A.L.S. H. G. Bohn, Henrietta Street, Covent Garden. 1875.

NOTES OF THE WEEK.

— THE rare and beautiful *Tulipa Greigi* was shown in good condition at South Kensington on the 17th inst., by the Colchester Seed and Bulb Company. It has thick waxy foliage of a glaucous hue, blotched with purple, and the flowers are golden-yellow without, bright crimson within, and have a large feathered blotch of deep velvety-black inside, near the base of each segment. It is a native of the Caucasian Mountains, and is well worth the attention of all lovers of hardy early-flowering showy bulbous plants.

— THE new *Phalenopsis Veitchii* is now in flower in the Royal Exotic Nursery, at Chelsea. It is supposed to be a natural cross between *P. rosea* and *P. Schilleriana*, having the speckled foliage of the last-named plant, and flowers intermediate between the two species, both in point of size and colour. Two fine specimens of *Dendrobium Wardianum* are also in flower, in the same establishment, and there is a very good display of forced white Lilac, Tea Roses, and home-grown Lily of the Valley.

— AT the last meeting of the Royal Horticultural Society, at South Kensington, Mr. E. Bennett, gardener of the Marquis of Salisbury, at Hatfield, showed a cut spike of the well-known *Hedychium Gardnerianum*, bearing fruit, the crimson covering of which, interspersed among the brilliant orange-tinted ruptured capsules, had a pretty effect. In order to secure this the old flower-stems should be allowed to remain and bear seeds, instead of being cut down, as they usually are, as soon as the beauty of the blossoms is over.

— DR. R. A. PRYOR intends publishing a new "Flora" of Hertfordshire, and to enable him to make it as complete as possible, he has issued a circular containing lists of plants respecting which further information is needed. Critical species will be thoroughly studied out. Webb and Coleman's "Flora Hertfordiensis" (1849), supplements to which appeared in 1851 and 1859, is a good work, and the only "Flora" of the county hitherto published; but so much has been done in critical botany of late that it is, in this respect, out of date.

— WE learn that the export of *Cinchona* bark from the Neilgherry hills, on the part of the Government, during 1872-73, the first regular year of export, amounted to over 20,000 lbs., which realised £4,000 in the London market. It is anticipated that the returns of the exports for the past year, 1873-74, would show a similar quantity, and that the trade in future years will rapidly increase. Bark from private *Cinchona* plantations in the East Indies and Ceylon appears regularly in the London market, fetching from 10d. to 4s. per lb. "Very good average prices," it is said, "as compared with those obtained by the South American barks."

— THE International Exhibition of Fruit and Flowers, to be held at Edinburgh on the 15th and 16th of September next, is, we are glad to learn, likely to prove one of the most successful of the great autumn fruit shows held of late years. The Committee have met with liberal support from the residents of the city and its vicinity, and the schedule of prizes has been issued. The prizes are of the most liberal character, as, for example, a first prize of £10 is offered for eight varieties of Grapes, one bunch of each; a first prize of £16 for collections of sixteen dishes of fruit; and one of £10 for twelve dishes. Pine-apples, Pears, Apples, and other fruits also receive liberal encouragement. Amongst the special prizes offered, we observe that Messrs. Sutton and Sons offer prizes for Melons and Cucumbers; Messrs. Boyd, horticultural builders, of Paisley, a silver cup for a stand of Grapes consisting of six varieties; Mr. Monro a series of prizes for Cucumbers; and Mr. Horsburgh a portfolio of photographic views of Abbotsford, of the value of £5 5s., for the best Palm. For particulars of the prizes, conditions of competition, and other information, we must refer our readers to the schedule.

— BOXWOOD, which is almost exclusively used for wood engraving, is becoming more and more scarce. The largest wood comes from the countries bordering on the Black Sea. The quantity exported from Poti direct to England during 1873 amounted to 2,897 tons, of the value of £20,621; besides this, from 5,000 to 7,000 tons of the finest quality, brought from Southern Russia, annually pass through Constantinople. An inferior and smaller kind of wood supplied from the neighbourhood of Samsoun is also shipped at Constantinople to the extent of about 1,500 tons annually. With regard to the Boxwood forests of Turkey, the British Consul at Constantinople reports that they are nearly exhausted, and that very little really good wood can be obtained from them. In Russia, however, where some little Government care has been bestowed upon forestry, a considerable quantity of choice wood still exists; but even there it can only be obtained at an ever-increasing cost, as the forests near the sea have been denuded of their best trees. The trade is now entirely in English hands, although formerly Greek merchants exclusively exported the wood. In the province of Trebizonde the

wood is generally of an inferior quality; nevertheless, from 25,000 to 30,000 cwts. are annually shipped, chiefly to the United Kingdom.

— A CLUB, to be called the Lindley Club, was inaugurated the other day, and is intended to serve as a bond of union among horticulturists, both for social purposes and for the promotion of their respective pursuits. The subscription is 10s. per annum.

— It is understood that the endeavours which have for some time past been made to procure a public park for Wolverhampton are becoming more satisfactory, and that it is probable that the Old Merridale Estate, consisting of 70 acres of land, will be transferred to the Corporation before long. Wolverhampton is certainly much in need of some place of recreation free from the smoke of the town.

— THE botanical productions of the Queensland North-East Coast Expedition are important from an economic point of view. Extensive districts, the soils of which cannot be surpassed in quality, and which support a truly tropical vegetation, including the Bamboo, Tara, and Banana, have been discovered. In some places, too, the timber trees were very fine, particularly of *Calophyllum*, *Inophyllum*, *Eugenia grandis*, *Terminalia melanocarpa*, *Hernandia ovigera*, *Cardwellia*, *Cedrela*, *Alstonia*, *Castanospermum*, and others.

— A NEW Hybrid Perpetual Rose, named *Hippolyte Jamin*, was exhibited, and received a first-class certificate, at the meeting of the Royal Horticultural Society, on the 17th inst., by Mr. Bennett, of Stapleford. It appears to be robust in habit, and has fine waxy foliage. The flower is well filled with stout smooth petals, the colour of which is a rich rosy-purple. The value of a Rose can scarcely be judged from forced blooms, but this one seems likely to become a favourite.

— THE "Kölnische Zeitung" reports that besides *Phylloxera* and the Colorado Beetle a third noxious insect has come over to Europe from America; it is the so-called Blood Louse, which causes much damage to Apple trees. As a practical remedy against this unwelcome guest, it is recommended to paint the young tree with naphtha and lime-water. With larger trees, of course, this is impossible; but it is said that if during winter a thin lime paste is placed in a circle round the tree where it comes out of the ground, the ova of the Blood Louse are then completely destroyed.

— It is proposed to plant extensively the Red Cedar in Bavaria. The superiority of the wood of this tree (*Juniperus virginiana*) over all other kinds of Cedar is well known, and the demand for the wood in Bavaria, where immense quantities of lead-pencils are made, has induced some manufacturers to take up the question of the acclimatisation of the tree in that country. Seeds have been sown in the Royal Forest, and about 5,000 young plants have been grown on one private estate: the cultivation of the tree is also being attempted in other parts of Germany.

— MESSRS VEITCH & SONS have just now an unusually fine display of bulbous and other spring-flowering plants in their nursery in the King's Road. Among Hyacinths are many new and distinct varieties, foremost among which may be named Gladstone, a fine single blue, in the way of De Candolle, but clear bluish-lilac; Masterpiece, a deep rich purplish-plum, excellent both in colour and spike; Prince Talleyrand, clear porcelain-blue, the bells being individually fine; and Negro, a dark variety in the way of Masterpiece, but having a much closer spike. The best single red is undoubtedly Duchess of Edinburgh, a bright pink kind, with a deeper stripe of the same colour; Baron Beust, too, is a fine single blue, something like Grand Maître, but of a much clearer tint. Disraeli, a compact single blue, is also good, and Princess of Wales is likewise a good semi-double bright rosy variety; and Oriental Beauty, a clear single buff kind, is quite distinct in tint from all other yellow varieties—to which it is a useful addition.

— EVERY week brings us another prescription, guaranteed to be infallible, to destroy the *Phylloxera*. How imperfect is the best of them the Société des Agriculteurs de France has lately shown by drawing up a petition to the Assembly, begging it to take this most important subject into consideration. There is but one mode of destruction yet suggested which really seems to answer its purpose—submerging the Vineyards for a month at least. The society declares that one-third of the French crop, reaching a yearly value of £20,000,000, is now actually endangered. In five years more, unless something be done, one half the crop will be in peril, and twenty years, at most, will ruin the wine interest of France. The spread of the *Phylloxera* is terribly rapid. There is now before the society a scheme of M. Aristide Dumont, who proposes to dig a canal from the Rhône, by which nearly 200,000 acres of Vineyard may be flooded every winter, and similar measures will become necessary all over France unless the chemists can devise some means of destruction. This fact shows how great a danger threatens—nothing less is at stake than the most important industry of France.

THE FLOWER GARDEN.

THE TUFTED SOAPWORT.

(SAPONARIA CÆSPITOSA.)

LARGE numbers of Alpine plants, remarkable for their graceful tufted appearance, and for their numerous flowers, which are usually of the most brilliant and varied colours, would be used much more commonly than they are for the embellishment of our gardens if their culture did not so frequently offer such apparent difficulties. Nevertheless, attempts commenced in an intelligent manner, and followed up with perseverance, have proved satisfactory in the case of many of these plants, and amongst them must be classed the *Saponaria cæspitosa*, of which the annexed is an illustration of its natural size. How is it possible (says the "Revue Horticole") to account for the difficulty experienced in acclimatising upon lowlands these Alpine plants? No doubt the peculiar character of the soil has something to do with it; but we nevertheless believe that the entirely exceptional climatic conditions to which such mountain plants find themselves subjected, are the principal cause of their delicate constitution, which so often militates against their successful culture in gardens. The reason that plants of elevated regions succumb so often, is, no doubt, principally owing to the sudden changes of temperature, and to the colds of winter. In their natural habitats they are very differently circumstanced, being wintered under snow, and thus enjoy an equable temperature which, thanks to this covering, never falls below zero. When the snow melts, the Alpine plants emerge from their hiding places, and no longer dread the rigours of a winter which, short as it is, would be sufficient to kill them. This difference of climatic conditions appears to us to give a sufficient clue to the difficulty attending their cultivation in gardens. The *Saponaria cæspitosa*, however, succeeds well in most places. It comes originally from the higher regions of the central and eastern Pyrenees, where it flowers in the month of August; but in the lowlands its beautiful rose-coloured blossoms are developed in the end of June. Lapeyrouse, in the "Flora of the Pyrenees," gave it the name of *Saponaria elegans*. It is perennial, and forms rosettes of linear leaves, which are somewhat thick, glabrous, and of a beautiful green colour. The flowers, which form a thick cluster, are supported on short stout stems. This graceful little plant is very valuable for planting on rock-work; a sandy soil suits it best, and it will pass the winter perfectly in the open air, without any particular care being bestowed on it.

The Tufted Soapwort.

PRUNING ROSES.

No operation in gardening has undergone so many changes of pruning Roses; and, for this, among other reasons—~~that the roses~~ themselves are very much changed. When we had few or none but Gallica, Moss, and Summer Roses, they were pruned like Gooseberries, soon after the fall of the leaf; and this answered very well, for these summer-flowering kinds were perfectly hardy and late in starting into growth, and they ran little or no risk of having their flowers blackened by late frosts. But attempts to apply the same sort of pruning to all Roses, and also to prune all at the same time signally failed. Take the case of the Banksian Rose; this, for many years after its introduction, was reputed to be a shy bloomer, and in not a few gardens it bears the same reputation still; simply because it was and often is pruned close, along with other Roses in November. Thus nearly the whole of the flowers are cut clean off. Prune the Banksian Rose early in July as soon as it is out of flower, and in May and June following it will reward you with wreaths of miniature Roses. Hence, we may infer that the different families of Roses, such as Teas, Noisettes, Bourbons, Perpetuals, Ayrshire, Boursault, or other kinds, require different modes and times of pruning—and they do. It is therefore impossible, even were it desirable, to lay down stringent rules concerning either the time or the mode of pruning. Prune, as a rule, however, weak Roses earliest and most severely, and strong Roses least and latest. The facts on which this practice is based are as follows:—The strength that would otherwise have gone to nourish a dozen or a score of flower-buds or shoots is concentrated by severe pruning into one or two, and hence their increased vigour. Consequently, if we want to weaken or moderate growth leave it unpruned or slightly cut back; while by leaving a weakly Rose unpruned, it becomes weaker still. Cut it back to a single bud, and its entire strength is centred in that bud, and, if anything will restore it to vigour, that will.

Best Time for Pruning.

The best time to prune weakly-growing Roses is as soon as the leaf falls. All through the winter the buds left are nourished, and filled fuller by the slow motions of the fluids, which are never at rest unless when frozen. This enables the buds to break with greater vigour in the spring; while, on the contrary, one of the surest recipes for moderating strength of growth, is to leave all the shoots at their full length till February, March, or even April, and then cut them back to weakly dormant buds, thin, and well-nigh empty at the base of the shoots. Thus, by late pruning there is a direct and indirect loss of vital force. The whole of the most fully nourished buds are cut clean away, which is a loss; but the buds left are crippled for lack of food, and are sure to be the weakest and worst on the shoot. It is therefore clear that a repetition of late pruning must lower the vitality and lessen the growth of the most vigorous plants. Most people have vague notions that Roses must be cut back to furnish a succession of

flowering shoots, and to prevent them from becoming bare at bottom. No doubt there are two primary purposes served by pruning; and they are best served by early or autumnal pruning. But other considerations oftener determine the time and extent of pruning than the mere furnishing of the bases of Rose trees and bushes with wood. Modern Rose-growers prune for flowers—flowers of first quality and in long succession. The season of Roses in the open air has been extended from May to November, and the wise pruner takes all this into account, and prunes from November to May accordingly, and then again in June, July, and August. Thus, to have Roses seven or eight months in the open air, he must prune nearly ten months. These three last named months, are, however, for summer pruning only. Now, while from the beginning of November to July is named as the season for winter pruning, that in April and May may be said to be suited to the China, Tea, or other tender Roses in the open air that have been partially protected. Except in abnormal cases, for special purposes, the great family of Hybrid Perpetuals should be pruned not later than February or March, but weak growers among them (if any) should be pruned in December or January. This, however, must be taken with some allowance as to habit of growth; for some of these Roses grow much earlier than others, and if such are pruned too early, the early Roses will assuredly be cut off by late May frosts.

Pruning for Safety from Frost.

But we must prune for safety as well as for continuity of bloom, the moderating of strength, and the furnishing of wood; and, no doubt, this last object has been the most important of all in altering the season of Rose-pruning. With such widely differing classes of plants to deal with, had we gone on pruning all at the same time, fully half our Roses would have been ruined by frosts that now linger in our gardens all through May, seeking what tender buds, shoots, or plants they may blacken or destroy. Almost each variety of the Rose, too, has some special peculiarity, and may need for its highest development a particular and special mode of pruning. Maréchal Niel, for instance, likes to ramble at its own sweet will, and thus shower down its golden treasures far and wide. The Gloire de Dijon can ramble also, and do well when comparatively unrestricted; but it likewise bears close pruning well. By pruning the Tea Roses as soon as each cluster of flowers on a shoot fades, we restore to them the greatest merit of the old pink China, by converting most of them into monthlies. Again, if such a short-stemmed Rose as the Baroness Rothschild, strong and stout as its stumpy shoot is, be not cut in severely, the Roses will hardly clear the leaves, but sit and rest among them. And so on and on of the endless peculiarities of Roses. Therefore, the greatest secret of successful Rose-pruning has yet to be told. It consists in putting practical knowledge into every cut. Only thus can each Rose be pruned to the best advantage, and so as to develop its fullest measure of beauty. D. T. FISH.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rose Isabella Sprunt.—In Mr. Philip Ladds' extensive Rose-forcing houses at Bexley Heath, this Rose has been proved the freest bloomer of the many Tea Roses forced there. In other respects it is an admirable Rose for those who wish to cut blooms in winter and spring.—R.

Water Convolvulus.—Probably this name is at times applied to the hardy Water Lily (*Nymphaea alba*). The term Lily is so commonly applied to the field Convolvulus, that, by a common transposition, the term Convolvulus might be at times applied to the Water Lily.—A. D.

Localities for Alpine Plants.—As I intend to spend a month in Switzerland this summer, can you inform me what are the best localities for getting a good selection of Alpine plants?—G. W. B. [Any of the mountainous parts are certain to afford a good collection of Alpine plants, though, no doubt, some cantons are richer than others. The Engadine and the Canton of Tessin are particularly favoured in this way.]

Hardiness of the White Lapageria.—At Gunnersbury Park, near London, the hardiness of *Lapageria rosea alba* has been put to a severe test during the present winter, a vigorous shoot from a plant growing along the roof of a small span-roofed house having thrust itself through an opening in the wood-work. Though on an open north aspect, the shoot continues as fresh and healthy as those inside the house.—"Florist."

Climbing Plants for a Verandah.—I have a verandah about 50 feet long, open in front, but roofed with opaque glass. I wish to cover the back wall with about a dozen climbing plants. Will you, therefore, name ten or twelve plants suitable for that purpose? The aspect is south-east.—W. N. A. [Try *Jasminum nudiflorum*, *Passiflora cœrulea*, Maréchal Niel Rose, various Clematises and Honeysuckles (the trumpet-flowered kind being as good as any), *Cotoneaster microphylla*, *Chimonanthus grandiflorus*, *Lapagerias* (both red and white), and some of the finer varieties of Ivy, both green and variegated.—PHILIP FROST, *Dropmore*.]

Selaginella denticulata as an Edging.—Do any of your readers use this for carpet bedding? It would make a pretty edging to some of our dark-foliaged plants, such as *Iresine*, Beet, and others, and it would also make a nice carpet running amongst such plants. I planted two plants of it in the open air last spring, when they not only grew well, but have withstood 10° of frost this winter, and, although they have been twice covered with snow since, at present they are quite healthy, and are still growing. I intend planting a few dozens of this *Selaginella* this year.—JOHN CLARKE, *Cork*. [It would form a very useful mossy carpet-plant in the flower garden.]

THE LIBRARY.

FOREIGN HORTICULTURAL PUBLICATIONS.

THE "Gartenflora," for January, contains a figure of *Oxalis Ortgiesii*, a species of the corniculata section, with a stem from a foot to a foot-and-a-half high, curiously formed truncate leaflets, and yellow flowers, produced in great profusion all through the summer in the open ground at Zurich. It was collected by Roezl in the Andes of Peru. The second figure is of the dark deep-coloured variety of *Sedum spurium*, called *splendens*. This is one of the most ornamental of the trailing Sedums, and very desirable on account of its long flowering season. It is a native of the Caucasus. The third is an uncoloured figure of the *Rheum palmatum* var. *tanguticum*, which M. Maximowicz declares to be the true source of the genuine Turkey Rhubarb of commerce. It was obtained from the alpine woods near Lake Koko-nor, in north-west China, the district in which Rhubarb cultivation for the Russian trade was formerly carried on. It is not denied that *Rheum officinale*, recently figured in the "Botanical Magazine," yields a superior kind of Rhubarb, but it is argued that the plant in question is the one that furnished the drug known to the early physicians. Messrs. Flückiger and Hanbury are accused of having been too precipitate in accepting *R. officinale* as the true plant. In reality, of course, this question is of more historical interest than present importance, for the quality of the drug grown and prepared in this country is said to be little, if at all, inferior to the best imported. Both *R. officinale* and *R. palmatum* are ornamental plants, the latter especially, having elegant deeply-divided leaves. The "Hamburger Garten und Blumen Zeitung," is one of the best of the German horticultural journals which find their way to this country. It is not embellished with coloured plates, but illustrative wood-cuts are occasionally given. A large portion of the first number for this year is devoted to cultural articles, and the commencement of an enumeration of the Palms of Herrenhausen, probably the finest collection in existence. In a note on the "Roffia Grass" of gardeners, a Mr. Rothe invites us to believe in a startling "discovery" of his, that this tying material is a species of sea-weed; but this is asking too much. The February number is very good indeed on the whole, but it opens with an unfortunate article on "The Genuine Rhubarb," professedly based upon communications from Dr. Regel, the editor of the "Gartenflora." How it came about, it is impossible for us to say, but the writer speaks of *Rheum officinale* and *R. palmatum tanguticum* as the same plant! Yet they are as distinct from each other as any two species we know; and, as mentioned above, they are distinguished in the "Gartenflora." We could not believe that the editor of the latter journal was playing false with his *confrère*, and truly, we find on reading over the paragraphs given in inverted commas, that such was not the case. The writer adds, "we may probably refer to this plant again," which will, doubtless, be considered necessary; for, half-a-dozen lines further on, we are informed that "with the exception, perhaps, of the 'Californian' (N. Indian) *Rheum nobile*, this is the most beautiful species of the genus." This is followed by an interesting article on fruit-growing, especially the management of cordons. The object is to point out the advantages of the cordon system, and at the same time to give some instructions how to carry it out successfully. In Germany, it appears, this system, so universal in France and Belgium, is as slow in making its way as in this country. The writer points out its advantages, and how very easily one may learn to practise this agreeable and profitable branch of fruit-growing. Woodcuts are given in illustration, and a list of Apples and Pears suitable for this treatment. These lists being short, we may re-produce them for comparison with the sorts usually grown in this country:—Pears: *Beurré Clairgeau*, *Beurré Diel*, *Brown Autumn Beurré*, *Grey Autumn Beurré*, *Napoléon*, *Beurré Bachelier*, *Hardenpont's Winter Beurré*, *Beurré Liegel*, *Abbé de Beaumont*, *Soldat Laboureur*, *Ah! Mon Dieu!* and *Archduke Charles*. Apples: *White Winter Calville*, *Red ditto*, *Gravenstein*, *Winter Golden Pearmain*, *Herefordshire Pearmain*, *Blenheim Golden Reinette*, *Royal Short-stalk*, *Golden Pippin*, and *Ribston Pippin*; amongst *Reinettes* the *Canada*, *Ananas*, *Bauman's*, *Brittany*, *Orleans*, and *Breda*. The further contents are:—"Some Notes on my last Trip to New Grenada," by G. Wallis, which includes a list of some of the writer's principal discoveries; "Palms of the Royal Gardens of Herrenhausen" (continuation), bringing the enumeration down to *Calyptrigyne*; "Cultivated Species and Varieties of Holly"; "On the Culture of Gladioli," by F. Gloede; "Newly-introduced Plants"; "The Kostritz Dahlias," by Dr. Krause (a patriotic contribution in favour of German varieties, which are said to be equal in colour, superior in shape, if not in size, to the best English. Christian Deegen is the name of the raiser who has been so successful. The German varieties exhibit, it is affirmed, an improvement in habit, and especially in their earlier flowering season

(many of them being in full bloom in June); "New Echeverias, Descriptions of the Hybrids raised by Deleuil;" &c.

The Kitchen Garden.*

Of late years the Belgian Government has given much encouragement to all classes of cultivators, and corresponding progress has been noticeable in some branches of horticulture. The complaint is, however, heard amongst Belgians themselves, that kitchen gardening, notwithstanding its lucrative character, has not advanced in the same proportion as other departments; let us therefore hope that the second edition of the "Jardin Potager," which is published in Belgium, and is the work of M. H. Spruyt, may be the means of remedying this defect. The book is carefully and concisely written, and the directions and descriptions, without being too diffuse, are sufficiently ample to be intelligible. It deserves a wide circulation, for, within its 612 pages, an immense mass of useful information is to be gained.

The "Revue de l'Horticulture Belge," the first number of which appeared this month, is another valuable addition to the monthly horticultural journals of Belgium. In addition to two excellent coloured plates—one of the beautiful Rose, Gloire de Ducher, the other, a remarkably good representation of the true and false Colorado beetles and their larvæ—the number contains several neatly-executed wood-cuts, one of which, illustrative of an article upon

Moveable Flower-beds,

we consider of sufficient importance to transfer, together with the description, to our columns. The idea of forming these moveable flower-beds by means of compartments or pans made either of earthenware or zinc was realised the year before last for the first time by Mr. Schliessman, of Castel, at the horticultural exhibition at Darmstadt. The invention is a peculiarly ingenious one, the value of which will doubtless be fully recognised before long. The accompanying cut shows only three sorts of pan, each to contain a

Moveable Flower-beds

distinct kind of plant. No. 1, of a square form; No. 2, having one of its sides a little rounded; No. 3, of a triangular form. It is expected that the most diverse combinations may be effected by means of this invention. Without taking into consideration horticultural exhibitions, which are likely to render the use of these beds very common, there is a crowd of circumstances under which very surprising effects may be almost instantly produced through their agency. This reminds one of those "Flower Islets," originated by the Prince de Ligne, the grandfather of the present President of the Belgian Senate. These were formed by tufts carrying a depth of earth sufficient for the purpose, and which were thus embellished with magnificent flowers. Every day a change was made, and some fresh floral combination sprang as it were from the water under the windows of the Château de Belœil.

The Sunflower as a Preventive of Fevers.—We continue to see favourable mention made of the virtues of Sunflowers as preventives of bilious fever, chills, fever, &c. A correspondent of the "Soil of the South," writing from a place in Alabama, which he says was peculiarly subject to fevers, gives the results of his experience on the premises, and in not a single instance where he planted Sunflowers around his negro cabins did their inmates suffer from fevers; while his wife, two children, and two house-servants all had fevers, he not having planted any of the Sunflowers around his own dwelling, which, in his opinion, accounted for the difference in the results. We trust that, next spring, New Orleans may be surrounded by a cordon of Sunflowers, that they may be scattered through every garden, and cover every vacant lot in the city.

THE INDOOR GARDEN.

FORCING THE GOLDEN-RAYED LILY.

(LILIUM AURATUM.)

WHEN it is considered that this Lily is one of the best of the genus for conservatory decoration, to get it to flower in perfection is worth a little trouble. The way by which I get it to produce strong flower-stems and plenty of fine blossoms is as follows:—I set apart a space in the propagating-bed, in size according to the number of bulbs I want to force. I then, with pieces of board, form a little square enclosure for each bulb; why I do this is to keep the roots of each separate, and to render them less likely to get broken when raised. For an ordinary-sized bulb I allow from 2½ to 3 square inches, which I fill up with damp Cocoa-nut fibre, in which I insert the bulbs. For these the bottom-heat should not be more than 55°, as a greater amount of heat must cause them to throw up weak stems. They should not be kept very wet, nor more than three-quarters of an inch below the surface. In about a fortnight or so they will have made plenty of roots, and will be beginning to throw up flower-stems, the bases of which, when about three-quarters of an inch in height, are bared a little, so as to let in air and light. When the stems have reached a foot in height, I lift the bulbs and pot them in three parts of good fibrous loam, and one part well rotted leaf mould and silver sand in a somewhat warm condition. The heat in the soil is obtained by burying in it some red-hot bricks, which warm it speedily, and that which gets burnt I place on the crocks as an impediment to the ingress of worms. The raising of the bulbs for potting is an operation which must be done with care. I place the left hand under the bulb, and with the right one gently raise the roots all around. I then pot them in 32-sized pots, after which I water them with tepid water and plunge them half the depth of the pots in the same house till they have become established. I then raise them on to the top of the bed, where they stand for two days, after which they are taken away and properly hardened off, when they will soon show flower. This mode of treatment I have pursued for three years with excellent results, and by it the bulbs come sooner into flower than they would do managed in any other way.

G. DAINS.

Rayner's Penn, Amersham, Bucks.

Tying Hyacinth Spikes Together.—Mr. James Cutbush, of Highgate, the well-known Hyacinth grower, protests against this practice in the "Gardeners' Magazine." To prevent any misunderstanding, let me say first of all that I am alluding to the practice of tying two or more spikes together to give them the appearance of one large solid spike. In my opinion, this practice must lower the tone that all exhibitors should have when showing a specimen of any plant for exhibition. If we are to do our best to try to deceive the public by forming one large spike with several small ones, and the theory that it is legitimate to do so is to become the order of the day, we shall have to retrograde instead of going forward, and get the old-fashioned varieties that are noted for splitting, and which have long been discarded by all genuine lovers of the Hyacinth. When a Hyacinth throws up more than one spike it is not a single bulb, but two or more confined within an outer sheath, and which is in reality the first stage towards a natural division. The bulb has, whether prematurely or not, become too old for the market, and the two or more portions contained within its outer covering have, of course, not attained sufficient strength to produce a perfect spike. It is "perfect spikes" we want on the exhibition table, to show those who attend the exhibitions what can be done by the selection of good bulbs in the first instance, and by skilful culture afterwards.

Sparmannia africana, an Ever-blooming Plant.—Having a fine specimen of this in great beauty, allow me to recommend the cultivation of this truly lovely plant to all who possess a cool greenhouse or conservatory; its great merit is that of being always in bloom. Ever since it opened its buds, on arriving from Sierra Leone, nearly three years ago, it has never ceased, winter or summer, to produce its rich masses of white flowers. The sepals of the calyx are fringed with delicate hairs, and with the petals falling back the filaments stand out very prominently, yellow at the base, and terminating in a fine crimson colour. The foliage is of a pale green hue, large, and heart-shaped; a profusion of hanging buds are always ready to supply the place of the fallen flowers. It is an arborescent shrub, belonging to the natural order Tiliaceæ, and was first noticed by Anders Sparmann, a Swedish botanist and traveller, in the year 1799. From its bearing a temperature as cool as 34° without suffering, I incline to think that it must have been introduced into the tropics from the Cape of Good Hope, which is probably its native habitat. My plant is 5 feet in height, though only in a pot. It

is readily increased by means of cuttings struck in bottom-heat, in loam and peat, under a hand-glass. No seeds of this plant have as yet come to maturity with me.—E. W. C., *Glen Andred*.

Araucaria Balansæ.—According to Mr. Balansa, the discoverer of this splendid tree, it attains a height from 130 to 160 feet. He found it growing at an altitude of about 1,500 feet, in the forests on the south-west table-land of Unio, Cape Bocage, and on the volcanic hills of Duperré Bay, New Caledonia. It has the habit of the well-known *Araucaria excelsa*, which, however, it appears to exceed in beauty, and the rich purple-brown of the upper side of the branches of the plants which we saw at Mr. Linden's, renders it peculiarly elegant. The leaves are imbricated all around the distichous, simple branchlets, which are pendulous at the tips. They are scaly, not exceeding a quarter of an inch in length, ascending, curved, triangular, slightly obtuse, somewhat tetragonous and four-furrowed. Messrs. Brogniart and Gris describe the male cones as $1\frac{1}{2}$ to 2 inches long. This fine species has at length been introduced in a living state, and is now in Mr. Linden's collection; it will probably be followed by other new and curious Conifers from the same region, so rich in vegetable wonders. The first plant imported was exhibited at Florence in 1874, under the provisional name of *A. neo-caledonica*. A closer examination has enabled us to identify it with *A. Balansæ*.—E. A., in "Illustration Horticole." [There is a striking plate of this plant in the last issue of this journal.]

Forcing the Flowers of *Magnolia conspicua*.—An accident gave me an opportunity of securing a large supply of the beautiful flowers of *Magnolia conspicua* during the months of January and February. A grand old tree here required (for reasons that need not be stated) to be considerably cut in; this was done after Christmas. I put all these loppings into a large tank under the stage of one of my houses, and very soon afterwards the buds began to swell, and ultimately they opened splendidly. The first hundred or so were remarkably fine, but the later flowers were not so good—an intimation of exhaustion on the part of the branches that produced them. Nevertheless, they were worth having to the very last, and the supply continued about five weeks, during which we cut a great number of flowers. In practising this system, the branches must be cut large to develop the flowers in water. Mine were flowered in heat from 60° to 65°.—R. OUBRIDGE, in "Gardeners' Magazine."

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Disrooting Camellias.—In reply to Mr. Baines (see p. 232), allow me to say that my object in disrooting my Camellias was to show what an amount of reducing the plants would endure. Having more than were required for planting out, many were pruned, and much closer than was previously stated, so close in fact, as to get them into pots 18 inches across. They have all done well, with good feeding.—H. GADD, *Wollaton, Notts*.

A Novel Mode of Preparing Soil for Potting.—We find the following under the heading of "House Plants" in a popular and excellent family magazine:—"Ladies who find their efforts to raise house plants frustrated by worms, may be able to win success by boiling the earth before setting the plants. Use little water, and allow it to simmer away after a few minutes of hard boil."

Camellia Jardin d'Hiver.—Having grown this both planted out and in a pot for some eighteen or twenty years, I find that, like many other Camellias, not excepting the double white, it has defects as well as merits. Being extremely pyramidal and compact in habit, the flower-stalk is too short for gathering; the flowers, also, when expanded, are a little deficient in the centre; therefore, as there are reds in abundance, I would not recommend it.—C. E. I.

Dendrobium heterocarpum.—This sweet-scented Orchid, reminding one of the odour of *Pergularia odoratissima*, or *Cymbidium aloifolium*, has greenish flowers, with a brownish-crimson lip; a combination of colour very novel and very beautiful. It is a free-growing Orchid, and, although pot culture is a convenient way of growing it, I prefer placing it on a block of wood, on which the flowers are shown off to advantage; and the "life-in-dry-bones" look which the plant possesses renders it an object of unusual interest.—CHEVALIER.

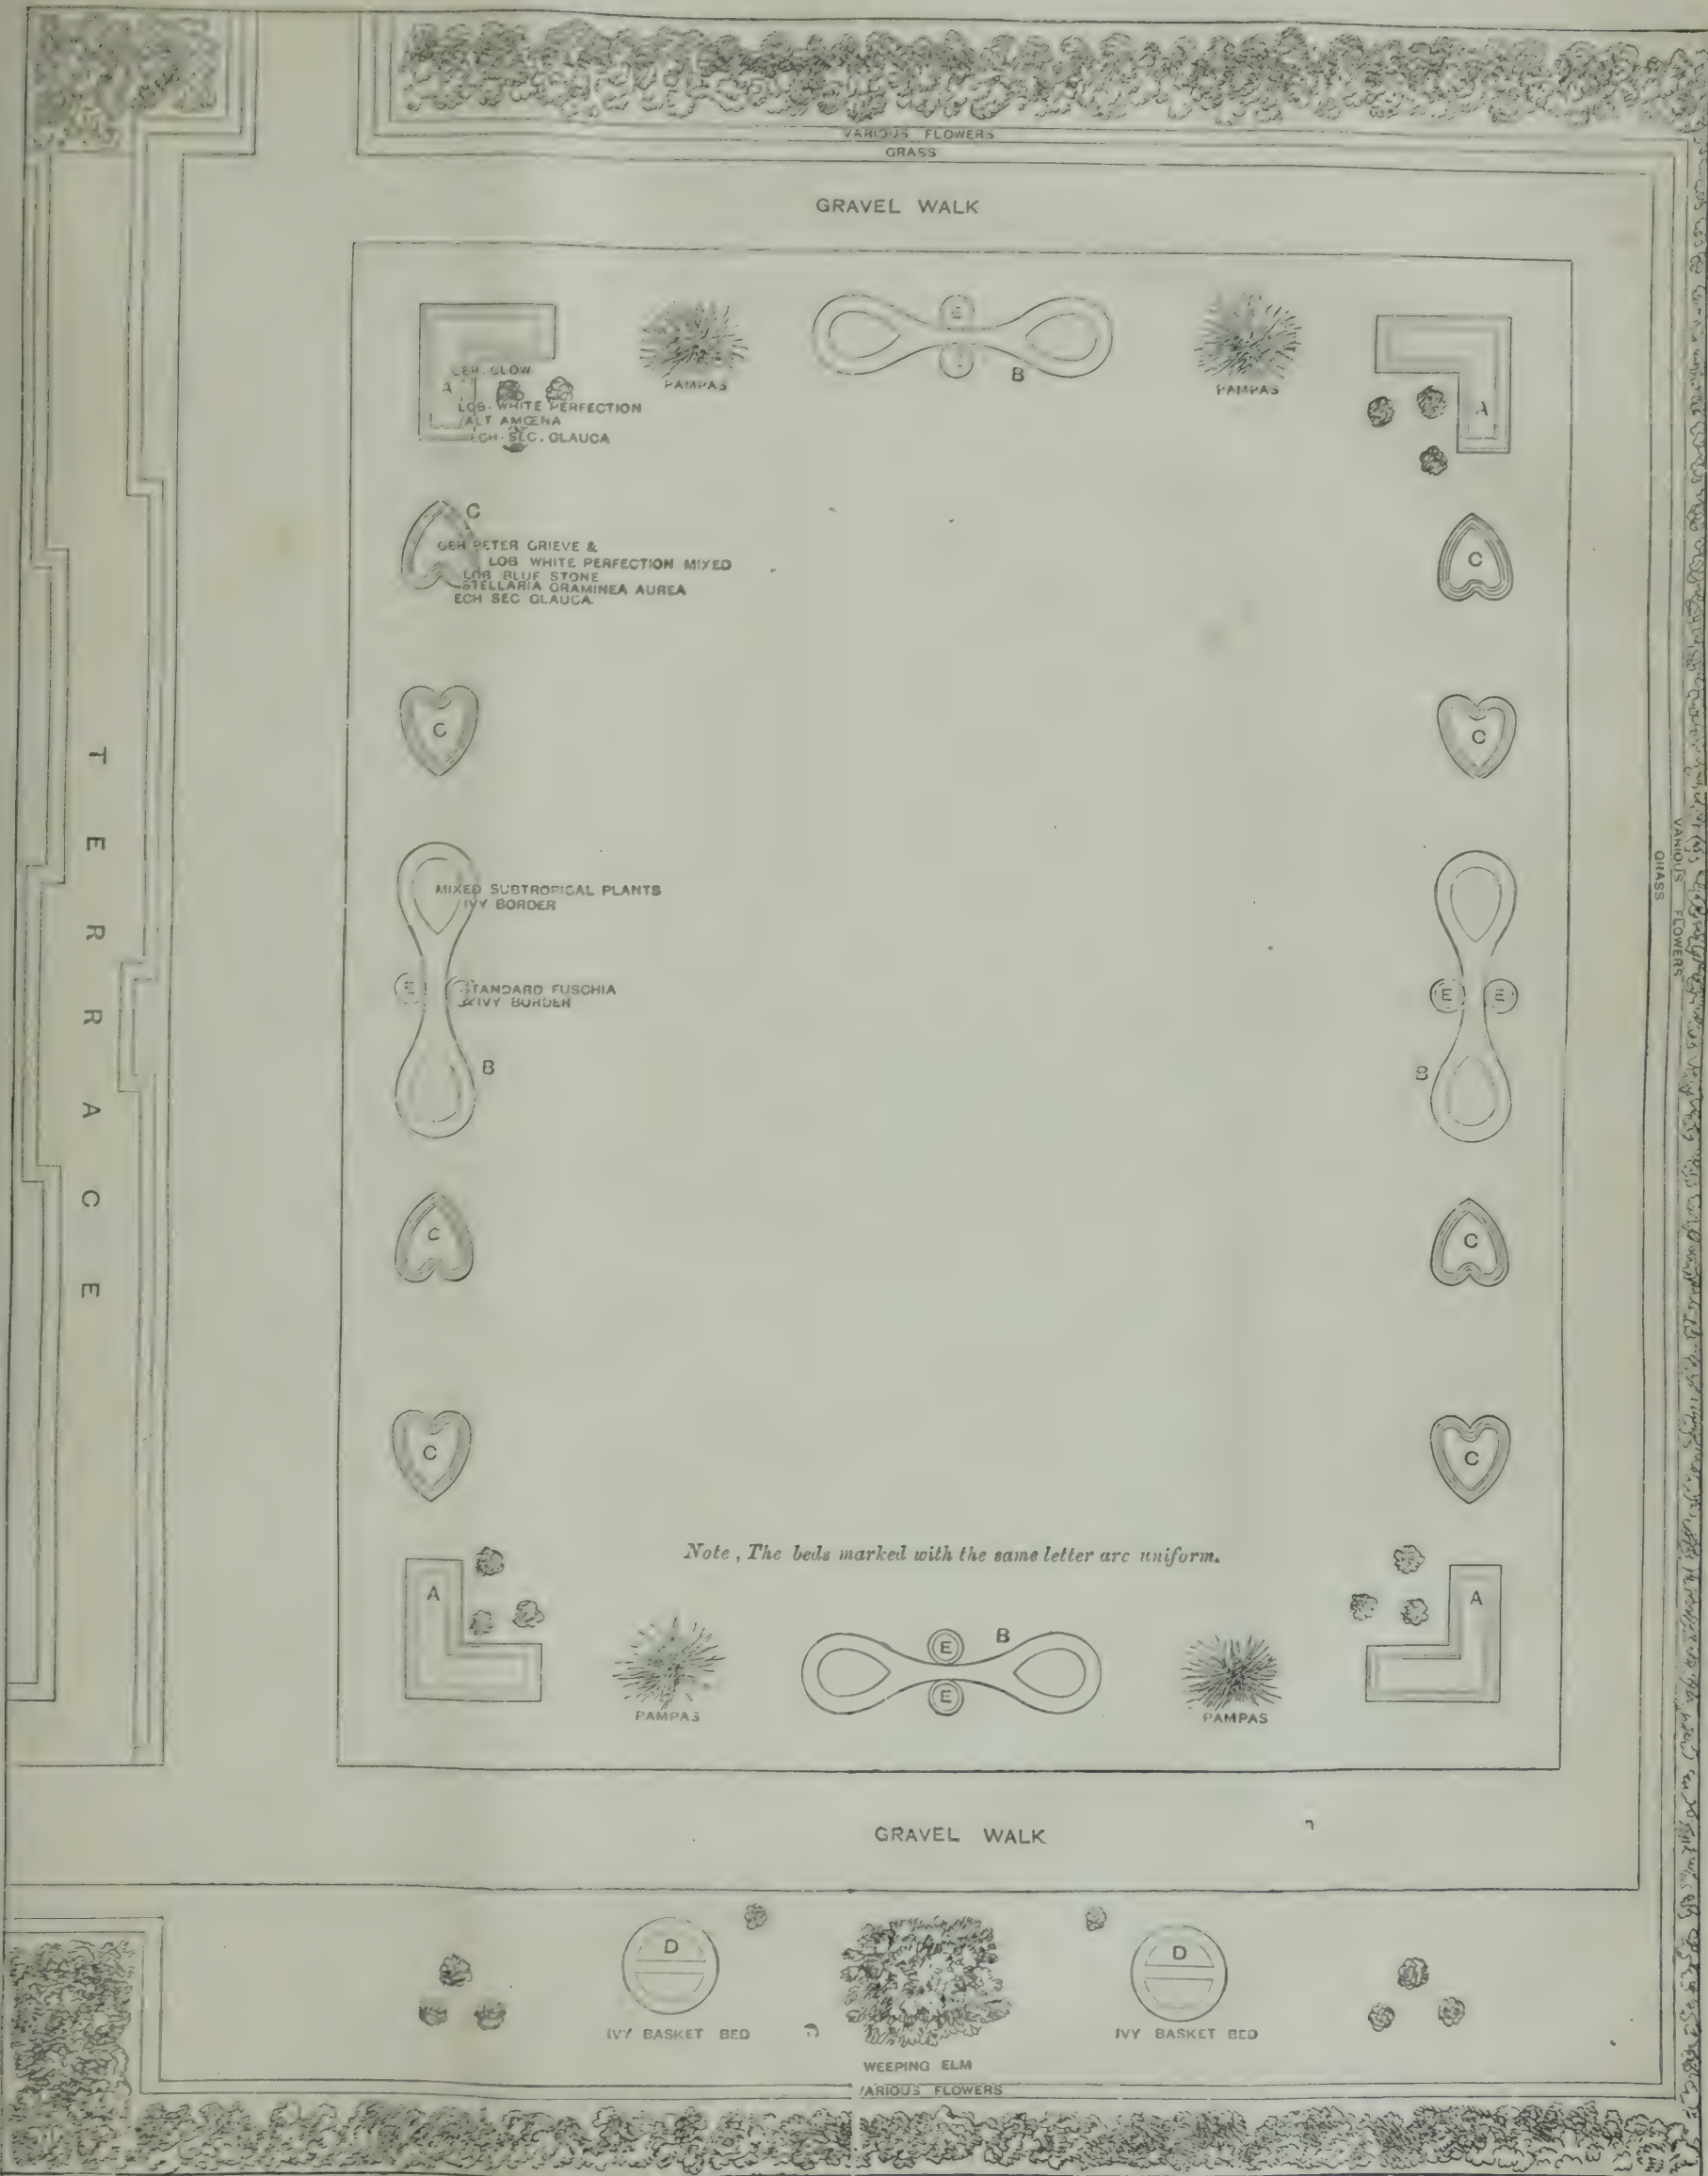

Wintering Bedding Geraniums.—The mode of wintering rooted cuttings of these (recorded at page 200), although differing from what I have seen done elsewhere, is not altogether new. Seven or eight years ago, when visiting the gardens at Cadland, I found that such cuttings were first struck in the open ground; then they were lifted, and around the roots of each a small handful of Moss was tied with a piece of bast. These were then stored thickly together in frames, or in boxes, in the houses; and, when put out in the spring, were laid in thickly on a shallow bed of ashes, and from thence moved with balls of roots to the beds. By this plan, the saving in pot-room and labour was more than can well be realised.—A. D.

Blue-flowered Hardy Plants under Glass.—Of these I have now in bloom, in pots, *Iris reticulata*, rich purplish-blue (previously mentioned by me); *Scilla sibirica* and *bifolia*, both rich shades of blue; Grape Hyacinth, bright Oxford blue; *Myosotis dissitiflora*, lovely cerulean or Cambridge blue; and, deepest and richest of all, *Lithospermum prostratum*. All these flower well in pots; but, perhaps, the *Lithospermum* is the most difficult to deal with. My plant of it, which has been in a pot for two years, now fills a 10-inch one. It thrives well in turfy loam mixed with a little leaf soil and silver sand. It has been in a cool-house all the winter, and well does it repay that care, being six weeks earlier in blooming than usual. As a hardy rock plant, it is, as regards colour and habit, unrivalled, and should be found in every good garden.—A. D.

THE PRINCESS TECK'S FLOWER GARDEN.

THE accompanying plan represents a square on the east front of the old Royal Palace in Kensington Gardens, surrounded by a belt of deciduous-flowering and evergreen shrubs, the rectangular piece of lawn in the centre being laid out as shown in our illustration. The beds around the margin are gay in summer with flowering plants, the bright colours of which are toned down by the cool green turf and surrounding belt of shrubs. The two circular basket-shaped beds on the south side, and some of those on the lawn, are surrounded with Ivy edgings, an arrangement by which a pleasing effect is produced, not only during summer, but also in spring, when these beds are full of Tulips, Hyacinths, and other early-flowering bulbs. Thousands of bedding plants are raised here for the decoration of Hyde Park, St. James's Park, the Green Park, and last, but not least, for the gay little semicircular parterre in front of the Ivy Cottage in Kensington Gardens. These consist of such things as *Kleinias*, *Pachyphytums*, *Lobelias*, *Alternantheras*, *Stellaria*, *Pyrethrum*, *Golden Feather*, and plants of a similar character; while such foliage plants as *Acacia lophantha*, one of the most graceful of all green feathery-leaved sub-tropical plants, *Musa Ensete*, and *Acanthus latifolius* are being raised from seed. In some of the larger houses are hundreds of large Musas, Arads, Cycads, Pandanus, and great fan-leaved plumose Palms, destined to ornament some of the most sheltered parts of Hyde Park during the coming season. In the frames outside are thousands of zonal and other bedding Pelargoniums, Echeverias, Sempervivums, Mesembryanthemums, and other succulents, nor do these monopolise all the resources of the establishment, for a fine stock of Peonies and other herbaceous plants is being got together for re-planting the long flower walk in Kensington Gardens. In one of the frames we noted half-a-dozen plants of the round-leaved *Saxifraga ciliata*, a kind well deserving of pot-culture, its waxy salmon-tinted flowers being freely produced at this season, and they last so well after being cut that it is surprising they are not more frequently employed in bouquets and other floral arrangements than they are. These plants, under the care of Mr. Cole, are judiciously and skilfully managed. Unsightly walls here and there have been trellised, and ornamented with creepers, and on the lawn, as will be seen, are many interesting specimen plants, but so placed as not to interfere with the open centre of green well kept turf.

The Nurseries of Ellwanger & Barry.—In a recent number of the "Daily Graphic," an illustrated American paper, there are published some illustrations of Messrs. Ellwanger and Barry's great nurseries at Rochester. America is largely indebted to these enterprising nurserymen for much that is valuable in horticulture. Recognising in the soil of the region of country bordering on Lake Ontario a singular adaptation to the culture of fruit, and comprehending the future demand for it in the year 1838, they commenced business, about one mile from the centre of the city, and not far from Mount Hope Cemetery. Such was their success that in 1850 they had 200 acres under cultivation, and in 1860 not less than 550 acres of the richest land in the Genesee Valley. Previous to the first-mentioned date, Mr. Ellwanger commenced as a florist in Fitzhugh Street, in that city. They were among the first to import fruit trees from Europe; and, in 1844, Mr. Ellwanger himself selected large quantities, principally of dwarf Pears, from the different nurseries throughout Europe, which he sent to America. To Ellwanger and Barry is due much of the credit of encouraging the culture of the Pear, as being peculiarly adapted to that country. From this date to 1860, various other nurseries were established in their vicinity, until Rochester bore supremacy in the nursery business over the whole country. Its nurseries produced more fruit and ornamental trees, shrubs, &c., than the combined nurseries of the United States. In the midst of competition Messrs. Ellwanger and Barry have pre-eminently retained their high position for integrity and intelligence. This firm keep 25 acres of land solely for testing new varieties. In the department of hardy ornamental trees, shrubs, Roses, and other plants, their collection is the most extensive and complete in the United States. Their specimens of the "big trees" of California, or *Sequoia gigantea*, are the best to be found this side of California. Mr. Barry is the author of "Barry's Fruit Garden," a standard text book. He was also for some years editor of the "Horticulturist," and has written for publication a great deal that is valuable. In 1839, they published their first descriptive catalogue, which they still continue to issue annually.

THE PRINCESS TECK'S FLOWER GARDEN AT KENSINGTON PALACE.

THE FRUIT GARDEN.

COOKING PEARS.

THESE may safely be classed with neglected fruits in many gardens; while in comparatively few are their merits fully recognised, their only representative too often being some broken-down specimen of the Iron Pear that has stood for an indefinite period in the most remote corner of the orchard. I find, however, that culinary Pears repay any little extra care bestowed on them; quite as much, or even better, than many dessert kinds. In the first place, they are extremely hardy and vigorous, Uvedale's St. Germain alone requiring the protection of a wall. The others succeed well, as espaliers, pyramids, or dwarf standards; but if allowed to grow very tall, especially in exposed situations, the fruit is liable to be damaged by wind; that is, if it escapes being blown off altogether. Culinary Pears are also regular and abundant croppers, and, unlike many of the dessert kinds, which, except in abnormal seasons, fail to ripen at the proper time, they are fit for use as soon as they are large enough, and continue in usable condition as long as there is any demand for them. They may be kept in any ordinary fruit room from October to May, without scarcely any loss from decay; and, with extra care they may even be preserved in a sound state until late in the summer. However, as soon as bush fruits become plentiful, the demand for culinary Pears ceases. It is when preserved fruits form the principal supply of the kitchen, that these Pears are most appreciated. Where they are disliked, it is generally the particular variety supplied that is at fault. I have frequently seen it stated that the better the sort of dessert Pear the better cooking Pear it makes. If this be the case, I have not yet met with the right kind. But, allowing that to be the case, we should still cultivate cooking varieties for culinary purposes; for, although last year Pears of all sorts were most abundant here, yet, last February, dessert kinds in season were too valuable to be spared in any quantity for kitchen purposes; while cooking varieties, properly so called, were as fresh as when gathered. The culinary sorts most esteemed here are Uvedale's St. Germain, Catillac, Verulam, Gilgil, and Morel. There are other kinds equally good, but, as such Pears are all excellent keepers, it is useless having too many varieties when a few that can be depended upon give satisfaction. They are as superior when cooked to the dessert kinds as the dessert kinds are to them for eating. It may be argued that some of our best dessert Apples are also good cooking Apples, but very few among sweet kinds equal the Wellington, that is, if that variety be considered only as a kitchen Apple. It is one thing to have the best variety of each fruit for each special purpose, but another to make shift with something that will answer that purpose, simply because nothing better is available. In many cases make shifts of this kind are so many bars to progress. This is a good time to graft any unfruitful or worthless varieties, by which means a bearing tree is quickly obtained and double grafting generally tends to extra fruitfulness.

JAMES GROOM.

Henham Gardens.

GRAPES IN UNHEATED STRUCTURES.

MR. TILLERY's last year's experience in this matter, at Welbeck, is thus recorded in the "Florist":—"A collection of hardy Grapes, on a glass-covered wall here, ripened during summer and autumn to the best crop I have ever grown under such conditions. Although such warm favourable summers as that of 1874 only come at intervals, still there are some kinds of hardy Grapes that, with a little attention in protecting them in the cold spring months, when budding or in flower, will produce ripe Grapes in our ordinary summers. The glass-covered wall here, where the hardy Grapes are planted, has only artificial heat applied to it when the Peaches and Nectarines are in flower, so that the Grapes have not the same advantage at their blooming time. I will commence with the white Grapes, as they were the earliest in ripening. The early white Malvasia, or early Kienzheim of the Royal Horticultural Society, ripened perfectly in the middle of August; this sort seems to me to be synonymous with the Grove-end Sweetwater. Royal Muscadine, or the Chasselas de Fontainebleau of the French, ripened in the end of August, and is one of the very best early white Grapes. Early Smyrna Frontignan is a Frontignan-flavoured Grape, and ripened as early as the Royal

Muscadine. Early Saumur Frontignan is another very early-ripening Frontignan-flavoured sort. The Prolific Sweetwater and Buckland Sweetwater ripened in the end of September, and got to a fine amber colour in October, and their flavour was excellent. Of early black Grapes, the Sarbelle Frontignan, a purple Frontignan-flavoured variety, ripened in the beginning of September, but it has only a small bunch. The Esperione or Espiran, the hardiest of the Black Hamburg section, ripened in the middle of September, and was finely coloured. The Welbeck Black Tripoli ripened in the middle of October, the bunches being as fine as some of the same variety grown in the vineries. To show that the summer of 1874 has been particularly favourable for ripening Grapes in unheated structures, I may state that two plants of the Muscat of Alexandria which were planted out in mistake with the hardy sorts both ripened their bunches; the Grapes were not very highly coloured, but perfectly Muscat-flavoured and good. A plant of Pearson's Ferdinand de Lesseps Vine likewise, lately planted out in the same collection, has borne some bunches this year, and promises to bear well as a hardy Grape. Some of the above varieties of hardy Grapes will ripen their fruit, even in bad seasons, in all our southern counties, if planted on a south aspect on walls or buildings. There cannot be a finer ornamental climber on a poor man's cottage than a Vine, whether in leaf or in fruit, but it requires attention in nailing or tying it to the walls, and in properly thinning and stopping the shoots every year. If allowed to grow wild, it gets battered about by the wind, and is then both unsightly and unproductive. There is no occasion for making expensive borders in which to grow hardy Grapes out of doors, for if the soil is anything at all of a fertile nature and drained, they will succeed well on it. In planting them in unheated structures, it would perhaps be better to give them a newly-made border, if the natural soil is not suitable or drained, with the view to the production of good-sized bunches and well-flavoured berries.

FRUIT VARIATIONS.

A GREAT deal of speculation is naturally indulged in by horticulturists when they see flowers or fruits growing out of the usual course of Nature. The changes from single to double flowers, the transformation of stamens and pistils to petals, and, again, the changes of some of these organs into green leaves, and new flowers bursting from the germ—these and many similar changes are too frequent, and take place too regularly to be fairly classed as monstrosities. There are, however, some other changes less frequent, and more out of the usual order of Nature, that may properly come under this head. Last summer we received from a correspondent specimens of Apples from the same tree, a part of the common round and regular form, and a part with a neck like a Pear, as shown in the accompanying illustrations. These Pear-shaped Apples were precisely similar to the round ones in colour, texture, and flavour; yet some insisted that they were produced by crossing with a Pear which grew not far off. We are not aware that crosses were ever produced between the Apple and the Pear, and we saw no indication whatever that these Apples were thus obtained. Since that time we have met with another curious deviation from the regular course of Nature, in a large number of Apples grown on a tree of the Fall Orange or Holden Pippin, a part of the surface of each specimen presenting the usual appearance of a smooth green or yellow skin, and another part covered with thick russet, with an abrupt margin between the two, the russeted parts being enlarged about a tenth of an inch. Some of the Apples thus affected had but a small portion of russet; others were nearly covered with it. Some had one-half russet—sometimes in a nearly straight line, and on others a broad belt extended around the fruit. In short, it appeared to be applied in various ways, though never in spots or small patches, but in broad portions and always extending around the fruit. Wishing to know how the appearance of these curious specimens would strike others, we sent some to a few distinguished horticulturists. One of them wrote:—"At one time we did not consider it possible for a mixture of the pollen to affect the fruit farther than the seeds; but, in the light of more recent experience, we think it possible for the flesh and pulp of the fruit to be affected as well as the seed, or such a 'sport' may have come from the stock as a graft hybrid. We can at best but speculate on a case of this kind. Mr. ———, who seems to interpret all these anomalies literally, would say it was a clear cross between a Russet and a green-skinned Apple." Mr. Fuller, in the "Rural New Yorker," says, in a general way:—"The Russets may have originated from the Pippins, or *vice versa*, and an occasional reversion to the original parent in some specimens would be no more wonderful than similar freaks met with among other plants. We have what are called 'sports' in nearly every genus of cultivated plants—white Roses that have originated from a 'sporting' branch of a red Rose, and the reverse of this; and, although the peculiari-

ties of these bud variations may remain permanent in the main, still a reversion to types does occur more or less frequently. If we take this view of the case, which to us seems to be both rational and natural, the presence of a Pearmain on the same twig with a Russet, or even a mixture of the two in the same specimen, like the one sent us, is by no means to be considered a surprising freak of Nature. We are well aware that many will take an entirely different view of this subject, and attribute the cause to the effect of fertilisation of the flowers. If a Russet Apple is found growing on a Pearmain tree, it would be at once claimed that the former supplied the pollen which fertilised the stigma of the individual flower producing the specimen so varying from the normal type. But horticulturists have made altogether too few experiments in this field to give us sufficient materials for determining the influence of the pollen of one plant over the envelope which encloses the seeds of another." As for the immediate causes of the abnormal developments to which we have referred, we have long been of the opinion that they are not caused by union in budding or grafting, or by cross-fertilisation,

Ordinary-shaped Apple.

Pear-shaped Apple.

but by various external influences. The Sweet-and-sour Apple is obviously caused by a diseased or imperfect development of a portion of the fruit, similar to the diseased or defective growth in Ribbon Grass; and many of the monstrosities mentioned are known to be caused by cultivation or stimulated growth. The Pear-shaped Apple, which we have figured, has doubtless been produced by some unknown external influence. The immediate cause of the large russet coverings and belts in the Fall Orange Apple was evidently produced by a fire, which slightly cooked the Apples, when small. A large brush heap, 20 feet distant from the Apple tree, was burned during our absence, and the heat was sufficient to give a brown surface to the most exposed sides of the young fruits when about 1 inch in diameter, without destroying them, and only slightly crisping the foliage. These browned Apples were the only ones affected with russet, but not on the exposed sides, for the russet

Apples with semi-Coverings and Belts of Russet.

covering extended around them equally on both sides. In what way the heat caused the development of russet, we leave physiologists to tell us; a repetition of the experiment on different fruits, by different kinds of heat, may possibly yield some curious results. The past season was the only time in which this russet was ever developed on them.—"Cultivator."

Two Good, but little known, Strawberries.—There has lately been a good deal of discussion respecting Keen's Seedling, which, in times gone by, and previous to the introduction of the many improved kinds now in cultivation was certainly not devoid of merit; but now a-days, when we have such handsome, large, and exquisite kinds as President, Sir Joseph Paxton, Early Prolific, and Duke of Edinburgh, all of which are good bearers, Keen's Seedling has been, to some extent, superseded. To those, however, who still prefer it to other kinds, I would say try Dumbarton Castle, which is apparently a seedling from it; both in foliage and earliness it resembles it, but its fruit is so irregular in size; it is also an enormous bearer, and may be depended upon under all circumstances. I am unacquainted with its origin, but believe it was raised in Scotland, and sent out by Messrs. Lawson. Whilst I have wholly discarded Keen's Seedling from my attention, I am so well pleased with Dumbarton Castle that I shall largely increase it both for out-door culture and for forcing. Another valuable Strawberry is Waltham

Seedling, for which we are indebted to Mr. Wm. Paul. This was only sent out a few years ago, and owing, no doubt, to that circumstance, is as yet but little known. It is, however, a great acquisition, being both hardy and vigorous, and its fruit, which is handsome, is excellent in flavour, and travels well. I have this year put a number of it in my Strawberry-house, and am pleased to say that it likewise bids fair to be one of the best kinds which we possess for early forcing.—FERDINAND GLOEDE, *Effendorf, Hamburg.*

Many Varieties of Pears on one Tree.—Some years ago, happening to call at a rectory in Lancashire, where much attention was paid to gardening, I saw what I consider a most excellent plan for growing a large collection of Pears, of which at least one hundred varieties were produced in a limited space. The outside boundary-wall of the garden was perhaps 12 feet high, which was, on the south side, devoted to these trees, and upon it there may have been from ten to twenty of them, perfectly trained upon the horizontal system. Originally, there may not have been more than one tree, or perhaps two, of any particular kind, which gave, as is often the case, a glut of fruit, one-half of which was certain to decay before it could be consumed. Each of these trees, however, are now made to bear from ten to twenty varieties, by grafting. Some half-dozen of the branches were sawn off, about 6 inches from the bole, and grafted with scions from choice Pear trees, of both early and late kinds. Assuming that there were twelve trees, and upon each were ten grafts, 120 varieties would thus be produced, and this number would, I imagine, be enough to satisfy any grower, however capable his grounds might be for extensive operations of this kind. It is scarcely necessary for me to point out the advantages of the system I have here referred to. Its utility for testing varieties, as regards adaptability to soil, situation, &c., will be recognised at once, but I may mention that Pears from this particular wall were frequently exhibited at the Horticultural Societies' shows, and commented on favourably by the late Donald Beaton.—THOS. WILLIAMS, *Ormskirck.*

Curious Affection of the Vine.—I carefully perused the article in your columns headed "Vine and Peach Tree Destroyers" (see p. 189) in order to see if the *Otiorynchus* mentioned was a grub which came under my notice last summer; but I find that my enemy is evidently of a different kind. Last year, about this time, when the Vines in our second Vinery were starting into growth, I noticed some warts about the size of a Broad Bean on several of the rods; but as the Vines were in active growth, I left them alone. The result was that, by November, several of these warts had attained the size of a goose's egg, but a great many of them seemed to dry up. When pruning the Vines last December, I pared the large warts completely off, and in all of them I found little fat maggots embedded close to the stem. Eight was the most which I found in one wart, and two the least number. They were perfectly white, with yellow heads. I treated them as I do all weevils and grubs, viz., killed them. The Vines did not seem to suffer in the least last year from the warts, nor do they bleed now from the hard-paring to which they were subjected. I should esteem it a favour if you would tell me what the maggots are, and if I may expect them to appear again this year.—DOUGLAS BROWN, *The Gardens, Mocollop Castle, Ireland.* [Mr. Brown's communication is very interesting, for nothing like the galls he describes seem to have hitherto been published. Audouin, in his large work on the insects hurtful to the Vine, takes no note of them; and Kaltenbach, in his recent *Pflanzen-feinde*, alludes to nothing that can be supposed to be them. We are all familiar with excrescences on the Vine, but these are caused by hypertrophy. We are, therefore, so selfish as sincerely to hope that Mr. Brown may have a fresh crop of warts this spring; and we trust that if he does, he will not fail to send us specimens both of wart and insect. It may possibly be some insect not natural to the Vine, such as *Ceutorhynchus assimilis*, which makes galls on the Cabbage-stalk, which has changed its habits and abjured its nature.—A. M.]

Storing Fruit.—The result of the various experiments of members of the Pennsylvania Fruit-growers' Society in keeping winter fruits may be summed up as follows:—Take the fruit from the trees as soon as matured, pack in wooden cases, and store in a temperature as low as possible, so that it shall not freeze. The great point is to have the fruit fully matured when picked from the tree; and it was stated by one or two that the atmosphere must be entirely dry, and yet the most successful fruit grower in the southern part of the state decidedly advises moisture in the air. He prefers a "spring-house," or one near running water. All apartments in which fruit is stored should be in every case thoroughly ventilated. Mr. Brinton eulogised the practice of packing the fruit in barrels in the orchard, and leaving it there until severe weather. Mr. Stetzel spoke of a complete fruit-house in Reading, where the fruit is packed in boxes and placed in an apartment in an ice-house, so that the temperature is preserved even and very cool. Fruit is kept in this way from one season to another. This arrangement is a

modification of the Nice system, and more simple and cheap. Mr. Engel said that failures often result from fruit being taken from sickly trees.

Pruning Peaches and Nectarines.—In pruning Peaches and Nectarines, what length of shoot, and how many fruit buds on a shoot, should, as a general rule, be left?—M. W. [In pruning Peaches and Nectarines in winter the first rule to be laid down for a basis for all the rest, is to shorten every shoot in proportion to its strength, and to prune to where the wood is firm and well ripened: this will cause all the pithy and unripened wood to be removed, thence causing a supply of that which is better ripened for the ensuing year. But in order to give every facility to the ripening of this wood, it must be trained thin; not in profusion according to the general custom, but such shoots only as may be required for the following year. Trees which have arrived at a bearing state should have their strongest bearing shoots shortened to 12 or 14 inches, those next in strength to 8 or 10, and the weaker ones to 4 or 6 inches, pruning each to what is termed a treble eye, or that where there is a blossom bud on each side of the wood bud: where branches are not in a bearing state, these treble eyes will not be found; they must therefore be pruned to a wood bud alone, which is always known by its sharp point].

New Pears.—Antoine Delfosse and Beurré Gambier are the names of two New Pears mentioned by M. Charles Baltet in the last number of the "Bulletin d'Arboriculture." The first was raised in 1863 by M. Grégoire, of Jodoigne. The tree is of moderate vigour and very fertile; the fruit rather large, of a truncated pyriform shape. The colour is a dark greenish-yellow, with tawny spots. The flesh is melting and juicy, and of most exquisite flavour. It ripens during the second fortnight of November. The Beurré Gambier was raised by M. Gambier at Rhode St. Genèse. The tree is moderately vigorous upon the Pear stock, but weak upon the Quince. The fruit is large, and resembles in shape the Beurré d'Hardenpont and Doyenné d'Hiver. The skin is smooth, and in colour green suffused with rose upon a yellow ground. The flesh is melting and agreeable. The fruit ripens from the end of December to the end of January; and, hanging long upon the tree, should be gathered late.

The Howell Pear.—This is a New England Pear, and is now well known and appreciated. Its merits, however, are perhaps more generally understood in Southern Illinois than anywhere else, as hundreds of trees of this variety are bearing fruit there, and paying their owners as handsome a profit on the investment as any other variety in that State. It does exceedingly well at the East, too, embracing that great essential to popularity—early bearing, one of the merits belonging to the Bartlett. A tree of the Howell in full bearing (says Mr. Hoopes, in the "New York Tribune") is a sight worth going some distance to look upon. The large fruit, distributed evenly over the tree, with a beautiful yellow ground, heightened by a rich, ruddy-red cheek, leave nothing to be desired excepting a luscious, melting, juicy flesh, and all this it claims as well. It reminds one more of the old White Doyenné in its ancient dress than any variety of modern introduction. It has been said that it is addicted to the blight, but the weight of testimony is rather the other way.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

A Roundabout Way of Testing Fruit.—In the "Revue de l'Horticulture Belge," M. Banchet describes a test for ascertaining the quality of a Pear. It, says he, you can write on it easily with pen and ink, it is a good Pear. Other Pears, whose rind does not take the ink so well, are inferior in flavour.

The Best Plunging Material.—The best plunging material with which I am acquainted is sawdust from green wood. We have here two Pine pits heated with dung linings, but since using sawdust the linings are dispensed with.—R. GILBERT.

Beurre d'Esperen the Best Late Pear.—This is the best late Pear; here it does well on pyramids and, unlike Glou Morceau and Beurré Rance, which are liable to crack, the Beurré d'Esperen is smooth and really good from January to March. It is also a free and excellent cropper. Ne Plus Meuris in some localities is fine in flavour, but here on a west wall it is simply useless, except for baking purposes. I am trying the finer varieties of French Pears on single stems planted 5 feet apart against a south wall. I also intend trying some of them with three stems. Four years ago I planted two dozen to be trained over arch-ways, and they have fully answered my expectations.—R. GILBERT, *Burghley*.

Glass Copings and Frost.—Those who depend upon glass copings keeping out 10° or 15° of frost (see p. 213) will be sadly deceived. During the late frost, our late Peach-houses fell to 30° when there was 20° of frost outside, though the heat was not turned off till 10 p.m. When not fired at all, they fell to 31° in the morning with 7° of frost outside. When more than this, and less than 15° of frost, the soil of the borders got frozen, and bedding Geraniums had to be covered with mats. An iron conservatory here falls to 32° without fire-heat when there are 5° of frost, and I have seen Peach-buds frozen and Strawberry plants quite hard in a Peach-case, shut up early without heat, with 15° of frost out of doors. Dry frigi domo will keep out more frost than a glass case, if sheeted from the coping to the ground; when wet and frozen, it is not much, if at all, inferior to glass as a protector. Straw mats are the most effectual protectors of all.—J. S. W.

THE NEAPOLITAN CROCUS.

(CROCUS IMPERATI.)

THIS lovely species, without a rival in its own genus, and holding its own as a gem of gems among all spring flowers, appears to have been first introduced into this country by the Hon. Mr. Fox-Strangways, afterwards Lord Ilchester, who states that "it grows in profusion all about Castellamare, La Cava, and Salerno, and other parts to the south of Naples, in every hedge-bank to the height of 2,000 feet, or more, above the sea. It is wonderful that so fine a plant has not attracted more notice than it has done in such a frequented country." Well might he make this remark, for anything more strikingly beautiful than the combination of colour afforded by the delicate fawn of its purple-striped outer petals, and the soft mauve of their inner side, it would be difficult to conceive. The exquisite little *Crocus minimus* of Corsica, and the lovely *Crocus biflorus striatus* which studs the Grass plots of the Boboli Gardens, at Florence, are very beautiful, but they cannot compete with *C. Imperati*. This pretty species seems to have been well known to that first and foremost of *Crocus* growers, Dean Herbert; but, since his time, it seems strangely enough to have been totally neglected, and almost, if not quite, lost to cultivation till the last few years, when the floral world

Stigmas, Anther, Corms, and Section of the Leaf of *Crocus Imperati*.

has been awakened to its merits, mainly through the instrumentality of Major Trevor-Clarke, of Welton Place, near Daventry, who has, with great liberality, distributed it among his numerous friends. It may be said to form a link between the autumnal and Vernal Crocuses, for sometime before Christmas its leaves come well above ground, and by Christmas Day (often much earlier) its fawn and purple buds may be seen pushing up unchecked by frost, wind, or snow, and opening their exquisite mauve lips to catch every passing gleam of sunshine, when scarce an Aconite or a Snowdrop has thought of putting in an appearance. It is so hardy that nothing seems to hurt it. It lasts in bloom from Christmas to the middle of March. It increases rapidly under ground, and produces seeds plentifully. There is a white variety of it, which grows on the higher parts of the mountains near Naples, and which appears never to have been introduced to cultivation, a defect the sooner remedied the better. *C. Imperati* belongs to the *Odontostigma* group. *C. suaveolens* of Bertoloni, a native of the Valle d'Inferno, near Rome, which does not appear to be now in cultivation, closely resembles it, but it belongs to the *Holostigma* group; it has narrower petals, and the leaves appear at the same time as, and not before, the flowers. *C. Imperati* bloomed this year at Tooting with Mr. Barr and Mr. Parker, and from both these growers blooms of it have been received.

Drayton-Beauchamp Rectory, Tring.

733 NEAPOLITAN CROCUS.
(*C. Imperati*.)

THE KITCHEN GARDEN.

THE NEW RACE OF POTATOES AND THEIR CULTURE.

THIS valuable and well-known esculent, now so widely cultivated, is a native of the mountainous parts of tropical America, and was taken to Spain and Italy by early adventurers in the sixteenth century; for we read of its cultivation in those countries in the year 1550. The usual size of the Potato in its wild state is rarely more than an inch in diameter, and the flavour very insipid and almost unpalatable. When first introduced into Europe it created some excitement, of a similar character to that caused by the introduction of Tobacco and Coffee; for many years it was only to be found on the tables of the opulent, where it was used as a dessert either in the form of a sweetmeat or as a fruit. The first varieties grown in the United States were taken there from Europe. The quality was very poor, and not a variety then in use would at the present time be deemed fit for the table. It is only within a comparatively recent period that it has found its way into both Continents as a general article of food for man and beast, or has received attention from cultivators. Many of our most practical and foremost gardeners are now directing their attention and energies to its improvement and propagation. In the year 1845, the disease known as the rot appeared, and nearly destroyed the whole crop. About this time a few persons, among others the late Mr. Goodrich, of Utica, imported a lot of the wild varieties directly from South America, and proceeded to raise seedlings by crossing with the various kinds then in use. Many thousand seedlings were then produced, but few of them were ever brought to any state of perfection. One of the principal sorts saved was the Garnet Chili, which had a great reputation, and is the parent of many of our new sorts which are now attracting so much attention. Some fifty years ago, a cultivator who raised one hundred bushels of Potatoes was looked upon as having an enormous stock; while to-day, many growers in the vicinities of our large cities raise from ten to twenty thousand bushels, without exciting any unusual attention. Within this period nearly all the numerous varieties with which we are acquainted have been brought to notice, and every year adds its score of new seedlings to the already overgrown lists. Enormous quantities of Potatoes are now raised annually in this country, and the demand is always greater than the supply.

The following information, issued in their Potato catalogue, by Messrs. Bliss & Sons, who sent out so many of the kinds that have recently been proved so valuable cannot fail to interest Potato growers:—The uses of this tuber are numerous, apart from their principal use as an article of food. Thousands of bushels are annually manufactured into starch, and alcohol is distilled from its juices. Even sugar has been made; but with so much competition in this line, it has never proved a great success. Too much cannot be said in favour of this valuable staple, and we shall endeavour to instruct our readers in these columns as to the methods used to increase the supply, without increasing the expense of its cultivation.

Cultivation.

The soil acknowledged to be the best for the Potato is a rich loam, sandy, and neither too wet or too dry. A cool, moist soil will produce larger Potatoes, but the danger of too much wet is so great that a warmer soil is preferable in this climate. Early Potatoes reach their maturity sooner in a quick, light soil, and present a brighter and cleaner appearance, than when dug from that which is heavier. A calcareous formation generally yields a sure crop. Old sod land, well turned under in the fall, and lightly ploughed and harrowed in the spring, will produce a sound crop, and often an astonishingly large one. Clover sod for this purpose is excellent, and furnishes a large amount of vegetable substance to the ground. When turned under in August or September it will rot by the following spring, and only a top-dressing of some well-established fertiliser will be required to carry through the crop. Wet land produces a coarse, unpalatable article, and one of little value even as food for cattle. Barn-yard manures are of little benefit to such land. Lands should never

be ploughed while wet and heavy; it injures the soil and does more harm than the manure can offset. Prepare the ground as carefully and thoroughly for Potatoes as for any other crop. Attention in this particular well repays the cultivator. Land intended for Potatoes requires but little manure, and that should be old and well rotted. By many, spreading the manure before ploughing in the spring is thought to be the best mode. At the time of planting, bone-dust, ashes, plaster, marl, and like fertilisers can be used to great advantage with this crop, as they are of a dry or absorbent nature. On wet soils they are very beneficial, as they prevent disease as well as promote the growth of the tubers. On warm, dry, light land, muck compost may advantageously be used; decayed leaves are excellent. In seasons of disease among Potatoes, fields where ashes have been used have suffered but little from the rot. Potatoes are usually planted in drills or hills, the latter being the more common method in this country. Some varieties require more space than others. For drills, $2\frac{1}{2}$ feet by 3 feet is ample; while, when planted in hills, 3 to $3\frac{1}{2}$ feet is the usual distance. The latter method has some advantages, as the cultivator or horse-hoe can be used both ways of the field. Some of the earlier varieties may be planted closer without loss to the crop. Cover about 4 inches in light soil, and not so deep in the heavier. Cultivation should be commenced soon after the shoots appear above the ground, and weeds should be kept down with as much care as in a Carrot-bed. The earth should be drawn a little towards the hill at each hoeing, that the rootlets may gain strength and nutriment from the surrounding earth. When the blossoms appear, hoeing should be discontinued, and in fact is rarely necessary, as the stalks then cover the ground and discourage the growth of weeds. An excellent plan is to go over the field occasionally and remove carefully any weeds that appear in the hill, for they draw largely from the sustenance required for the developing tubers. Many farmers still continue to plant three to five eyes to the hill. In our opinion this is a mistake, and the last few years' experience confirms our views. Potatoes cut carefully to a single eye, the hills, perhaps, a trifle closer, will yield a larger crop than the careless way of throwing in seed by wholesale. We all know the effects of too close a growth of Carrots, Turnips, and such roots on the crop, and we think the same rule applies equally to Potatoes. Two good eyes to the hill, with a proper proportion of the flesh to each eye, will produce a far larger crop of merchantable tubers than two whole ones; will yield from one-third to one-half more in weight—an item of no small consequence—to say nothing of the saving of nearly one-half the seed. Any good cultivator, who is up to the times and reads the leading horticultural papers, will corroborate this statement. In order to secure an early crop, the seed must be planted as soon as the ground is in proper working order. This time differs in the various parts of our extended country, so that no set time can well be given. The earlier varieties can be marketed in sixty-five to seventy days from planting, thus competing successfully with southern crops of the more common kinds. A second crop can thus be planted, as described elsewhere, allowed to thoroughly mature, and thus have a good seed for another year, and a sound article of food for winter use. The yield of the first planting will give a handsome profit, for early Potatoes always command a high price when near a city or town. The later varieties do better when planted some weeks after the early kinds; and the cultivator has this advantage, he can get the former well started and cultivated before he turns his labour and attention to the latter. A common method of forcing Potatoes is to select whole, sound tubers of some early variety of medium size, placing them close together in a moderately heated bed, composed of either light loam or partially decayed leaves. This should be done several weeks—say three or four—before the time of planting. By that time the tubers will have started sufficiently to be set out. Cut the Potatoes into pieces as has been directed, and use care not to injure the young shoots. Plant 3 inches deep, apply a little horse-manure to the bottom of the hill, to afford warmth and to urge forward and nourish the young starting tubers. The decay of the tops indicate the maturity of the roots. The latter kinds often continue to grow till checked by autumn frosts. They should, however be dug before the ground is touched by frost at night.

Cutting the Sets.

This is one of the most important subjects to be considered in the propagation of Potatoes, and there is such a diversity of opinion regarding the manner and method of cutting, that many pages could be filled in giving the different experiences of the professors in this art. While we do not attempt to decide this question to the satisfaction of every one, we shall give our own views, and claim that in our method an enormous quantity of the tubers now annually planted may be thrown into the market, causing a reduction in the prices charged for this common and necessary crop. Without discussing the respective merits of planting whole Potatoes, or half-a-dozen pieces, each piece containing three or four eyes, in a hill, we shall state, what has been proven by so many cultivators, that two good eyes are ample for one hill, and the yield of large marketable Potatoes is larger than when more are planted. With the aid of the cut we trust our readers may be enabled to understand our method. Take any Potato and hold it before you, with the stem end (the place where it was joined to the stalk) down. It will then be noticed that the eyes are arranged around the tuber in regular ascending rotation from the bottom to the top, similar to the thread of a corkscrew, each eye being a little above and further round the side than the one next below it. Now take the Potato in the left hand, with the stem end down, keeping it in a perpendicular position throughout the entire cutting. Take a sharp, thin-bladed knife and remove the first eye, by placing the knife about equally distant between it and the eye next in rotation above it, sloping it to the indenture left by the stem (see dotted lines in centre cut), removing the flesh with it. When the first eye is removed, turn the Potato around in the hand until the next eye above appears. Remove this one in the same manner, and keep on turning the Potato, removing each eye as it appears in exact rotation, always sloping the knife to the stem. After three or four eyes are thus removed, the bottom part of the tuber will have a somewhat pyramidal form (see centre cut). It will be noticed that each eye removed has a similar form to that represented by the cut on the left, and has its proportionate share of the flesh attached. After the first two eyes are removed no further trouble will be found until the seed end is reached, and only a little extra care will be required to remove these closely clustered eyes. The cut on the right represents what remains of the Potato after all but the small eyes are removed, while the dotted lines show how to separate each of these. It will be noticed that the base retains the same form throughout, and by sloping the knife each time, and cutting down to the apex of this inverted pyramid (which is the centre of the tuber), each eye will be supported by an equal amount of the flesh which is to start it into a strong, healthy growth. With common varieties, where seed is cheap, many will think this manner of cutting too troublesome. But if every cultivator should save one-half his seed, as he easily could do (for it will only require two barrels of sets for an acre, instead of four, as is usually planted, the increase being equal), thousands of bushels would annually be saved. But to those who wish to obtain a large increase from a small quantity of seed, as is necessary to those who buy the new and valuable varieties, this manner of cutting so that every eye is saved will prove invaluable.

How to Raise Potatoes from Cuttings.

For this purpose any ordinary hotbed may be used. About the 1st of March take the Potatoes to be propagated, dividing them lengthwise, and laying these pieces with the cut side down upon the soil of the hotbed. Keep them perfectly dry until the top part has healed over and the sprouts have commenced to start. When the sprouts reach the height of 3 or 4 inches, cut them off about half-an-inch above the eye, and insert the ends of the cuttings thus obtained into the soil of the hotbed. Shade them from the sun, and water carefully until they are well rooted and the leaves begin to develop. The old pieces of the Potato will continue to throw up shoots to an almost incredible number, and these are all to be removed, as soon as strong enough, in the same manner as the first ones. In order to increase the crop still more, as soon as these cuttings have reached the height of 8 inches, their tops may also be removed, and planted in the same manner as

the slips from the Potato. As soon as the ground becomes warm and can be worked, prepare it as is usual in planting the tubers, and set out these young plants. It is best to transplant them on some cloudy day or towards evening, as the hot sun withers them and destroys many if planted in the hot part of the day. These plants will be found to grow very rapidly, and can be propagated indefinitely from cuttings of the older plants. No cuttings should be taken after the first of August, as they are liable to be destroyed by the cold weather before the crop is matured. The immense increase of stock by the use of this method may be illustrated as follows: a pound usually contains four medium-sized Potatoes, and there are from twelve to twenty eyes on each tuber. When cut and sprouted they will give, at least, five hundred plants. From each of these plants three cuttings may be taken, which gives a total of two thousand plants to be set in the ground. With the ordinary yield, each hill, at the lowest estimate, would give one-and-a-half pounds, or three thousand pounds; in all making about eighteen barrels of good, sound Potatoes, or a year's supply for a large family. We do not claim that this is either profitable or advisable with the common sorts of Potatoes; but with the many new and high-priced varieties which are now being disseminated at the prices of one, two, or three dollars a pound, it is almost invaluable, as for a slight expenditure a large stock may be obtained, paying to the propagator a thousand-fold. This is no new experiment, but has been practised by the initiated for the last few years, and has ever

Economical mode of cutting Potato sets.

proved a success. It is not confined to hotbeds, but many of our most prominent nurserymen have devoted whole greenhouses to this use, and we would confidently recommend it to our readers.

Two Crops a Year.

Take good sound early Potatoes, and cut them into single eyes, as is shown in the article on cutting. Allow these pieces to dry for a day or two, and then plant as early as the ground can be worked (a slight frost will not injure the Potato after being well planted). With ordinarily favourable weather the new crop of tubers will mature in from eight to ten weeks. As soon as they are ripe, dig them, and, after remaining a day or two in some dry and warm place, proceed to cut them into single eyes, as before. Place the pieces thus obtained into pans or boxes containing dry plaster or gypsum. This absorbs the abundant moisture, which would otherwise greatly check the growth, if it did not destroy the sets entirely. Allow them to remain in the plaster for ten or twelve days, or until the eyes commence to start, when they are to be taken out and planted as before. In the latitude of New York this is only applicable to new varieties, like the famous Early Rose or Extra Early Vermont, which are of a quick growth and early maturity; but, in many parts of the South, where the growing season is

long, it may be practised indiscriminately upon all varieties. A gentleman has raised two crops of Early Rose, a short time since in this vicinity, the two crops yielding an aggregate weight of 2,500 lbs. He planted his pound, cut into single eyes, early in March, and dug his first crop about the middle of May. These were then treated as above described, and planted on the 10th of June, and the second crop dug the 1st of September. The yield from the one pound at the first digging was 50 lbs.; and the second crop of this increase was 2,500 lbs., or over forty bushels. This method is within the reach of all, and there is no extra expense incurred for hotbed sashes, or any other forcing requisites.

How to Raise Seedlings.

Save any well-ripened seed-balls from a good variety, and plant in early spring in well-drained boxes of sandy loam. Sow the seed on the surface, and sift fine soil over them to the depth of one-quarter to one-half an inch; water sparingly, and, when the seedlings are 3 inches high, remove them from the seed-box without disturbing the earth around them more than is necessary, and plant in more roomy quarters. Many successful growers, however, prefer sowing the seed in open ground, when a partially shaded spot may be selected, and the seeds may be sown in drills about 10 inches apart; cover with half-an-inch of soil. When the plants are strong enough, thin out or transplant, and keep down the weeds until the tubers ripen. Some few strong-growing varieties will form tubers weighing from 6 to 8 oz. the first year. As a general rule they will be about the size of a Walnut. Store the tubers carefully until the next season, keeping them as cool as may be without freezing, when they may be planted in the same manner as any mature Potato. It usually takes three years to ascertain the true value of a seedling, and if a person is favoured by finding one really good variety among the many seedlings, he may feel well repaid for his time and trouble. Many new varieties are raised by hybridisation, which is a more difficult method, although it generally secures a greater number of good varieties. The manner of procedure is as follows:—Remove all flowers excepting those you wish to hybridise, then with a pair of sharp scissors remove all the anthers from the stamens in the flowers to be impregnated, just before they commence to discharge their pollen. When the flowers are dry, shake the flower containing the stamens of the variety which you wish to cross with it, being careful to do it when they are ready to discharge their pollen. Fit a piece of fine netting over the impregnated flower, to prevent the bee and other insects from leaving the pollen of other varieties upon the exposed pistil. The covering may be removed after two or three days. Do not disturb them again until the seed-ball has become well ripened, when the treatment as given in the first part of this article may be applied. Instances have been known, though rare, where one Potato would produce two distinct sorts from its different buds or eyes. The white Peachblow, for example, has been found growing on the same stalk with the Jersey Peachblow. As so much interest is now excited in the growth and propagation of new seedlings, and many of the new varieties command such high prices—it behoves our cultivators and amateur gardeners to avail themselves of the latest and, by actual tests, the best method of producing new varieties.

How to Store and Keep.

It is a matter of no small importance to the cultivator to be able to keep his crop of Potatoes in good condition through our long winters, and to present them for sale, free from blemish or mildew, in the spring. A well kept Potato brings three or four times its value in the market in early spring than the same stock will, if sold in the fall, paying an extra profit over and above the cost of storing, handling and care required. Of the three methods of storing in general use each has its champions. They are—storing in barrels, bins, or heaps or pits. The advantage of placing in barrels is, they can be easily handled, do not suffer from abrasion, can be readily looked over, and if disease presents itself it can be checked or removed. When thousands of bushels are raised on one farm, this method cannot be followed on account of the time and expense involved. Bins are largely used by our fore-handed

cultivators, especially those near large cities, as the tubers can at any time be reached and got ready for market. A dry, cool, well-ventilated cellar, with the light excluded, is the best place to store Potatoes. It has been found very advantageous in preventing decay to sprinkle lime in the barrels or bin at the rate, say, of one pound to each barrel. It acts as an absorbent and neutralises the earthy odours, thus directly acting as a preventive of decay to the tubers. The importance of excluding light from Potatoes, and keeping them as cool as possible, cannot be overestimated as means of preserving the crop.

A CUCUMBER MONSTROSITY.

I HAVE sent you a small fruit of Rollisson's Telegraph Cucumber, which has produced an entire leaf almost at its extremity. The plant which has borne this fruit was struck from a cutting in August last, along with others of the same variety, all of which have fruited

regularly throughout the winter, and are even now bearing freely. I never remember having seen such a case before. A. PETTIGREW.

The Gardens, Cardiff Castle, Cardiff.

[By carefully examining the accompanying illustration, which represents this monstrosity, the leaf-stalk will be seen adhering to the side of the Cucumber nearly to the top, where they separate. Such adhesions in the case of young and tender surfaces are by no means uncommon, though none exactly resembling that illustrated has ever before come under our notice.]

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The "Sweet" Capsicum.—Pimentos dulcis is the Capsicum grossum (Wildenow) var. monstrosus, and is the sweetest and largest-fruited Capsicum in cultivation. It requires plenty of heat and water, and may be had from the principal seedsmen both in England and France.—INTERNATIONAL.

Rhubarb Grown in the Dark.—The best-flavoured Rhubarb is got in early spring from the open quarters by putting boxes or large garden pots on the plants and covering them up with litter. The sorts I grow for this purpose are Baldry's Scarlet Prolific and Dancer's Early Scarlet. Both these varieties furnish very delicate crisp stalks, and the flavour is far better than when grown in the light.—WILLIAM TILLERY, *Welbeck.*

The Seville Long-pod Bean.—In addition to what was stated (p. 210) allow me to say that it grows to a height of a little over 3 feet. Its leaves are golden-green, and it produces pods some 7 or 8 inches in length and about half-an-inch in width. Each pod contains on an average five or six Beans, which are of a handsome yellow colour, slightly tinged with brown; in shape, they are long rather than large. It is considered of much value as a new vegetable.—V.

Osborn's New Forcing Dwarf French Bean.—After repeated trials in forcing this Bean, together with many other varieties in 1874, and also this season, I find Newington Wonder the only one that rivals it for earliness and good quality. This season I sowed them both on the 27th of January, and gathered the first dish of Beans from Osborn's in forty days and Newington Wonder in forty-two days, the former being most prolific and of the finest quality, either under glass or out-of-doors.—J. NISBET, *Awarby Park.*

Potato Planting Implement.—A correspondent of the "Cultivator" says that he has used one of True's Potato planters for planting his crop of 1874, and considers it one of the greatest labour-saving implements now in use. "It makes the furrow, cuts and drops the Potato, or drops it without cutting, as desired, in drills 18 inches apart, or in hills 3 feet apart, drops the fertiliser, and covers at the same time—doing the work of from twenty to twenty-five men in one day. In experiments made thus far, it has proved a perfect success, and withal a perfect revolution in raising Potatoes. I cannot grow Potatoes cheap without it—with it I can raise them and get them to market for less money than any other crop." Such implements should be worth a trial here.

Dwarf Brussels Sprouts Better than Tall ones.—The past severe weather has proved to one's satisfaction that those hardy kinds of Brussels Sprouts, such as Mein's Victoria and Dalkeith, are valuable vegetables at this season. No degree of cold seems to injure them, and although some seem to prefer a long shrivelled plant, by sowing and planting early, yet I prefer a plant 15 or 18 inches high, and one clothed from bottom to top with buttons. The frost and snow have hardened these, so that when boiled they are as fine as Marrow-fat Peas. It behoves gardeners to plant more of this fine hardy vegetable than is usually done, in order to meet a want much felt at this season after a severe winter. Seed sown in March, and again in the beginning of May, will furnish a supply from October till April.—CHEVALIER.

THE AMATEUR'S GARDEN.

Fruit Garden and Orchard.—The planting of all kinds of fruit trees should by this time be finished, and all recently transplanted trees should be well mulched with littery manure, to prevent undue evaporation from the soil surrounding the roots. All such trees should also be carefully examined, and, if found necessary, should be securely staked. Apple and Pear trees, &c., which may have been headed down, with the view of being re-grafted with improved sorts, may now have that operation performed upon them. All pruning and nailing of fruit trees on walls should now be finished, and protection, in some form, must be given to the bloom, more particularly to that of the Apricot. This protection is accomplished in various ways, and with varying success; but a temporary glass covering is undoubtedly the best. Failing this, however, recourse must be had to such materials as Haythorn's netting, Tiffany, old fishing nets, straw or hay-bands, Fern fronds, Spruce branches, or similar material. Bush fruit of all kinds will by this have been pruned; and the soil may now be slightly pointed, or forked over. As deep digging near to the roots of such plants should be avoided, to prevent as far as possible the ravages of the Gooseberry caterpillar, all round the stems of the bushes should have a good dressing of gas lime; or a thick layer of tan, fresh from the tan-yard, should be applied and allowed to remain throughout the season. Fig trees which may have been unnailed from walls, or other positions, with the view of being protected from frost by means of dry litter, mats, &c., should now be uncovered, and should receive the necessary pruning, and be again nailed in. Fill up blanks, if any, in plantations of Strawberries, and point over the surface of the soil, between the rows, to destroy small weeds, and to offer a somewhat loose surface for early runners (which may be required for forcing) to root into.

Kitchen Garden.—No time must now be lost in getting in the necessary crops; but, except in favourable seasons, little advantage is gained by sowing seeds or planting tubers very early. On examining some Potatoes the other day that were planted early in February, they were found to have made no progress whatever, and, to all appearance, will not be more forward than others of the same kind that were planted a month later. The principal crop, however, of this useful esculent, if not already planted, should now have immediate attention. Late planting, in the case of the Potato, whatever the sort may be, cannot be recommended, as, when disease makes its appearance, it generally attacks all, in whatever stage of growth they may happen to be in; and if the tubers are in a tolerably advanced condition, the crop consequently suffers less injury. Established beds of Asparagus should now have a portion of the surface-soil removed into the alleys, where it should be dug in, while the surface of the beds themselves should have fresh soil, a dressing which should be followed by a liberal application of salt. Besides being a suitable manure for Asparagus, salt also, to some extent, prevents the growth of weeds, and destroys or drives away slugs and other depredators. Where fresh plantations of this esculent are intended to be made, the beds for the reception of the roots should by this time have been duly prepared, and the planting should be done as soon as the plants have commenced to grow, or when they have made shoots of about an inch in length. Plants one year old are generally found to be best for this purpose, and one-year-old plants of the variety known as Conover's Colossal will be found to be in all respects equal to two-year-old plants of the common kind. Some prefer sowing seeds upon the prepared beds at once, and afterwards thinning out the plants to the proper distances apart, which should be 18 inches. Remove the littery matter which may have been placed around the stools of Globe Artichokes for protection, and thin out the offsets, or suckers, which may be used, if required, to form fresh plantations. Jerusalem Artichokes should also be planted now, and, as these attain a considerable altitude, they should be planted in lines not less than 6 feet apart. They will grow and succeed well in almost any kind of soil, and are sometimes found useful during the summer for concealing unsightly objects. The principal crop of Broad Beans should now be sown to succeed the first crop, which will possibly be the early Green Mazagan. This should be succeeded by the Long-pod or the Green Windsor. In small gardens some of the dwarf sorts are also very suitable. Continue to make sowings of the various kinds of Marrow Peas. The tall-growing sorts are most productive, but the dwarfs, or sorts which grow from 3 to 4 feet in height, are the best suited for small gardens. There are now in cultivation so many excellent varieties of this delicious vegetable, old as well as new, that it would be invidious to name any particular sorts; to make sure, however, of really good crops on light land, during dry seasons, it is advisable to sow in trenches, as if for Celery, at the distance of 6 feet from row to row; or, the Pea crop may, with advantage, be made to follow Celery. Sow in the same position the Celery occupied; and whatever goodness the latter may

have left in the trenches will be sure to be sucked up by the Peas; and round Spinach should be sown between the rows. Parsnips should have been sown in February; as should also have been Parsley, the seed of which is somewhat slow to vegetate; but if not already sown these should be at once attended to. Cauliflowers should be sown in a slight hotbed, to succeed the autumn-sown plants. Leeks, Brussels Sprouts, and the various kinds of Kale, should have been sown early in the present month; while the various sorts of Broccoli should be sown now, together with Savoy and Cabbages, &c. Plants of the latter, from beds sown last August, should now be planted out, as should also Cauliflower plants from hand-glasses or frames, or from sheltered positions under walls. The first crop of Early Horn Carrots should be sown in a frame on a slight hotbed early in February, and a bed of the same sort should be sown on a warm border about the first week of the present month. The general or principal crop (which may consist of the Altringham, Red Surrey, or Long Orange sorts) may be sown now, should the soil be found to be in good order for its reception, or it may be deferred until the beginning of next month. There is an old saying with regard to the early crop of Turnips, viz., that they will be sure to bolt or run to seed if sown before Lady Day; a small sowing, however, of the Early Stone variety may be made now upon a warm border facing the south. Also a good breadth of the White Turnip Radish, and when these become too large to be used as salad, they will be found to be a good substitute for young Turnips. The principal crop of Onions if not already sown, should be got in now; and, where Potato-Onions are grown, they should now be planted, together with Shallots and Garlic, should these not have been planted in October. Continue to transplant autumn-sown Cos Lettuce, and to prick out, in a sheltered position, or in a frame, young plants of the summer sorts which had been sown in heat in February; commence, too, to sow, on a warm border for summer use, the Paris green and the Paris white Cos varieties, as well as some of the many Cabbage sorts. Attend to the blanching of Seakale, and take care to prevent the material with which the pots are covered from becoming too warm. For this purpose tree-leaves are possibly best suited; but stable manure of any kind will answer the same purpose. Make fresh plantations, if required, selecting for the purpose good and richly-manured soil; and seedling plants one year old are to be preferred to older kinds. If the Cucumber-bed is in proper condition, the plants may now be put out, if this has not been already done. Unless it be in gardens where the necessary appliances of pipes and hot-water tanks for bottom-heat are in existence, it is more economical to purchase plants fit to plant out at once, than to attempt to raise them so early in the season; but, as the pit or frame will now be fairly at work, Melon seeds may be sown, if desired for an early crop. A small sowing of white Celery would probably be made in heat, during February, for early use; and such plants may now be sufficiently forward to be pricked into seed-pans or boxes, or they may be potted singly into small pots, and gradually hardened off. The present is also a suitable time to make the principal sowing, in a gentle warmth; the Sandringham White and the Leicester Red are two of the best sorts. Tomatoes, Capsicums, Sweet Basil, Sweet Marjoram, Ridge Cucumbers, Vegetable Marrows, &c., may be sown now in gentle heat. It is quite unnecessary to sow such things earlier than about the present time, as they cannot be planted out earlier than the end of May, and they are by no means benefited by long retention in pots.

Pleasure Ground and Flower Garden.—Attend carefully to lawns and Grass belts, &c., extracting all such broad-leaved plants as the Plantain, Dandelion, &c.; and soon after rainfall, or when the turf is in a soft, spongy condition, let all be well rolled with a heavy iron roller. Wherever it may be found necessary, Laurels and other evergreen shrubs and trees may now be pruned. This pruning should consist of using the necessary means to keep the various plants in proper form, &c., by stopping or removing, in the case of Coniferous and other trees, rival leaders, and in preventing the more delicate or dwarf-growing varieties from being injured or smothered by stronger-growing sorts. Spring flowering plants and bulbs, occupying beds in the flower garden, will, in many instances, be in full flower, and should have every necessary attention; the turf, gravel walks, &c., should also all be kept scrupulously clean, and should be frequently rolled. In some instances it is already necessary to commence mowing, and the margins of walks and borders should now be cut with the edging knife.

Forcing Houses and Vineries.—The fruit will now require to be thinned in the early house; the bunches must be carefully thinned in the first instance, and care taken to avoid a too heavy crop remaining upon the Vines, more particularly if they are not in a strong and vigorous condition. In selecting the bunches to be retained endeavour, so far as possible, to leave them at such distances from each other as to give a regular

and uniform appearance to the crop, but in no instance should more than one bunch be left upon a spur; and the spur or shoot should also be stopped at the first or second joint beyond the branch. The berries of each bunch should also be carefully thinned out, having reference to the particular kinds in question, and to the size such berries are likely to attain. Handling the fruit more than is really necessary must be avoided. Watch carefully for any indications of mildew; and, if any such appear, have recourse at once to sulphur in some of its forms. Ewing's Infallible Composition is a certain and easily applied remedy. Although the weather has, to all appearances been anything but favourable for the setting of early forced fruit, Peaches and Nectarines have set in great abundance, and will require immediate attention in thinning out, and, to keep the trees in a clean and healthy condition, the syringe must be freely used upon them. Straw-berries in pots, which have been gently forced, will now be getting ripe, syringing must be discontinued, manure-water must be withheld, and the ripening fruit must be supported with a stake, to prevent it coming in contact with the soil. In orchard-houses the Apricot trees will still be in full flower, and should be kept as dry as possible, and during very cold nights, such as we are occasionally experiencing, might, for greater safety, have a piece of Tiffany thrown lightly over them; but, when there is no apparent danger from frost, the ventilators may, to some extent, be open by night as well as day. Peaches, Nectarines, Cherries, &c., are also in bloom in these structures, and should have abundance of air whenever the weather is sufficiently mild, and, as soon as the fruit is fairly set, the syringe, or the more powerful garden-engine, must be used vigorously, to keep them free from insects of all kinds, and, if this cannot be accomplished by this means, recourse must be had to fumigation, as aphids and red spider must necessarily be subdued, at whatever cost.—PETER GRIEVE.

ORIGIN OF BRAZIL AND SAPUCAYA NUTS.

THE particular tree which yields the Brazil Nuts is separated by Mr. Miers from the older species of *Bonpland*, *Bertholletia excelsa*, under the name of *B. nobilis*, distinguished by its loftier growth, its immense trunk bare to a great height, stouter branches, leaves of a more rufescent hue, with more numerous closer nerves, more reticulated, or much shorter petioles; in its broader panicle with several long branches spreading horizontally; and in the rounder and more entire lobes of the calyx. The quantity exported from Pará alone amounted in six months of the year 1833 to 18,862 alquieres, and from Manáos, on the Rio Negro, to 9,976 alquieres. This would correspond to an average annual export of $2\frac{1}{2}$ millions of the fruits, or 50 millions of the seeds, measuring about 60,000 bushels; and this does not include the large quantity exported from the Rio Orinoco, Demerara, Cayenne, Maranhao, and other places. Their value in Brazil is about 30s. per bushel. The hard fruits which fall to the ground are broken in the forest by Indians, where a man and a boy will break about 300 of them daily. The kernels of these Nuts, broken in a similar manner, are subjected to pressure, when they yield an oil greatly esteemed for domestic purposes and for export, each pound of the kernels yielding 9 ounces of the oil, valued at 2s. per lb. This oil consists, according to Martius, of 74 per cent. of elæine, and 26 per cent. of stearine. The finely laminated inner bark of the trunk is

also a valuable article of commerce, especially adapted for the caulking of ships and barges, being worth about 18s. per cwt. The tree is about 130 feet high, with a trunk 14 feet in diameter up to a height of 50 feet, and quite bare to the height of 100 feet; its leaves are from 10 to 15 inches long; the fruit globular and 6 to 6½ inches in diameter. The question naturally arises, How do the seeds germinate and strike root, confined as they are in the pyxidium as in an inextricable prison? It is evident that they cannot find an exit through the opercular opening; nor can they escape by any other means than the rotting on moist ground of the pericarp which is three-quarters of an inch thick. It probably requires three years' exposure to the sun and moisture before so thick a shell could decay sufficiently to allow of the liberation of the seeds, and then, perhaps, another year's exposure before the thick testa of the seeds could rot sufficiently to allow the embryo to germinate. This shows an extraordinary power of vitality in the embryo, which seems to remain four or five years in a dormant state. Oily seeds are generally supposed to ferment and decay soon, but that is perhaps, Mr. Miers suggests, when the oil cells are contained in albumen; here, however, we find a reverse condition. It is stated that when an embryo of the *Bertholletia* is extricated and planted under the most favourable circumstances, it takes a whole year before it begins to germinate; this may possibly be due to the large amount of stearine in the oil-cells, which, in a great measure, preserves it from decay. The tree which yields the Sapucaya Nuts of commerce is separated by Mr. Miers from *Lecythis ollaria* of Linnæus, and *L. zapucaya* of Aulet, and named *Lecythis usitata*.

The Fever Gum Tree (*Eucalyptus globulus*).

THE FEVER GUM TREE.

THE accompanying illustration represents a young tree of *Eucalyptus globulus* or Fever Gum tree, a species about which much has lately been written. Both in Tasmania and Australia this Gum tree grows with wonderful rapidity. In the former colony specimens of it often attain a height of 300 feet, whilst trees of it from 200 to 250 feet are comparatively common. The Australian colonists distinguish many of the trees of this genus by characters derived from the bark; some having smooth, others rough or cracked bark; some are solid (Iron-bark), while others are fibrous (Stringy-bark); and, finally, in some species the bark scales off in flakes, either from the whole tree or from the upper part only. They are also called Gum trees, in consequence of the quantity of gum that exudes from their trunks. The timber is exceedingly valuable, and is in common use in our Australian and Tasmanian colonies. In the latter, the three following species yield the best quality of timber, namely:—*E. globulus*, the Blue Gum; *E. gigantea*, the Stringy-bark; and *E. amygdalina*, the Peppermint tree. But of these the first-mentioned is considered the most valuable, although the Stringy-bark attains the largest size. *E. globulus*, we fear, will not withstand exceptionally severe winters, even in the most southern parts of England; but its beauty when young, both as regards foliage and habit of growth, renders it well worth a place in our gardens. It is easily obtained, grows rapidly, and, if cut down at any time by frost, can readily be renewed. Sixty plants of it, planted at Chiswick in 1847, grew rapidly, and were uninjured by the winters of 1847-8 and 1848-9, but were destroyed by a severe frost in January, 1850.

DEW AND MOISTURE IN THE AIR.

THE moisture always present in the atmosphere is to be traced to evaporation by which liquid water is changed into an invisible vapour. The rapidity with which evaporation occurs depends upon a number of circumstances. Since at all temperatures lower than the boiling point of a liquid its vapour escapes from the upper surface only, the greater the extent of this surface, the more rapid the evaporation. Then, again, the higher the temperature of the liquid, the greater its repulsive power, and, consequently, the more energetic its evaporation. The pressure of the atmosphere upon a liquid surface must also, as already explained, effect the formation of vapour; the less this pressure, the more rapid the evolution of vapour. All liquids capable of forming vapour at ordinary temperatures, vapourise almost instantly in a vacuum. The capacity of the air for moisture, however, is limited, and when as much vapour has passed into the air as it is capable of holding or, in other words, when it is saturated, all evaporation ceases. The quantity of moisture already present in the air will then necessarily affect the rapidity of evaporation. Renewal of the air is also favourable, since, when no wind is stirring, the lower strata become saturated with moisture, and then all further evaporation ceases until the excess is distributed through the upper and dryer layers by gradual diffusion. The capacity of the air for moisture increases very rapidly with the temperature. The following table gives the weight in grains of the aqueous vapour contained in a cubic foot of saturated air at different temperatures, according to a writer in the "Exchange and Review."

° Fah.	Grains.	° Fah.	Grains.	° Fah.	Grains.	° Fah.	Grains.
0	0.545	30	1.969	60	5.765	90	14.810
10	0.841	40	2.862	70	7.992	100	19.790
20	1.298	50	4.089	80	10.949	109	25.429

Silliman gives the following law:—"For every 27° temperature above 32° the capacity of the air for moisture is doubled." For example:—A body of air, when saturated, contains, at 32°, the 160th part of its own weight of vapour; at 59°, the 80th part; at 86°, the 40th part; at 113°, the 20th part;—or, in other words, as the temperature increases in an arithmetical series, the capacity for moisture increases in a geometrical series. We distinguish between the absolute and the relative humidity of the atmosphere. By the absolute humidity, we understand the quantity of vapour actually present, irrespective of temperature; by the relative humidity, the quantity present, as compared with that required to completely saturate the air. Thus, suppose the air, when at the temperature of 80°, contains but 5.475 grains of moisture—since at this temperature it is capable of holding twice as much, or 10.949 grains—we say that its relative humidity is 50 per cent., or half. If, now, the temperature of the air be increased to 100°, without the addition of any more vapour, then the relative humidity becomes 25 per cent., or one-fourth; since at this temperature the air would hold, if saturated, nearly four times the amount it actually contains. Should, however, the temperature be lowered, the relative humidity increases, until at last the air becomes saturated, and condensation begins, which, as the foregoing figures show, would be nearly at 60°. In general, any temperature at which saturation is reached is called the dew point, which, for air containing 5.765 grains, is exactly at 60°; for air containing 19.790 grains, is at 100°. As a rule, the air over the ocean is always very near its point of saturation; that over the continents, on the contrary, contains, on an average, but three-fifths of the moisture it would hold if saturated. By the incessant action of the winds, and the diffusion of gases, the excess of vapour over the ocean is continually being distributed over the surface of the continents. By these means we generally find that the total quantity of moisture decreases from the coasts of the continents towards the interior; it also decreases from the equator towards the poles, on account of the decrease of temperature. Peculiarities of surface and situation produce great differences in the quantity of vapour generally present in the air above any given place. Thus, Great Britain, bathed by the moist, warm air of the Gulf Stream, has its atmosphere generally near the point of saturation, while the arid steppes of the great Mongolian Plateau, in Central Asia, hemmed in by the huge marginal mountains, is swept by thirsty winds that hold but 15 to 20 per cent. of the vapour they could hold if saturated. Having thus briefly discussed the preliminary principles which regulate the quantity of moisture in the air, we are now in a position to readily understand the manner in which the invisible vapour becomes visible. We name collectively, precipitations, any of the various forms in which the moisture is condensed; for example—mist, fog, cloud, dew, frost, rain, snow, or hail. Now it is evident that whenever the air is cooled below the temperature of its dew point, the moisture it can no longer hold must become visible in one or the other of these forms of precipitation. The particular shape assumed by the condensed vapour depends upon peculiarities of cooling, the amount of reduction of temperature, and the absolute humidity of the air previous to its cooling. It is our object in the present article to consider that

peculiar form of deposition known as dew. When the air is very near the point of saturation, a slight reduction of temperature will occasion the deposition of its moisture. Ice water, or cold spring water, poured into a vessel, will so chill the air that comes in contact with the outside as to cause it to deposit its moisture. Such is the origin of the minute drops that almost immediately collect on the outside of vessels containing cold water. The phenomena of dew is of an exactly similar nature; the moisture of the air being condensed by the reduction of temperature, which is caused by the cold objects on the surface of the earth. Let us examine carefully the manner in which this reduction is produced. The law of the reduction of temperature of the air, with the increase of distance from the earth's surface, is only generally true during the daytime. At night—especially when the sky is free from clouds, and the preceding day has been moderately warm—the air at a short distance above the ground will be considerably warmer than that in almost immediate contact with it. Of two exactly similar thermometers—one placed on a bed of leaves, or some other non-conducting substance, and the other suspended a short distance above the ground, the former will mark the lower temperature; the leaves radiating their heat into space, cool the air near them considerably lower than the stratum in which the upper thermometer is suspended. Radiation into a cloudless sky will often cool the air near the surface from 6° to 10° below the temperature of the upper layers.

The formation of Dew.

The cause of the formation of dew is simple. During a moderately warm day in autumn the air becomes heavily charged with moisture; at night, the objects on the surface of the earth, radiating their heat into the air, soon acquire a temperature considerably lower than the air. When, then, the air comes in contact with these colder objects, its temperature is lowered, and if the reduction be continued below the dew point, the moisture will be deposited as dew on the objects causing the chilling. The foregoing theory of dew was propounded by Dr. Wells, of London, who was born in South Carolina. Though seemingly simple, now that the true explanation has been out, it was only discovered by Wells, in all its completeness, after long years of patient and continuous study; indeed, it may even be said that the discoverer gave his life as the price of his discovery, since frequent exposure to the chilly air brought on a series of colds that resulted in his early death. It cannot have escaped the notice of all gifted with but ordinary powers of observation, that the amount of dew found in the mornings on different objects varies considerably. The vegetation, for example, will often be drenched with it, while the road bed, the bare rocks, or soil, contain little or none. Differences, too, are observable in the amount found on particular kinds of vegetation; shrubs, trees, and Grasses having received varying quantities. These differences are to be ascribed to the varying rapidity with which objects lose their heat by radiation, and, consequently, in the degree to which they reduce the temperature of the air. Dr. Lardner suggests a very beautiful experiment, which may well repay our readers to repeat for themselves, with such modifications as circumstances may require. Place a clean glass cup in a bright silver basin (a tin one will answer all purposes), and expose both to the air overnight, during the season of the year that dew is deposited. In the morning the glass vessel will be covered with dew, while the metallic basin will contain none whatever. If, now, the experiment be repeated, and a silver mug be placed in a glass basin, and exposed to the air, the basin will be found covered with dew, while the cup will be free. The explanation is simple. Of the two substances—the glass and the metal—the former is much the better radiator of heat; hence, its temperature being colder than that of the metal, the dew is deposited on it in preference. It is a general law that, as regards the surface action of matter, bodies that are good absorbers of heat are almost equally good radiators—the same peculiarity of surface that allows the heat to enter the mass of the substance, allowing it equally well to pass out again by radiation. That condition of surface, however, which favours the reflection of heat, must necessarily be opposed to radiation, since the heat being reflected is not able to enter the body. The metals, as a class, are all good reflectors, especially when polished, and are consequently poor radiators. But a small amount of dew should therefore be deposited on them, as compared with that found on other objects. The deposition of dew becomes, then, a kind of natural thermometer, enabling us to see, from the quantity found on different objects, the relative reduction of temperature they have attained through radiation. But it may sometimes be remarked that of two different pieces of the same substance placed near each other, one contains a larger proportion of dew than does the other. A close inspection will generally show that one of them is separated from the ground by some good non-conductor, while the other is in direct connection with it. So circum-

stanced, although their radiating powers be exactly the same, the first must soon grow colder than the second, since it has only its own heat to lose, while the other is continually receiving additional heat from the ground. To the occasional bedding of ashes on which some streets and pavements are laid, in default of the more substantial gravel, must be attributed the greater deposit of dew in some streets than in others, or even occasionally on particular stones in the same street. A much greater quantity of dew is deposited in clear nights than when the sky is covered with clouds. On cloudless nights, nothing exists to check free radiation into space; objects, therefore, become considerably colder than the surrounding air, and thus produce a much greater reduction of its temperature, and receive a correspondingly heavier deposit of dew. When, on the contrary, the sky is overcast, the heat radiated from the objects striking the clouds is reflected from them back again to the objects, thus raising their temperature. This is the popular explanation. To be more precise, the clouds radiate their heat to the earth as well as reflect the terrestrial radiation, and by this mutual exchange of heat the reduction of temperature is considerably lessened. With a cloudless sky, the heat of the ground is so much higher than that of celestial space, that the radiation therefrom to the ground is almost inappreciable. Considerable differences in the amount of the deposition are observable between night when a strong wind is blowing and when it is entirely absent; a greater quantity is always found after a calm night than after a windy one. Although terrestrial objects may lose their heat by radiation, the air does not remain in contact with them long enough to suffer any very appreciable reduction of temperature; on the contrary, on a calm night, copious deposits are possible, since the air has an abundance of time to lose its heat. Between perfectly calm nights and those during which gentle breezes are stirring, the maximum deposition occurs in the latter, since, when the air is perfectly still, no cause exists to renew the air, and when the comparatively thin stratum in the immediate neighbourhood of the object has deposited its moisture, all further deposition ceases. More dew falls in the suburbs or in the open country than in the heart of a city, since in the latter, although the objects in the street lose their heat by radiation, a marked reduction of temperature is prevented by radiation from the walls of the neighbouring houses. On the house tops, this retarding influence of mutual radiation is diminished, and about the same quantity falls as would at an equal elevation in the open country. On very clear nights, when the atmosphere during the day time has been very near its point of saturation, radiation may take place with such rapidity that a considerable depth of air may be reduced below the temperature of its dew point.

Dew resembling a gentle fall of Rain.

This is common in our latitude during many autumnal nights. Places situated near the sea have, of course, more dew than those in the interior of the continents. This is a necessary result of the greater evaporation that occurs over the ocean. Great Britain, as we have already mentioned, has, in general, a nearly saturated air. We find, accordingly, that its annual dewfall is unusually large; it amounts, on the average, to nearly 5 inches, which bears a sensible proportion to its entire rainfall. In the tropics, too, where evaporation reaches its maximum, very large depositions of dew occur. At times they resemble, in their intensity, the gentle showers of the temperate regions. Along the desert of Atacama, on the western coast of Peru, is a strip of land where rain never falls. The absolute sterility which would thereby be occasioned is somewhat mitigated by the dew that often descends in large quantities. Further to the north and south, along the coast where the sterility is not so marked, the dew supplies very well the place of rain. When the temperature of terrestrial objects has been lowered by radiation below the freezing point, the moisture is deposited in the form of ice, and is then known as frost. It has often been a matter for surprise to some that frost is frequently found when the temperature of the air, as indicated by a thermometer hung some little distance above the ground, is appreciably higher than the freezing point. This will be understood when it is remembered that it is only the air in immediate contact with terrestrial objects that had its temperature sensibly affected by their radiation, and that, therefore, the layers of air quite near the surface, may have a temperature considerably lower than the freezing point. Indeed, frost may often be noticed in the morning, when the temperature of the air, as marked by a self-registering thermometer, has not fallen throughout the night nearer the freezing point than 5° or 6° . In such instances we will generally find that the objects on which the frost appears are not only good radiators, but, as well, poor conductors, or at least rest upon good non-conductors. For example, rough boards are frequently covered with frost, when other objects are comparatively free from it. They owe their greater reduction of temperature to their good

radiating and non-conducting powers. Generally, when frost occurs, the temperature of the objects does not fall very appreciably below 32° ; so that but slight coverings will protect plants during the cool autumnal evenings. Coarse straw matting loosely wrapped around the plant, or even if stretched awning-like over it, will effectually prevent any serious effects of frost. This protection is clearly not to be ascribed to any non-conducting power of the matting, but rather to the obstacle it offers to the rapid loss of heat in the plant by radiation. Its effect is precisely similar to the action of the clouds in preventing a considerable deposition of dew.

Frost on Windows.

An excellent illustration of the deposition of frost may be obtained from the frozen moisture so commonly found on the inner surface of the panes of glass in bedroom windows, when the temperature of the outer air is lower than 32° . The cause, of course, is to be attributed to the cooling of the air in the room by the colder air outside. Now, an exceedingly neat experiment may be made, with but little trouble, by which the effect of radiation on the deposition of frost can be studied. Cut out two small pieces of tin-foil, and fix one on the inside of the window and the other on the outside, observing to place them on different parts of the pane, so that they may not face each other. In the morning it will be observed that the deposit of frost is appreciably thicker on the piece of tin-foil that is on the inner surface of the pane than on the rest of the window, while it is entirely wanting on that portion of the glass covered on the outside by the tin-foil. Clearly, therefore, the inner tin-foil must have made that part of the glass under it colder than the rest, and the outer foil the portion under it warmer. The explanation is as follows:—Tin-foil is a good reflector of heat, and, consequently, a poor radiator. The foil on the inner surface of the pane allows the glass beneath it to grow colder than the surrounding portions, by the protection it affords to the heating of the glass by radiation from the apartment, since it reflects nearly all the heat of the apartment that would otherwise have passed into the glass at this point. On the contrary, the foil on the outer surface of the glass prevents the radiant heat of the apartment from escaping through the glass at this point.

GARDENING FOR THE WEEK.

Trees and Shrubs.

PREPARATIONS should now be made for transplanting all kinds of evergreens, so as to be ready to commence operations the moment the cold drying March winds are over. Where there are large quantities to transplant, such things as Rhododendrons, Aucubas, Box, and others that always lift with good balls, may be commenced with at once with the greatest safety. This will allow more time and strength to be concentrated on others later on that do not transplant so well, and therefore require more attention. The ground should be trenched at least 2 feet deep before planting, if at all hard, unless the plants are to be placed at wide intervals apart, in which case large holes will suffice. These should be dug much larger and deeper than is necessary to receive the ball of the plant, so as to thoroughly break up the soil and allow the roots plenty of freedom. This is of the greatest importance to the future growth and well being of the plant, as it is impossible for it to make satisfactory progress if the soil immediately surrounding the roots is hard and impenetrable, or too stiff and retentive. In both cases, therefore, it is necessary that it should be thoroughly broken up so as to ensure rapid and satisfactory growth. Should the natural soil be at all poor, the plants will be much benefited by filling in the holes with fresh loam, such as may be obtained from an old bank or pasture. This will start them into free growth, and assist them materially in getting over the check incurred through removal. In covering the roots the soil should be well washed in among them as the operation proceeds by using plenty of water, which should be thrown in with considerable force. By so doing, any vacancy that may occur under the ball, or amongst the roots, will be filled up much better than can be accomplished by treading, and it is of the greatest importance that these cavities should be well filled up, so as to exclude air and get the soil settled and properly consolidated. In forming new shrubberies, the plants intended to be permanent should be placed at a sufficient distance apart to allow room for their proper development without unduly crowding each other. The distance necessary for this will, of course, depend on the kinds used, and the size which they are known to attain; but it may be roughly stated at from 20 to 30 feet. Shrubs of all kinds are too often mixed up indiscriminately, without regard to size, habit, or character. The proper way is to make a selection of the best and most ornamental, and fix on the sites, having due regard to their height, character, and general suitableness to the position which it is intended they should occupy. It is far better to have

fewer varieties than it is to have an heterogeneous mixture that does not associate in a pleasing and satisfactory way, and this seldom occurs if there are too many varieties mixed up together without some design and forethought as regards harmony and effect. Having arranged and planted the permanent plants at proper distances apart, the intervening spaces may be filled in with any of the common kind, and these can be removed, as occasion requires, to make room for such as are of more value. By planting in this way an immediate effect is produced; and it has the double advantage of affording a good supply of large plants to meet the various wants that occur from time to time in most places. The different kinds of resinous plants, except Larch, transplant better in April than any other time of the year. For ornamental purposes, to plant as single specimens, the following are the handsomest and most distinct:—*Picea nobilis*, *Nothmanniana*, *grandis* pinsapo, and *cephalonica*. The latter, on account of making its growth rather early, is occasionally injured by late spring frosts. To obviate this, it should, if possible, be planted where the morning sun does not reach it, as then the growth will be later, and the frost will pass off without any ill effects. Where the soil and situation suit it, this is one of the handsomest and most symmetrical of Conifers. The Douglas Fir (*Abies Douglasii*) should be planted extensively for timber; its growth is very rapid, and the wood heavy, solid, and very resinous, and there can be no doubt of its great value and lasting qualities. The Hemlock Spruce (*Abies canadensis*) is valuable as an ornamental tree, on account of its light silvery foliage and graceful pendulous habit, but it should be planted where its roots can find a good supply of moisture. Among Cypresses, *Cupressus Lawsoniana* and *Lambertiana* may be mentioned as fast growing distinct varieties that are sure to give satisfaction. *Sequoias sempervirens* and *Taxodium distichum* should be in every collection. Few deciduous trees equal the latter for ornamental purposes. In summer the leaves possess a peculiarly pleasing shade of green, and in autumn they are unsurpassed for the warmth and richness of their colouring. *Thuja borealis* and *dolabrata* are very desirable fast-growing plants, and exceedingly ornamental. Among *Thujas*, *Lobbii* and *gigantea* are the largest and most stately. The different forms of Variegated Yew (*Taxus*) are most valuable on account of their medium growth and rich colouring. When making their young wood in spring they present a striking appearance.

Ornamental Foliage and Flowering Shrubs.

As regards large or otherwise strikingly or namental foliage among shrubs, the following stand foremost in the rank, viz., *Aralia Sieboldi*, a plant that should be in every garden, being exceedingly ornamental, and having proved itself to be sufficiently hardy to stand very severe winters. It has rich, glossy, deeply-cut green leaves, much resembling those of the Fig in form, and is highly prized for sub-tropical work and indoor decoration in winter, and for halls, corridors, and such like places, it has few equals. *Berberis Bealii* and *nepalensis* are likewise valuable on account of their large, rich glaucous green leaves. *Bambusa gracilis*, too, is one of the most elegant plants which we possess, and is very suitable for the margins of ponds or for planting on sloping banks. *Osmanthus ilicifolius* and its variegated form, are likewise distinct and ornamental. *Eurya latifolia* variegata is said to be quite hardy; but it is so good for winter decoration indoors that I have not yet ventured it outside. Several of the *Euonymus* are deserving of pot culture for indoor decoration, and almost rival the *Crotons* for richness of foliage; and they are even more serviceable, on account of their hardiness. Among flowering shrubs, the following are sure to give satisfaction, viz., *Abutilon vitifolium*, with its fine Vine-shaped leaves and large Mallow-like flowers. It is, however, a little tender, and should be planted on sheltered situations. *Berberis Darwinii* and *stenophylla* are both gems, either to grow in the form of shrubs, or for covering low walls, being equally beautiful when in bloom, or laden with their rich metallic blue berries. *Arbutus Unedo* is a universal favourite, and one of the most useful and ornamental shrubs which we possess. The dry seasons have just suited this, as it has been laden with its beautiful Strawberry-like berries. *Rhus Cotinus*, with its lovely plumes of feathery-like inflorescence is also a charming plant that should have a place in every shrubbery. It should be placed in the full sun, or the plumes do not assume the rich tints of colour that add so much to their beauty. *Garrya elliptica* is another very ornamental evergreen, having flowers arranged in catkins, like those of the Hazel. These make their appearance in February. While the plant in its growth and foliage might be mistaken for the Evergreen Oak, like that tree it is very difficult to transplant, and should, therefore, be obtained in pots. For low south walls, *Ceanothus azureus* and *Escallonia macrantha* are two of the best shrubs we have. For the same situation, *Magnolia grandiflora*, with its noble foliage and highly-scented flowers, is a grand plant, where it has plenty of

room and a light dry soil in which to grow. In the south and south-west of England this succeeds well as a shrub on the open lawn; and at Kings Weston there used to be some noble specimens. The old double Furze (*Ulex*) is deserving of extensive planting, as it will succeed in poor soils where little else will grow; and, when in bloom, few things are more striking.—J. SHEPPARD, *Woolverstone Park*.

Flower Garden and Pleasure Grounds.

Look over all newly-planted trees and shrubs, as, in some instances, staking or treading in may be found to be necessary, where the plants may have become loosened through wind-moving; and, if the weather continue dry, copious waterings will also be necessary. In performing this operation a basin should be formed round the stem of each plant, in order to confine the water where it is required, and the sides of this basin should be levelled in as soon as the water given has disappeared, so that the dry soil may, as far as possible, prevent evaporation. Let lawns, grass belts, and verges be swept thoroughly clean, and afterwards repeatedly rolled with a heavy roller, while the turf is yet in a soft and somewhat spongy condition; for, if this is delayed until the weather sets in dry, the roller will make comparatively little impression upon it. Gravel walks should also be neatly edged and frequently rolled, as nothing tends more to give an appearance of finish and neatness to a garden than careful attention to this matter. Spring bedding plants will soon need attention; the beds and borders containing them should be kept scrupulously clean, and all their surroundings rendered as enjoyable as possible, as their season, it must be remembered, is necessarily somewhat restricted. The weather, too, has been hitherto so unfavourable for the early development of spring flowers that many of the finest will be later than usual in flowering this year. In the herbaceous ground the various varieties of Phlox and Pentstemon may now be planted out. Both these genera have, within the last few years, been so greatly improved that they are now well worthy of any extra care and protection which may be afforded them in winter, especially the Pentstemons, some of which are not altogether hardy. It is, therefore, advisable to insert cuttings of these plants early in autumn, under a hand-glass or in a frame, to pot them off as soon as they are well rooted, and to winter them in a cold pit, and plant them out in beds, or as single plants, on the herbaceous border about this time of year. Plants of the beautiful *Dielytra spectabilis*, and its white-flowered variety, although quite hardy, so long as they are in a state of rest, are, nevertheless, very liable to be disfigured by spring frosts, and should have a slight protection of some sort whenever there are indications of the thermometer falling below the freezing point. Continue to gradually harden off the various kinds of bedding plants, and, wherever the stock of any variety may be considered insufficient, let such be increased by means of cuttings as rapidly as possible. The various kinds of *Alternantheras* will now, if placed in a moderately high temperature and moist atmosphere, produce an abundant supply of cuttings, which will root freely in a mixture of sharp sand and finely-sifted leaf soil, in 6-inch or 8-inch pots, which should be placed under hand-glasses, or in a close propagating-case, in a stove temperature, where they will root in the course of a week or ten days. They should then be placed in a more airy situation, and will not require to be potted off, but may be allowed to remain in the pots, in which they were inserted as cuttings, until the time arrives when they may be planted in the beds.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Plant Stove and Greenhouse.

Stove and greenhouse plants of all kinds should now be re-potted, not necessarily into larger pots, unless these be required; but the soil, &c., in which such plants are growing, should be carefully examined at least once every season; and this is a suitable time for such operations. See, therefore, that the drainage is in all cases efficient, as, without this necessary condition, no plant in a pot or tub can long remain in health. Of all winter-flowering plants, the various varieties of the *Camellia* are, perhaps, the most appreciated. The flowers, however, which they may produce after this time, are of less value than those which expand during mid-winter; and, in order to induce, as far as possible, an early habit of blooming, the plants, or, at least a portion of them, should now be re-potted or surface-dressed, as may be found necessary, and any blooms or unexpanded bloom-buds remaining upon them should be rubbed off. The plants should then be placed in a moist and tolerably high temperature, such as that of an early Vinery, where they should be freely syringed once or even twice each day, in accordance with the state of the weather; and, as the drainage will have been set right, they should also be freely watered at the roots when they require it, as drought is extremely injurious to them. The partial shade of Vines during the time when *Camellias* are making their fresh growth will be found to be beneficial to them rather than otherwise. These plants are frequently grown in a mixture of

peat and loam. Possibly, however, good fibry peat alone, in a somewhat rough condition, is the best material in which to grow them; while the broken up roots of the common Ling, or Heather, is an excellent material to place in the bottom of the pots, to act as drainage. In the propagating-house or pit, bedding plants of all kinds should be increased by means of cuttings or otherwise, as rapidly as possible, until the requisite quantity of each sort is secured. Bedding Pelargoniums, in small pots, should now be shifted into pots of larger size, and rooted cuttings of the same in store pots should be potted off singly. Such kinds as Blue Lobelia and the Golden Feather Pyrethrum, sown early in February, will now require to be pricked out into seed-pans or boxes, where they may remain until they are required for planting in the flower-beds. Various kinds of tender and hardy annuals may now be sown in a gentle warmth in pots or pans, to be afterwards pricked into boxes, &c., and the hardy species should be finally planted out where they are to flower early in May, and tender kinds, such as the Celosias, &c., should be shifted into their flowering pots.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Bouquet Flowers.

Amongst other blooms at present obtainable for bouquet making may be enumerated the following, viz., Azaleas, Bouvardias, Camellias, Carnations, Cinerarias, Cyclamens, Deutzias, Ericas, Encharis, Euphorbias, Fuchsias, Gardenias, Heliotrope, Hyacinths, Heaths, Lily of the Valley, Mignonette, Narcissus, Pelargoniums, Primulas, Roses, Snowdrops, Spiræas, Stephanotis, Violets, and white Lilac. Button-hole bouquets consist generally of a Rose-bud, a half-blown Camellia or Gardenia, and some other smaller flowers. A pretty flower for these miniature bouquets is the blue Forget-me-not, obtained by lifting a few clumps of it from the open ground, potting them, and placing them in a warm house, where they speedily open their blooms and afford a stock to cut from. If placed with a Gardenia, the blue Forget-me-not forms an effective contrast; but, with such a selection as I have enumerated above, both hand and button-hole bouquets may be made to suit all tastes.—A. HASSARD, *Upper Norwood.*

Indoor Fruit Department.

Vines.—It sometimes happens that a few bright hot days about this time cause the buds in late Vineries to burst into leaf without the assistance of fire-heat. When such is the case, and low temperatures occur afterwards, the young shoots are sure to receive a check, unless strict attention is paid to giving a little fire-heat to prevent the temperature from falling at anytime below 55°. All shoots tied after this time should be laid in as equally as possible, so as to shade and keep the interior of the house cool throughout the summer. Quick-growing leading shoots should not be allowed to inter-twine amongst the wires, as they are generally inclined to do; but should be kept constantly tied into proper position. It is a good plan to take the points out of the leading shoots when the young growth is about 4 feet long; this strengthens the part which has to be retained, instead of the extreme point which will ultimately be cut off. The shoot should not be kept continually pinched at this part, but should be allowed to proceed to the top when the new growth appears willing to go that length. Until growing Vines are finally pinched, they must be gone over at least once a week. No shoot must be permitted to grow unmolested to 3 or 4 feet, and then have the half of that length pinched or cut away. Vines in the earliest houses should be well syringed every day, so as to prevent red spider from lurking about, ready to break out whenever this operation is discontinued. Syringe the small rods of newly-planted Vines every morning and evening. Those planted outside should have their roots protected with boards, or some other covering, if excessive wet prevails.

Pines.—All Queens should be started into fruit by this time; therefore, see that the bottom-heat does not decrease or vary in any way. It is sometimes suitable to turn the bottom-heat on one night and off another. A long thermometer for indicating bottom-heat should be in every bed, as no accurate account of it can be kept by means of sticks. Plants of all sizes, potted a week or two ago, will soon require to be watered at the root. Nothing less than what will moisten the entire ball will be sufficient; and, where the soil is dry, it takes the water a considerable time to work its way into it. Lately-potted suckers must not be watered until it is ascertained if the fresh roots have reached the sides of the pot; and, unless this is the case, it is best to delay watering until they are to be found there.—J. MUIR.

Kitchen Garden.

Sea Kale.—The thongs or pieces of roots that were trimmed off the large roots of Sea Kale, when they were taken up for forcing, and that have since been covered somewhere with soil to keep them fresh, may now be cut into pieces from 4 to 6 inches long, and planted in well prepared ground, in rows, from 15 to 18 inches apart, and from

6 to 9 inches asunder in the rows, keeping, of course, the thick ends uppermost, and just covering them with soil. Another way of treating them is to lay them in thickly in light rich soil, in a sheltered place, until signs of growth appear, when they should be taken up, all weak growths rubbed off, or, at least, thinned, and planted in rows, as has just been recommended. In wet, heavy soils this is the best plan to adopt, as the plants get a better start, and become fuller and earlier developed. In deep sandy loams, or, in fact, on any soil in good condition, fine strong Sea Kale, suitable for forcing, may be raised in one year, from seed sown now in well-prepared land, in drills, 15 inches apart, and 2 inches deep. As soon as the plants appear dust them freely and frequently with soot or lime, and thin them out finally to 6 or 9 inches apart. A dressing of salt about June will have a stimulating effect upon their growth, and all the further care required will be to keep the surface of the ground loose with the hoe. I know that an idea prevails that when seedling roots are forced they are more liable to run to flower than plants raised from root cuttings; this does not, however, accord with my experience. Where Sea Kale is forced in the open ground, without removal, under pots and manure, if new beds are required, they may be planted or sown any time between this and the first week in April. The beds may be made 4 feet wide, with 18-inch alleys between them, and the plants may be planted in groups of three in a patch, and the groups should be 2 feet apart each way; thus, a 4-foot bed will carry two rows of pots when forcing begins. If the soil is at all heavy, everything available in the shape of burnt earth, sand, road-scrapings, &c., should be forked in to lighten it. If seeds are used to form the plantation, they should also be sown in patches 2 feet apart, and thinned out finally to three plants in a patch—of course leaving them close enough together, so that they will be easily covered by the pots used for forcing. If a frame that has been used for early Potatoes, or any other early crop, that has been removed, can be spared, plant it now with French Beans, in rows 18 inches apart, setting the Beans 4 inches asunder in the rows; one of the small dwarf-growing kinds is best for this purpose. If there is not a frame vacant now, but will be shortly, the Beans may be sown in a box, and transplanted afterwards. French Beans, in forcing-houses, will now require a good deal of care to keep them free from red spider; the moment it makes its appearance the plants should be discarded, as the produce after that will not pay for the risk incurred. This is a good time to plant a good breadth of Green Windsor Beans, as the later crops, although useful, are usually not so prolific, and are more liable to the attacks of insects. Early Potatoes on warm borders, now coming through, will require unremitting attention in taking off the covers every fine day, and covering again at night. The nights, for the next two months, will be uncertain as to their temperature. A mild day may be succeeded by a frosty night; therefore, it is best to cover up, even on mild evenings. Late Turnips that are now showing signs of growth should be taken up, have their tops cut off, and the roots placed in a cool dry cellar or north shed; in such a position they will keep good for some time. If not already done, all Parsnips left in the ground should be taken up, and the ground manured and trenched for the next crop.—E. HOBDAV, *Ramsey Abbey.*

THE FUTURE OF THE ROYAL HORTICULTURAL SOCIETY.

ONE word in answer to "A. B." (see p. 231). My first letter in THE GARDEN, dated 21st October, 1873, says:—"Consider what a vast number of well-to-do people, fond of their gardens, there are now in the country. Very many of them would now be willing to help horticulture, if it did not cost them much money or trouble. I would make the annual subscription a guinea." As I wrote then I think now. So much for trusting to the guineas from gardeners; though I hope we shall have the best of their class as Fellows. I well know of the excellent Horticultural Society in Manchester, but the central society does work which no district society can do; so our claims do not in any way clash. The main grounds on which we can claim general support are that fruits, flowers, and vegetables, come from all parts of the country to Chiswick and South Kensington, are judged, and the verdicts circulated all over the country the same week, excellently reported by the horticultural press; and thus are the property of town and country alike. Having long served on the council of the Society of Arts, where the importance of friendly relations with societies having kindred objects, all over the country, was fully understood and carried out, I look forward to the time when the same may be said of the Royal Horticultural Society. I thought Manchester was a good place to seek guinea Fellows, because there clear heads and ample means are to be found. We have some excellent names of would-be guinea Fellows from the Manchester district, and expect more. I have no right to object to the expression

"pet crotchet," because every strong belief becomes more or less a crotchet; but if eight years on the council, and service in so many offices in the Society, do not give means of forming a correct judgment, nothing will.

GEORGE F. WILSON.

Heatherbank, Weybridge Heath.

SUNKEN BOILERS.

In reply to Mr. Dunbar (see p. 232), I wish to state that our raised boiler is now working a range of lean-to houses, 270 feet long, divided into seven compartments. There are pits supplied with bottom-heat in two of the compartments, and there is also a flow and return pipe through a Mushroom-house at the back. Although there is not much variation in the level of the houses (about a foot) there is a considerable deviation in the level of the pipes, including many sudden dips under doorways, &c., and in one case, to reach a house at the end of the range, the flow descends and passes outside in a brick drain under the north wall for 40 feet, before it reaches and ascends into the house. Of course, I do not say a stoke-hole cannot be made watertight with cement; under certain conditions I am aware that it can, but those conditions cannot always be secured. In our case, after incurring a very large expense, it ended in failure; in fact, the year before the boiler was raised, from December to March, there was more than a foot of water in the stoke-hole constantly, and when pumped out it rose again to the same level in less than an hour. Only those who have experienced it can form an idea of what an intolerable nuisance it is to be swamped in this way. Now, if it can be proved, which I believe it ultimately will be, that deep stokeholes are not a necessity, and that there is no advantage gained by placing the bottom of the boiler much lower than the lowest pipe, a considerable expense will be saved. As regards consumption of fuel, my estimate was based on the boiler's average consumption for a series of years; and I am convinced the case is not overstated. One of the places I had in my mind, when I wrote the paragraph at p. 188, and the nearest to London, was the Huntingdon Nurseries of Messrs Wood and Ingram. Their largest boiler was raised, about two years ago, so that the top of the boiler (a large tubular one) is 6 feet above the flow-pipes; and it is now heating, in a most efficient and economical manner, a considerable number of houses in several blocks or ranges. In a letter from that firm that I now have before me, they state that they never had such heating power before. These are facts that cannot be contraverted. I may say, however, that the apparatuses, both here and at the Huntingdon Nurseries, were supplied by, and the alteration carried out under the superintendence of, one of the oldest firms of hot-water engineers in the country. E. HOBDAV.

Ramsey Abbey.

The Hydra Registering Thermometer.—Under the title of "The Hydra," Messrs. Smith and Beck, of Cornhill, have produced an exceedingly good thermometer for registering the highest and lowest temperatures occurring between the hours of observation. It is a considerable improvement on the old form, inasmuch as the bulb, being divided into three heads (hence the name), has a much greater surface exposed to the air, and the instrument is more rapidly affected by changes of temperature—the fault of the old form being its sluggishness. The Hydra is manufactured with the greatest accuracy, the indications of the two columns being identical at all temperatures at which we have tested it. It is hardly requisite to say that a registering thermometer should be hung out of the direct rays of the sun, and that the registers should be set at the same hour each day, when the highest and lowest temperatures of the previous twenty-four hours may be noted. As a good working instrument at a moderate price, we can strongly recommend the Hydra.

OBITUARY.

MR. HENRY HIND.

This gent man who was devoted to horticulture, was recently murdered at Naples. The details of his death are given in the daily papers, and need not be reported here. I was introduced to him last spring at Naples, by Mr. Leigh, of Barham Court, as one conversant with the gardens at Naples, and spent some time in them with him. One more inoffensive, by nature or by his avocation, never met death at the hands of an assassin. There is reason to believe that Mr. Hind was murdered by order of the Secret Society of Market Gardeners in Naples. His skill in the cultivation of flowers had enabled him to undersell other florists, and a deputation from that society had, shortly before his death, waited upon him and demanded that he should raise his prices, which he had refused to do. Unfortunately, the fact that Mr. Hind's accession to fortune would remove him out of their way was unknown to the conspirators. W. R.

NOTES AND QUESTIONS—VARIOUS.

Cupressus Leeana.—A fine pyramidal plant of this Cypress, growing in the Feltham Nursery, is producing cones for the first time. This variety was raised many years ago, by Messrs. Lee, at the Hammersmith Nursery; and has always been, until now, considered to be a male Cypress.—A. D.

Lime Poison to Rhododendrons.—As a lover of Rhododendrons I beg to say one word in their behalf. Professor Owen in his article on "Lilium giganteum," tells us that when making a bed for Rhododendrons he put some lime with the bog-earth and loam used for that purpose. Surely he must have known that lime is most injurious to these plants, in fact, poison to them.—T. B.

Conifers at Keir, near the Bridge of Allan.—I observed in Sir William Stirling Maxwell's pleasure grounds, the other day, some very fine Conifers, and amongst them a female *Araucaria imbricata*, quite 45 feet in height, branched from one foot above the ground, at regular intervals apart to the top. When seen from a distance this tree has the appearance of a gigantic cone.—WILLIAM LAURIE, *Lynnwood, Alva, Stirlingshire.*

Laurus latifolia.—Why is this fine Laurel not more abundantly grown? It is quite as hardy as the common kind, quite as robust and free, and its noble leaves—almost as large and glossy as those of a *Magnolia*—render it much more ornamental. Large masses of this fine Laurel, growing as the common Laurel is now seen, would be extremely ornamental. It is certainly a shrub to which the attention of planters should be directed.—D.

Geraniums for Forcing.—To all who have great demands made upon them for cut flowers at all times of the year, but particularly at this early season, I would like to say that three of Mr. Pearson's Geraniums are first-rate for forcing purposes, viz., Mrs. Hetley, E. J. Lowe, and Colonel Holden, the last being this year the best of the three. Usually, E. J. Lowe is the best, but this year even the Colonel beats that kind by a long way.—N. H. P.

Agrostis nebulosa and Briza maxima.—These Grasses, grown in pots, are valuable for intermixing with flowering plants in greenhouses and where stands of plants have to be kept in rooms; or where the decoration of fireplaces forms part of a gardener's duty they are of greater service still. Seeds of these should be sown now, at latest, in 48 or 32-sized pots, and grown in a cool structure. Other ornamental Grasses may also be sown, but these are superior for the purposes just named to any others.—R. P. B.

Oncidium Weltonii.—A specimen of this, with twenty flowers on a spike, is said (see p. 232) to be the finest yet produced. Allow me to state that I have had plants of this *Oncid.*, and have shown them at Manchester and elsewhere, with two spikes on one bulb—one with forty-six blooms on one spike and one with forty, eighty-six flowers in all—in perfect freshness and beauty. A plant, which I exhibited at Leeds last June, produced three spikes from one bulb, and had over seventy flowers expanded at one time.—E. MITCHELL, *Broughton, near Manchester.*

The Purple Fruited Guava (Psidium Cattleianum).—This is a most desirable addition to the dessert during the summer and autumn months, and this variety of Guava being very easily managed, should be more extensively cultivated than it is. Plants of it, when grown from seed, commence bearing at three or four years old, and they do well in Vineries or other houses, not started too early. A house, from which frost is excluded, is all that is required in winter, and under favourable conditions of growth, fruit is produced abundantly; it is extremely palatable for dessert, and makes a delicious preserve.—W. COX.

Planting Vines after Growth has Commenced.—I had five Vineries to plant last spring, and I had all the eyes on the rods "broken" on purpose about half-an-inch previous to planting. The roots were well shaken out of the soil in which they were growing, and planted carefully in the fresh soil. They were then watered with tepid water, and, singular to say, they received no check whatever, but, on the contrary, grew away strongly. I may add that they were pruned back early in winter to within 3 feet of the pot, an operation which caused them to plump up their buds without bleeding, previously to starting into growth, which they were allowed to do quietly, and they soon reached the top of the house, which they filled with dark leathery green leaves that have hitherto resisted red spider.—J. MILLER, *The Gardens, Clumber.*

Fruit for Table Decoration.—I notice (see p. 225) a useful article on this subject; but it relates wholly to flowers, while for the decoration of a breakfast table I know of nothing so good as a first-class pot of Strawberries covered with fresh Moss, and having the fruit skilfully tied out, inviting, as it were, the guests to help themselves; for it is a well known fact that a single fruit gathered by oneself is worth a whole handful gathered by others. I have also used for large dinner parties—say forty guests—pot Vines growing in 16-sized pots, each bearing half a dozen bunches of Grapes, as noticed in THE GARDEN some months back. By way of change, too, a black Jamaica Pine, shaken out when the fruit is ripe and re-potted in a small pot, placed in the centre of the table with pot Vines at each end has a fine appearance.—R. GILBERT, *The Gardens, Burghley.*

Growing American Cranberries.—In answer to your correspondent, E. W. Cook (p. 222), I may say that, so far as my experience goes, these do best on a level surface, where the beds can be occasionally flooded or irrigated, in the same manner as are water meadows. Still, I think he would be successful in their culture on the ground, and in the situation, he describes. I would, therefore, advise him to form beds 4 feet wide, and divert the overflow from the pools by a row of 2½-inch drain-pipes to each bed. They will only grow in peat or bog earth; and this should be of the poorest description. If it be what is considered "good" peat, add a large quantity of pure sand, which will cause the plants to be much more fruitful than if grown in peat only. There should be two rows of plants in each bed, and the plants should be 18 inches one from the other. In Sussex, there would not be any danger of injury from spring frosts when they are in flower.—W. WILDSMITH, *Heckfield.*

Watercresses without Water.—When last autumn I dressed a bed of soil in the greenhouse with some sifted dredgings from a ditch before planting out Pansies on it for the winter, I soon found, amongst other aquatic plants that sprang up, a small one of Watercress. This is now a good-sized plant, and would yield a capital picking of side-shoots. I simply kept it well watered, and it grew continuously, but, as the house was a cool one, I have concluded that the cress wanted a little heat. To reserve beds specially for Cresses would scarcely be necessary in any large place, where there is plenty of room at disposal in Vineries and other warm houses. What should be done is, to get a quantity of rooted shoots of the Cress pricked out into shallow boxes late in autumn, to keep them in a cold frame, and to bring them into heat as wanted. If kept freely watered, there can be no doubt that these cresses would grow rapidly, and many a nice gathering might be obtained from them during the winter months.—A. D.

"This is an art:

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

A GOOD AND DURABLE LABEL.

ANYONE who has a large collection of plants—be they Roses, Conifers, or herbaceous subjects—must be impressed with the necessity for a good system of labelling. Especially is a good system required for herbaceous plants and bulbs, which disappear annually altogether; and so run the same risk, if their place be not clearly and permanently ticketed "engaged," as first-class passengers in an excursion train—viz., of having third-class passengers thrust in on the top of them. Three things are necessary in a thoroughly good label—durability, legibility, and unobtrusiveness; and to these most people will be inclined to add a fourth—cheapness. They must be durable in the sense not only of lasting long, but of keeping the inscription long; they must be legible, not, as in some public parks and botanic gardens, in the sense of an

Fig. 1.

Fig. 1.

advertisement, but legible as a reference when information is really wanted; nobody, at least in a private garden, wants the names of plants "shouted" at him by labels of the type in figs. 1; and they must, as I have said, be unobtrusive, for nothing looks more pedantic or unsightly than quantities of white labels all over a bed. I have been fortunate enough to hit upon what I believe to be the one of all the many kinds of labels which are offered to the public that best combines all these qualities; and it may also be used with equal advantage for Roses, Conifers, fruit trees, in short, for anything which requires a label. It is the ordinary trefoil-shaped zinc label attached to a piece of galvanised iron wire as thick as a goose-

Fig. 2. (Two-thirds natural size.)

quill. The mode of attachment is shown in fig. 2. The end of the wire is bent to an acute angle, and is then hammered over the hole in the label. The wire should not be too thin, as it is then apt to bend over in the ground; nor too thick, as it is then difficult to beat it over the label. With the thickness named, the process is easy and rapid, after the wire has been cut into lengths of 1 foot or 14 inches with a cold chisel; the face of the label is then cleaned with sand-paper, and the name of the plant written with the usual zinc-label ink. The cold grey colour of the zinc is very unobtrusive in a border, and the presence of several dozen of these labels is no eyesore, as they may be thrust in to within 2 or 3 inches of the ground. They remain perfectly legible for years. Some here, put out in 1867 (eight years ago), are nearly as legible

now as then. The same label may, if necessary, be used over and over again, for if the old inscription be rubbed off with sand-paper, a fresh surface is presented. Another advantage of this kind of label is, that it may be used on rock-work without any damaging effect. The wire may be thrust between the stones till the label rests close to the ground, and it is legible without being pulled out. Many a plant is lost for the want of durable labels put in at the time of planting, and these appear to answer every purpose. SALMONICERS.

CULTURE OF BOUVARDIAS.

BOUVARDIAS have been long known in this country; but, until recently, they have not met with that attention which their merits demand. Of late years, a system of cultivation more in accordance with their natural requirements, and the introduction of varieties greatly in advance of older sorts, have done much to place them in the foremost rank amongst winter-flowering plants. From this, it must not, however, be inferred that they are exclusively winter and spring flowers; for, if the plants are well managed, and grown in sufficient quantities to furnish a succession, they may be had in bloom continuously. Few plants, indeed, have so many desirable properties as Bouvardias; and their comparatively small size—from 1 foot to 18 inches through—renders them suitable for even the smallest collection. Not only are they strikingly beautiful subjects for the warm conservatory when in flower during winter, but their blossoms are well adapted for cutting—colour, form, and their delicious fragrance, combining to make them especially suited for bouquets and coat flowers, as well as for intermixing with other blooms for decorative purposes in the many ways in which flowers are now used. The continuous habit of flowering possessed by Bouvardias is another point in their favour. When well grown, and in a genial atmosphere, the same plants will keep on blooming for three or four months at a time—a consideration of importance, as where such is the case fewer plants are required to be grown. As regards cultivation, young plants are much to be preferred to old ones for several reasons; they flower and make growth more freely; they are less straggling in habit, and the blossoms are larger than those on old plants. It is, therefore, better to strike fresh plants every season, and to discard such as have bloomed. Cuttings from them should be struck in spring in a brisk heat, and, when well rooted, they should be grown on freely, either in pots or planted out, and in September are transferred to the pots in which they are intended to flower; but, in whichever way they are grown, they require very rich soil, consisting of two parts of well decomposed rotten dung and leaf mould, and three parts of good loam, with a little sand. After being struck they should be planted out in a good light pit in a genial growing temperature through the summer, and sufficient water should be given at the roots, and in syringing overhead, to supply their requirements in that way, and to keep them clean and healthy; they must also have air in sufficient quantity to induce sturdy growth. Plants that are turned out into pits will, as in the case of almost anything else that will succeed under such treatment, be found to make stronger growth than such as are confined in pots. Planting out is also a great saving in the matter of labour in watering, where they are grown in large quantities; but, when transferred to pots, that operation must be conducted with care, taking them up with their roots as perfect as possible, and potting them in soil similar to that just described. They must afterwards be kept in a close warm moist atmosphere, until they get fairly established, and are in an active growing state. It must then be determined what portion of the stock is to be brought on for early winter flowering, and what is to be kept for later use and for spring. The latter will require to be kept in an intermediate temperature, and just moving a little through the early part of the winter. Bouvardias do not succeed well in the temperature of an ordinary greenhouse at this season. Such as are required for flowering in December, and in the beginning of the year, must be kept in a brisk heat night and day all through November, and onwards, and they should be raised near the glass; 70° at night is a good temperature. So treated, they will

keep on flowering for months, and every bit of growth which they make will throw up bloom. Bouvardias strike readily from root-cuttings an inch long, put in pots of sand in a brisk bottom-heat; and, when they have pushed shoots an inch or two in length, they should be potted off singly, and kept on growing. *B. Humboldtii corymbiflora* is one of the best varieties in cultivation. The tubes of its flowers measure 3 inches in length, and the lobes of the limb $1\frac{1}{2}$ inches across; these are pure white, produced in bunches of a dozen each, and are highly perfumed. Another white and very beautiful dwarf kind is *B. jasminoides*, a free-growing sort, and a profuse flowerer. *B. Vreelandii* is another dwarf, and extremely free-flowering kind, which is continually in bloom—a beautiful white flower, with a faint blush tinge on the outside. Another variety, called Maiden Blush, has bright blush-pink blossoms, and is a very distinct and desirable variety. *B. Hogarthii* is scarlet; it has a good habit of growth, and produces fine trusses of flowers. *B. elegans* is said to be a sport from *Hogarthii*; its flowers are of a scarlet-tinged carmine, and very beautiful. These are all kinds that may be relied upon; they are, indeed, the best in cultivation, and, whether one or all of them be grown they will give equal satisfaction. At the same time, it may be as well to say that, for general usefulness, the white varieties are the best.

T. B.

DISROOTING CAMELLIAS.

I CAN understand Mr. Gadd's experimenting in disrooting his Camellias; but I cannot understand his advising such a proceeding in ordinary practice. Their succeeding, after such treatment, is simply one more proof of the tenacity of plant life, and its recuperative powers after vigorous root-pruning. If "N. H. P." followed this advice in planting his Camellias out, I fear he will have but little trouble in gathering the flowers which they may produce for some time to come. In planting out Camellias at this season, just before they commence growth, and when all their feeding roots are growing, not a fibre should be disturbed on the outside of the ball, where the principal active roots are. I would not even disturb the crocks, but would make the holes 18 inches wider than the ball of each plant, and 3 or 4 inches deeper; then place each plant in its proper position, and, with a stout rammer, make the soil surrounding, for 9 inches, as solid as the ball itself, leaving the new soil a little higher all round than the ball, and keeping it so until the plants have got fairly established; this is to prevent the water passing down the new soil, and leaving the roots dry. To still further assist the percolation of the water through the old ball, a good plan is to take a stout round iron skewer, and pierce it downwards right to the bottom, in a score of places; plants so treated, if the border in which they are planted has been well made, and they are properly attended to in other respects, will grow very rapidly. When planting out is done in the autumn, when the roots are quite at rest, a portion of the old soil may be taken away, and the roots a little opened out; but any interference with them at this season will stop the coming summer's growth more or less.

T. BAINES.

Spiræa palmata not a New Plant.—I have recently had a discussion with a mutual friend of yours and mine, who insists that this so-called new plant, sent out by some of your nurserymen three or four years ago, must have been then new, or it would never have been endorsed by so many respectable firms, editors of horticultural journals, and professional botanists of repute. But now for a few facts: Thirty years ago I was an apprentice at Melville Castle, where one of the largest private collections of herbaceous plants in Scotland was grown at that time. I was then fairly well up in nomenclature, and well remember that we grew in abundance plants known as *Spiræa palmata*, besides a full collection of other species of that genus. When the "new" *Spiræa palmata* was offered at half-a-guinea a plant, I became a doubting purchaser, and doubted still more as I became impressed with the idea that the appearance of the plant was familiar to me as an old acquaintance of thirty years ago; when it flowered the identification became complete, for the *Spiræa palmata* of the Melville collection of 1840 was the same as my imported London "novelty" of 1870. To make assurance certain, a friend, also a graduate of Melville, sent me last summer a plant of *Spiræa palmata* that had originally come from the Melville district, but which he had grown for over a dozen years in America, which proved to be identical in every respect with my "new" *Spiræa palmata*.—PETER HENDERSON, 35, Cortland Street, New York.

NOTES OF THE WEEK.

— AT this season, when good dessert Apples are scarce, it may be well to note that the best-flavoured and most juicy Apple now in Covent Garden is the Old Nonpareil.

— AMONGST hardy herbaceous plants suitable for forcing, few are more effective than the *Spiræa Aruncus*. The elegant feather-like plumes of this Meadow-sweet have been brought into Covent Garden Market during the past week.

— SIR ARTHUR GORDON, the new Governor of Fiji, has, in reply to a requisition signed by the Horticultural Society, promised to assist the Society in regard to the importation of plants which are indigenous to the islands just acquired by Great Britain.

— THE eighth edition of Mr. William Thomson's "Book on the Vine" is, we understand, in the press, and will shortly be published in an enlarged and revised form.

— THE case of "The King of Portugal v. Carruthers and others," relating to the possession of the Welwitsch Herbarium, which was partly heard last Monday, has been postponed till next term, on the suggestion of the Vice-Chancellor, that the matter might be settled out of court.

— MR. MEREDITH'S Vineyard at Garston has been purchased by the Cowan Lime Heating Company, who have determined, not only to make use of it as an exhibition ground for their patent heating apparatus, but also as an establishment in which Grapes will be grown as well, if possible, as they were by Mr. Meredith.

— WE are requested to announce that the Committee of the new Horticultural Club have nearly concluded an arrangement by which they will obtain the accommodation of a club-house, within three minutes' walk of Charing Cross, and overlooking the Thames Embankment. There will be a reading room, dining, drawing, billiard, and smoking rooms, and all the adjuncts of a West End club; while for country members bedrooms will be provided.

— A PLANT of the Scarlet Tree Rhododendron (*R. arboreum*) is now blooming freely in one of the villa gardens facing the Richmond Road at Kew. In warm situations in the southern counties, this Rhododendron might be tried out of doors, and in Devon and Cornwall it would certainly succeed; but, in most parts of England, its proper place is under glass—a position which it well deserves. It flowers early; and, when out of doors, the blossoms are injured by frost.

— REFERRING to what was stated (see p. 245) respecting the Seville Long-pod Bean, allow me to say that in Spain and the South of France it commonly grows 3 feet in height, even more, but in the open ground in England its average growth will probably seldom be over 2 feet. The leaves are often gnawed by insects infesting their undersides. The seed is paler and brighter than that of the common Long-pod Bean, and is not of a handsome yellow colour.—D. GUILLENEUF.

— MONSIEUR A. TRUFFAUT, of Versailles, contributes a paper this week (see p. 257) on a remarkably successful mode of striking cuttings, in use in his own garden at Versailles. By this method we have seen strong plants of *Dracænas*, &c., established in four weeks from the time when the cuttings were taken off; and to see the quantity of cuttings of tropical plants that are struck by simply placing them, according to his plan, on the saw-dust, is most interesting.

— MR. ELLACOMBE, of Clyst St. George Rectory, Topsham, Devon, father of Mr. Ellacombe, of Bitton, and one of the oldest and most extensive cultivators of hardy flowers and herbaceous plants in this country, has sent us specimens of the brilliant *Anemone fulgens*, together with various other South European kinds. Mr. Ellacombe states that these *Anemones* and the blue *A. apennina* succeed well with him at Topsham, but that there the common Red *Hepatica* entirely fails.

— ONE of the chief products of Auckland, New Zealand, is Kauri gum, the semi-fossil resin of *Dammara australis*. This resin is found at a depth of from 2 to 3 feet from the surface over a large area of land once covered by Kauri forests, but now barren and almost unfit for cultivation. In these waste lands there is no restriction enforced by Government as to the right of digging for the resin, and it is calculated that in various parts of Auckland as many as 2,000 men have found employment at one time digging up the Kauri resin. This number, however, is now considerably reduced, owing to the demand for labour in other directions; nevertheless, large quantities of the resin are required by varnish-makers in this country, and consequently many persons still find employment in digging it. The Maoris bring a considerable quantity to market. The best quality fetches in the market at Auckland from £30 to £33 per ton. At this price the gum-diggers are able to earn from £1 10s. to £4 per week; the average earnings, however, are about £2 per week. In the three years from 1870 to 1872, there were exported from Auckland 14,276 tons of Kauri resin, valued at £497,199.

THE FLOWER GARDEN.

SWEET PEAS.

I HAVE often observed, when these were grown for several seasons in succession on the same piece of ground, that they gradually dwindled and became weaker in growth. Change and rotation are, therefore, beneficial to them; and, in most places, this can easily be given them. One of the most common varieties is the scarlet Invincible, the blooms of which are all of one colour, and extremely showy; this kind is often grown by itself, but I prefer to see varieties possessing other colours mingled with it, such as sorts that produce white, purple, lilac, bluish, and black blossoms, and when all are equally mixed in a single row they look exceedingly well. Where the borders along the edges of the walks in the kitchen garden are planted with flowers in summer, it is always desirable that some kind of floral screen should divide the flower from the vegetable quarters, and for this purpose Sweet Peas are very valuable. In moderately rich soil they grow 6 feet high, and flower from the ground to the extreme points. In many instances they bloom so profusely that nothing but blossom is visible, and their long stems and exquisite odour render them great favourites for bouquet making, a purpose for which a very short row will supply a profusion of flowers from July until the end of September. I have seen the seed sown in pots and brought on under the protection of a frame from about the beginning of April until the middle of May, when the young plants were planted out in rows early in the season, like ordinary Peas. This plan has the effect of bringing them into bloom a few weeks sooner than those sown in the open ground at the same time, but I do not think that those started in pots remain so long in bloom as those sown in the position which they are intended permanently to occupy; I prefer, therefore, the latter treatment. The seed should be sown in 3-inch deep drills, not later than the beginning of April. The ground should previously be well manured with rotten dung, and, as I before stated, a change—although it should only be a foot from where they grew last year—is very advantageous to them. When the weather is backward about the time they appear above ground, the rods should be put in, and thus ward off cutting winds. I always like to see Sweet Peas staked with clean Beech rods, and not with rough-looking Spruce or Larch branches, which are not in keeping with the flowers during the summer. When the weather is exceedingly dry, liberal waterings of liquid manure helps greatly to sustain their vigour. Every one may save his own seed by allowing a few of the first opened flowers to form pods, but the last blooms must not be depended on, as the frost generally nips the capsules before the seed is matured. After the seed has lain for a week or two, as it

was gathered to dry, it may be cleaned and stored in a paper bag in a dry room until it is wanted the following season. It is singular that Sweet Peas are not oftener cultivated in pots for greenhouse and conservatory decoration than we generally find them; they do as well, and are quite as ornamental in pots as elsewhere, and for mixing with other greenhouse subjects have an effect that is entirely their own. When it is intended to grow them thus they should be sown in 3-inch pots like those for planting out, and when they are ready they should be shifted into 7 or 8-inch pots, with a good quantity of manure about their roots to give them support; a deep cool frame, with the sashes removed, is a suitable place in which to

grow them after they have been finally shifted. As soon as the growth becomes too long to support itself, or shortly before such a length is reached, five or six Birch twigs, from 3 to 4 feet long, should be put in as stakes to keep them up; no tying, or anything of the kind is needed, as they twine round and hold on by the twigs. All they require, from the time when the stakes are put in until they are ready to adorn the conservatory, is close attention in the way of giving water. All the perennial or Everlasting Peas, as they are often called, are well worth growing extensively in herbaceous borders. *Lathyrus latifolius albus* is the common white variety, and *L. latifolius roseus*, *L. grandiflorus splendens*, and *L. rotundifolius* are all showy kinds, which associate well with the annual sorts. Their blooms are larger than those I have previously described, not so sweetly scented, but equally suitable and useful for bouquet making. The whole may be raised from seed sown about this time, and a patch of them here and there amongst herbaceous plants has a fine appearance. They do not always bloom the first season after being sown, but strong roots are formed during that time, which ensure a profusion of flowers the following year. They require staking throughout the summer, and the straw should be cut away level with the ground when it decays in autumn.

J. MUIR.

Triteleia uniflora.

TRITELEIA
UNIFLORA.

CONCERNING this pretty spring-flowering bulbous plant, of which the accompanying is an illustration, we have little to add to what

has already been stated in our columns respecting it. Its flowers, which are white, delicately flushed with blue, and marked through the middle of the divisions outside with a violet streak, are, individually, extremely pretty, but to be thoroughly effective they must be seen in the form of good-sized clumps. Of *T. uniflora* at least two varieties are in cultivation, one of which (*T. u. conspicua*) has larger flowers than those of the species, and the other (*T. u. lilacina*) has flowers of a pretty lilac colour. These, as well as the species, make desirable plants for rock-work, or for other conspicuous positions in the flower garden. They will succeed in any kind of soil; but, being natives of the sandy plains of Mendoza, that of a light character

suits them best. In mild winters established clumps of these *Triteleias* will bloom more or less from November till June, and when grown in pots under glass their flowers have such a cheerful and pleasing appearance during the winter and spring months as to render them well worth attention for that purpose.

The Friar's Cowl (*Arum Arisarum*).—This curious little *Arum* was flowering in the utmost profusion, in the Riviera, during the month of January, and its distribution would seem to be general. I found it mostly growing on the stages under the Olive-trees. It is a conspicuous plant. The spathe, which is hooded (and hence its name Friar's Cowl) is of a dull purplish-white, with darker longitudinal stripes, the stem that supports it being spotted, as in the Dragon *Arum*. The spadix, which is very slender, is incurved, and it thus adapts itself to the hooded spathe. It has no cirriform glands. The leaves are sagittate, with the lobes obtuse at the base. It has something of the carrion smell of the *Dracunculus*. *Arum italicum*, with its fine leaves most frequently veined with yellow, that are conspicuous throughout the winter, was also very abundant; but, as it does not flower till April, I had not an opportunity of seeing it. It is described by Reichenbach as having the spathe externally of a reddish-green, and white internally. The spadix is yellow. These two species I noticed commonly in the Riviera.—PETER INCHBALD, *Hovingham Lodge, York*.

Crocus Imperati.—I am glad to see this beautiful early-flowering species brought into notice, as it is undoubtedly one of the most delicately beautiful of all spring flowers, and a fit associate for the earlier *Narcissi*, *Iris stylosa*, *Iris* (*Xiphion*) *Histrio*, the dusky *Iris longifolia*, and hardy *Cyclamens*. I first became acquainted with this species from seeing a figure of it in Sweet's "Flower Garden," Vol. I., table 98, but I never saw living plants of it until this year, when I met with it in Mr. Barr's grounds at Tooting, forming a bed 3 or 4 feet square, in full bloom, in January, where it withstood wind, frost, and rain with impunity, notwithstanding the delicate texture of its flowers. Mr. Parker also, about the same time, kindly sent me cut blooms of a variety of it, in which the petals were nearly purple, and the sepals very faint lilac. Sweet, in his description, says, "flower without scent," but all the blossoms of which I have seen have been delicately perfumed. I must say a word about Crocuses in the form of cut flowers, for which purpose they should be plucked as soon as the buds are fully formed and before they expand. A little tact is necessary in arranging them to advantage, and for this purpose nothing is better than a flat glass dish fitted with wet sand. Care must be taken to insert the buds far enough apart among the Ferns or other foliage with which they are associated, so as to give them plenty of room to open, which they soon do when removed into a gas-lighted or heated apartment, and it is difficult to imagine anything more bright and beautiful than these flowers are when seen under artificial light and intermixed with plenty of fresh foliage.—B.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

A good Tea Rose for Market Purposes.—I was told the other day that from one dark apricot-coloured Tea Rose *Madame Falcot*, worked on a standard Briar stock, out of doors, Roses had been cut every year, to the value of between 30s. or 40s. a year. It is evident, therefore, that this is a useful Rose for furnishing cut bloom for market.—F. S.

Primula cortusoides as an Edging Plant.—Have any of your readers tried the old *Primula cortusoides* (not *cortusoides amœna*) as an edging for spring borders? We have a bed of it raised from seed. The leaves are very beautiful, and the recent night-frosts have not affected them.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

Cineraria maritima compacta.—This is a beautiful form of *maritima* with very elegant silvery foliage. It is dwarf in habit, which renders it particularly useful for combining or contrasting with dark-leaved plants. Undoubtedly when this plant becomes better known it will be extensively used for purposes of decoration. It possesses a hardy constitution, and has a light and cheerful appearance.—G. WESTLAND, *Witley Court*.

Sowing Hollyhock Seed.—This may be sown in pans now, and placed in a frame with a gentle heat. When the seedlings appear remove them to a cold frame, keeping them near the glass and well aired. When the plants have two rough leaves they may be planted out in an open situation, in light sandy soil, and in lines 1 foot apart and 6 inches from plant to plant in the line. In October they may be taken up and potted if of a choice strain, and be wintered in a cold frame, planting them out at the end of March.—Q.

Fine Specimens of *Lilium giganteum*.—I read with much interest Professor Owen's letter in *THE GARDEN* for March 6th, but am surprised to find that he considers the growth of his *Lilium giganteum* satisfactory. We have grown this Lily at Thursley, in Surrey, for several years, in ordinary garden soil, keeping it in a cold pit from the frost during the severe winter months; and have considered those that did not exceed 6 or 7 feet in height as failures. Our finest, last year, measured 9 feet 8 inches, from the top of the pot, and bore fifteen blooms, all perfect. Our bulbs came originally from Dangstein, where, I believe, they grow some, most years, wholly in the open ground. The plant, I understand, is a native of Nepal.—E. R., *Kensington*.

THE INDOOR GARDEN.

CULTURE OF THE CINERARIA.

AMONG soft-wooded winter-flowering plants there is none more useful than the *Cineraria*; and, wherever there is a demand for showy plants for conservatory decoration and cut flowers, it is invariably grown in quantity. There are now very superior strains of this flower obtainable from seed, and these render it unnecessary to propagate by cuttings—at one time the only means of securing good varieties, which, when once obtained, may easily be propagated, by annually selecting a few plants with the best flowers, and setting them aside in a house by themselves for seed, while the less select varieties are used for cutting from and for decoration. Their diversity of habit, form, and colour, and the wonderful size of individual flowers, are not surpassed by any other decorative plant, furnishing, as they do, so many shades of blue, purple, red, and white. The *Cineraria* can be grown into large specimens for drawing-room vases, or flowered in small pots for edgings in the conservatory, and it may be had in bloom from November to May. The cool moist months of winter and spring are, however, the most favourable to its growth and continuous flowering; as the sun gains power with the approach of summer, its fine broad trusses of bloom become short-lived, even where enjoying a cool house with shade. A little seed may now, or soon, be sown for the very earliest plants to come in bloom in October; another sowing should be made in May for winter blooming, and the last at the end of June for the latest spring plants. Prepare a pan or box for receiving the seeds by putting in plenty of drainage in the usual way, then filling in the roughest part of the soil within an inch of the rim, and pressing it firm, adding $1\frac{1}{2}$ inch of finely-sifted soil, consisting chiefly of well-rotted leaf mould, and a fourth-part of loam and sand; press the surface quite level and smooth, and sow the seeds over the surface equally, and again press with a board, without covering the seeds at all; place the pans in a moist close pit, where there is a little bottom-heat but no fire-heat, or in a shady part of a greenhouse; or, what is better still for these seeds and many others, in a warm north house; place a sheet of glass over the mouth of the pan until the seed germinates, when it must be removed, to prevent the seedlings drawing, and the pan replaced close to the light, in whatever house it may be. When the seedlings have developed two rough leaves, and can be easily handled, they should be transplanted into boxes, giving them 2 inches of space every way; place the boxes in a cold pit, and shade them from bright sunshine, taking care to keep the soil and atmosphere constantly moist; allow abundant ventilation, but no draft. When the plants begin to be overcrowded in the boxes they should be potted into 4-inch pots, and as the heat of summer increases, they should, at the end of May, be moved into frames, facing north; and, as the plants increase in size, and it is found necessary to pot them on, some into 6-inch and some into 8-inch pots, the frames will require raising on bricks, to ensure plenty of ventilation. Shelter and moisture, however, about the soft foliage, must be still maintained, for if the *Cineraria* be once allowed to become stunted and wiry in its growth, from neglect of water, or any other cause, the prospect of good plants is quite hopeless. Weak manure-water should be given them every time they are watered, after they have filled their pots with roots. The *Cineraria* is not particular as to soil. It will grow well in a fresh sandy loam, with a third part of well-rotted horse manure, or leaf mould, to which should be added a little coarse river sand. In the northern counties, the *Cineraria* may, in summer, be grown in the open air, provided the position be sheltered from drafts, and shaded by a wall or thick hedge. The position having been made moist by copious watering, the whole must be removed, about the end of September, under glass, and kept cool. In the dry, hot southern counties, a frame is, except in very favourable positions, necessary, to protect the plants from the hot winds. The north side of a high wall will, without the shelter of a frame, sometimes be found too dry for them to retain the necessary moisture. The latest sown batch of plants will be found the most easy to manage, and will turn out the best specimens, having the cool and moist dewy nights of autumn in

their favour. The *Cineraria* is particularly subject to the attacks of green-fly, especially in summer, but these vermin are easily destroyed by tobacco smoke. Fly will sometimes attack the roots, without any signs of it on the leaves, in which case the plants should be turned out of their pots, which should be inverted, the plants placed on them, and in this position should be fumigated, and then returned to the pots. Large specimen plants of the *Cineraria* may be grown by shifting the plants on into 10-inch pots, using some rough bones in the soil, but care must be taken that the plants never become in the least pot-bound before they are shifted into the flowering-pots; in other words, they must be kept steadily growing, without check, and when the heads of bloom are well up they may be opened out, and tied into shape by thin ties of bast to the rim of the pots, for which purpose perforated-rimmed pots should be used, as they are much better adapted to this work than the common pot, which necessitates the use of sticks. These specimen plants must be grown close to the glass, in a moist house, from which frost is excluded; weak liquid manure must be given regularly, and plenty of room allowed between the plants for the free circulation of air.

W. D. C.

NEW MODE OF STRIKING CUTTINGS.

THE number of foliage plants annually required in Paris for indoor decoration led us to discover some quick and economical method of propagation, by which we might be enabled to produce, at a small cost, large quantities of plants, principally *Dracænas*, *Ficus*, *Crotons*, *Aralias*, &c. For two years we

Section of M. Truffaut's Propagating-house, Versailles.

have, with the most satisfactory result, adopted the following method, which I believe is little, if at all, known in England. Experience has shown us that in a plant-house, without the aid of either bell-glasses or frames, cuttings will take root well and rapidly when inserted in saw-dust, if they are supplied with a sufficient amount of heat and damp at their base and in the atmosphere. We have, therefore, made, expressly for the purpose, a house, the construction of which will be more readily understood after a glance at the accompanying illustration. It is an iron house, about 30 feet long, and 6 feet 6 inches in height, above the footway. The house is double glazed, in order that the exterior air, which would cool the atmosphere and injure the cuttings, may be excluded. The walls are of brick, and the house is built as deeply as possible in the ground. A foot-path, about 2 feet 6 inches wide, runs down the centre of the house, and on either side of this path two small walls (AA) enclose the soil, and support a table BB, formed of T irons, upon which rest tiles, placed with a small space between them, in order that the water accumulating after watering the slips may be carried off. At intervals in the wall (at D) openings of about 7 inches in length, and about 5 or 6 inches in height are made, which may be closed or opened at will, by means of cast-iron sliding panels, which enables us either to retain or get rid of the hot damp air escaping from the piping which, as will be seen from the sketch (CC), runs through the length of the house, and are enclosed in a reservoir, built of bricks and cement, and filled with water. Upon the top of the table, formed, as we have said, of tiles, is spread a layer of

deal saw-dust, about 6 inches in depth. This kind, and that of Poplar, are the best; but the saw-dust of Oak must never be used, as it is very injurious to the cuttings. Such is the house when, in the middle of December, we commence the propagation of the plants. The house is heated for two or three days, so as to raise the temperature of the saw-dust to about 70°, and the cuttings are then made in the usual way, and inserted side by side to a depth of about an inch or an inch-and-a-quarter. In the case of *Dracænas*, we have no leaves attached, and this is the best way of avoiding rot. The leaves of *Ficus*, *Aralia*, &c., are left on on account of their size. The temperature of the air in the house should always be about 77° Fahrenheit, and that of the layer of sawdust from 87° to 90°. One of the indispensable conditions of success is the constant humidity of the air in the house. We obtain this result in some measure by the evaporation of the water contained in the tank through which the pipes pass, and by saturating with water the path, the walls, and the cuttings, which we soak every day overhead by means of an ordinary garden watering-pot and rose. Under these conditions, the slips of *Dracænas* take from ten to fifteen days to take root; *Ficus*, from fifteen to twenty days; *Crotons*, about eight days. As soon as the roots have attained a length of from $\frac{1}{4}$ to $1\frac{1}{2}$ inches each cutting is potted separately in a pot proportionate to its size, and is then returned to its former position. Eight days afterwards the roots will have nearly filled the pots. The young cutting, which has by this time become solidified, is transferred to a hot frame or to another house where it acquires all the necessary hardiness. We have only spoken above of certain kinds, because it is upon these that we operate to the greatest extent; but the same process of propagation will succeed quite as well in other cases, and more especially with soft-wooded plants. It will easily be perceived that this system has very great advantages, which, so far as a large number of plants are concerned, do away with the necessity for cloches or frames hitherto used. Furthermore, the size for cutting the slips is no longer a matter for consideration. We made cuttings this year of *Dracæna Mooreana* of 3 feet in height; of *D. amabilis*, of 23 inches; of *Ficus*, of 20 inches; of *Aralia pulchra*, 2 feet in diameter. We have struck since the 15th December from six to seven thousand cuttings of *Dracæna terminalis*, *Cooperi*, *Braziliensis*, *rubra*, and of all the novelties; 4,000 cuttings of *Ficus*, half of them being at least a foot in height; and, besides these, a large number of *Crotons*, *Selaginellas*, &c. We advise horticulturists to try this method in a low moist house, and, in giving heat, moisture, and light in sufficient quantities to the cuttings, they may count with certainty upon the result.

Versailles.

A. TRUFFAUT.

RE-POTTING AND TOP-DRESSING HARD-WOODED PLANTS.

IN an article on "Surface Dressing," by Mr. Muir (p. 203), after treating of its application in the case of several subjects, he speaks of applying it to "large plants of *Camellias*, firmly rooted into pots or tubs, and whose lives would be endangered by a complete shift." Allow me to say that I do not think there ever yet was an instance of *Camellias* being so rooted as to have their lives endangered by complete removal. As to top-dressing *Camellias* there is a considerable difference of opinion. I am acquainted with some who grow these plants well, who every season apply top-dressings; of course removing some of the existing surface soil to make way for the new. Many others, who grow their plants equally well, never surface-dress at all, and would never on any account be induced to do so. Many years ago I selected a number of plants that had not been re-potted for a considerable time, and surface-dressed them each season, for some five or six years; an equal number in an exactly similar condition I left untouched during this time, and at its expiration there was little difference in the two lots of plants so treated; what little advantage there was rested with those that had not been surface-dressed—the unavoidable mutilation of the roots in removing the old soil, to make way for the new, evidently doing a greater amount of harm than the new soil did good. Mr. Muir then goes on to say that "*Azaleas* may be benefited in the same way." Here his advice is as mischievous as it well could be. There are no plants in existence, not even hard-wooded *Heaths*, that are more susceptible of injury from interference with the surface roots than

Azaleas. The roots of an Azalea in good condition, from the surface to two or three inches below it, lie crowded together in the soil almost as closely as the hairs on the back of an animal; and it is utterly impossible to remove any of the surface soil without destroying them. Azaleas, also, less than almost any other plants, can bear meddling with the collar, a very small amount of soil placed to which will induce them to go off at this point. The mutilation of the roots of plants, especially those of an evergreen nature, and that are grown in pots or similar appliances, is much too lightly thought of. I am acquainted with numbers of individuals who essay the growth of hard-wooded greenhouse plants—Azaleas included—yet who never bring them to perfection; one of the principal causes of this is the way in which the roots are mutilated at the periodical pottings they receive. How is this important operation very often performed? The plant is turned out of the pot, the drainage which is enveloped by thousands of roots, is torn out in a rough manner, without any particular care being taken to inflict as little injury as possible, then innumerable active roots, which lay thickly round the sides of the ball, are torn and mutilated with a sharp pointed stick, which is thrust in amongst them over every half-inch or so of the whole surface, this being done with the intention of assisting the roots to enter the new soil; the plant is then transferred to its new pot, the requisite soil added, and the operation is completed to the satisfaction of the operator. Now, what is the condition of a plant so treated? It will either be just about to commence, or, in many cases, will have begun, to make its growth. But what is there to support the growth? All the best feeding roots, which, unquestionably, are those that lay at the outside of the ball, have been broken and lacerated, and are completely paralysed for many weeks, during which time the growth goes on; but under such conditions that the leaves are never more than half developed, the shoots are proportionately weak and puny, and the whole a prey to red spider and other insects, which seldom fail to attack a plant in a weak condition. The question may be asked, why are hard-wooded plants so treated? My reply is, simply from the difficult matter it is to "unlearn." Not only is such treatment as this too often taught by word and example, but instructions of a similar nature are conveyed by almost every treatise that has been written on the subject. I am not aware of a single publication that has appeared for the last twenty-five years on the cultivation of these plants that does not, more or less, advise such a practice. Why, again it may be asked, is this so? Because those who have written on their culture are practically unacquainted with their requirements. As far as my own practice goes, I like to complete this work of re-potting all hard-wooded subjects, with the exception of Azaleas, by the end of the present month, so as to get them established before the weather gets so hot as to necessitate the application of water at too short an interval after potting, and the admission of more air than is beneficial for plants of this description for some time after their removal. I usually proceed as follows. I first look over and select all that require a shift; examine the condition of the soil as to dryness, and give them a good soaking with water, so that they may not again require its application for as long a time as possible after they are transferred to the new soil. I allow them a day to drain, and then commence potting. In removing a plant from the pot it has already occupied, I never, if it does not come out easily, attempt to force it, but gently break the pot with a hammer; for, if there happen to be any inequalities in the shape of a pot, and the ball is forced out, a portion of the roots are almost certain to be injured, and it is much better to sacrifice a pot than a valuable plant. The plant is then laid down on its side on the potting bench and the drainage removed, care being taken not to mutilate the roots that enclose it any more than can be avoided; were it not for the absolute necessity, I should never remove the drainage at all, but, were it left, repeated shifts would necessitate pots so deep in proportion to their diameter that they would be very unsightly, or otherwise have no room for drainage at all. The plant is then transferred to its new pot, and the operator must be careful not to injure the side roots with the fingers in its removal. The soil is then put in a little at a time and rammed with the potting lath regularly until it is filled up to the surface, making the whole as solid as the ball of the plant. I have had a pot containing a hard-wooded plant so treated broken by accident within ten days after its removal, and at the time the roots were entering the new soil to an extent that would not have taken place in three months had they been mutilated, as so often done. Neither is the necessity for considerate treatment to those vital organs—the roots—confined to this section of plants; the latter are, however, more delicate and difficult to cultivate than any other subjects that come under the gardener's care. In my early gardening career, long before I had much to do with plants of this description, I was a good deal engaged in general fruit growing and forcing, and I then came to the conclusion that half the failures that arise in the cultivation of our leading fruits

are attributable to a want of condition in the roots or an insufficiency in their quantity, generally caused by bad treatment or no treatment at all—an opinion that I have not yet had any reason to alter.

T. BAINES.

Influence of the Stock on the scion in Variegated Plants.—A curious fact in connection with the Aucuba-leaved variety of *Passiflora quadrangularis* has been made known by M. Lemoine, of Nancy; grafted upon *Abutilon Thompsoni* and *P. Impératrice Eugénie*, a scion of this plant has communicated its variegation to both stocks, but only to such shoots as have pushed out above the spot where the graft was inserted. Of the shoots in which the variegation was most marked slips have been taken, and there are now two coloured varieties which may be perpetuated by means of grafting, and which it is the intention of M. Lemoine to bring out as soon as they have been produced in sufficient number. One remarkable circumstance noticed by M. Lemoine is, that the best variegated shoots have appeared upon a naturally green stock, whilst the scion, although still living, has never pushed growth, and lost, in fact, its two leaves at the end of two or three months. In each case the *Passiflora* never sent out variegated shoots below the graft. Another fact of the same kind is, that a scion of *Tacsonia Buchananii* was inserted in the same variegated *Passiflora quadrangularis*, and that this graft has now commenced to take up the variegation of the stock. In this case the scion has been affected by the distinctive peculiarities of the stock; in the preceding cases the result was of an entirely opposite character.

Pitcher Plants at Drumlanrig.—A few months ago I saw a collection of *Nepenthes* pitchers from Drumlanrig, and amongst these were two of *N. distillatoria*, which were also seen by Messrs. Veitch, who grow these plants so well; and they considered them to be the best they had ever seen of that species. I carefully tested these two pitchers, and each held considerably over a pint of water; indeed, so impressed was I with their extraordinary development that I took precautions to preserve them, and, only the other day, placed them in the hands of the museum authorities at Kew. I hope that Mr. Baines's remarks (see p. 233) will not deter cultivators from growing Pitcher plants in baskets; for I consider that it is a very successful plan to adopt, and this mode of culture is largely practised by Messrs. Veitch, who, it must be acknowledged, grow Pitcher plants well. *Nepenthes* like a very humid atmosphere, the nearer saturation point the better; and if, in addition to this, the surface of the peaty compost is covered with fresh living *Sphagnum*, there will be no occasion to fear that the roots will die off at the points. The finest plants of *N. Hookeri*, *N. sanguinea*, and *N. villosa*, that I ever saw were grown in baskets; and this mode of culture is to be recommended more especially in the case of the dwarf-growing kinds. I do not know how Mr. Thomson grows his big pitchers, but I know that the large free-growing species exhibit marvellous vigour when planted out. Mr. Speed had some fine plants of *N. Rafflesiana* and *N. Hookeri*, which produced large pitchers in the Amherstia-house at Chatsworth a year or two ago, and I believe these were planted out.—F. W. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Lapageria rosea from Seed.—I believe the best method of growing this beautiful greenhouse climber is from seed. It seems to be the easiest way of propagating it, and I mention the circumstance that those who are fortunate enough to have large specimens of this plant may do their best to obtain seed.—A. B. Y.

Different Degrees of Fragrance in Hyacinths.—Until this winter I was under the impression that all Hyacinths were equally sweet-scented. My attention being drawn to the subject, I find the greatest difference among all the colours; and as we only grow them for their perfume, and never trouble with the names, I would be very glad if any of your correspondents who have noticed this peculiarity in Hyacinths would give me a dozen names of each of the three colours—red, white and blue—among sweet-scented singles. For those who are overpowered by the smell of Hyacinths, it may be an advantage to know the names of those kinds that are devoid of the true Hyacinth perfume. In a pot of three reds before me, whilst two pinks are scentless, the perfume of a third, a rose-coloured kind, is delicious, the spikes of all being in perfection.—F. J. HORN, *Wardie Lodge, Edinburgh*.

Value of *Eucomis punctata* as a Hardy Window Plant.—I have a bulb, whose 2 feet flower-spike opened its blooms in the beginning of October, nearly six months ago, and these are almost as fresh as when first expanded. The plant is *Eucomis punctata*. It has stood the cold of the past winter in the window of a room in which there has been no fire. I grow many of them in pots, the persistency of the flowers making them very useful, and I should think almost indispensable to window gardeners. Although quite hardy, this plant is more suited for pot-culture. My treatment is as follows:—Shake out, divide when necessary, and re-pot in April, using sandy, rotten turf and decayed manure. Stand the pots during the summer in a hot sunny situation giving plenty of water; thus treated, in the early autumn every bulb shows a spike of flowers, when they are removed to the greenhouse or sunny window. The seed-vessel swells in the centre of the fragrant flower without the petals shrivelling or dropping, which serve as a calyx to the pod.—J. M., *Hawkechurch, near Axminster, Devon*.

REUTLINGEN SCHOOL OF GARDENING.

Of the many German schools of gardening, probably none has acquired a greater reputation, or turned out more able horticulturists, than that conducted by the eminent pomologist, Dr. Edward Lucas, at Reutlingen, in Württemberg. Since the opening, in 1860, it has been attended by over 700 pupils, representing, as regards nationality, almost every country in Europe, and even Africa and America; and, during the winter of 1872 and the summer of 1873, the students numbered seventy-one, many of them sent to the establishment at the expense of their respective governments, or of different horticultural and agricultural associations. Although pomology is, perhaps, the subject which occupies most attention in the school, and the one with which its name and reputation are principally associated; still, the course of instruction includes floriculture, Vine culture, market-gardening, dendrology, laying out of landscape gardens, and all other branches of horticulture; the same being taught by Dr. Lucas, his son, and two head, or superintendent, gardeners. For the preliminary and fundamental subjects, such as physics, geology, chemistry, &c., competent government school teachers are engaged. To meet the requirements of more or less advanced pupils, who have different careers in prospect, the institution is divided into two sections, a so-called superior school of pomology and horticulture, and a lower school of gardening, and the course of instruction in each occupies one year, or extends over three, according to the young man's previous experience and proficiency. In some instances, in the case, say, of schoolmasters and superintendents of parish or district plantations, even a year is often longer than could be spent at Reutlingen, and for that class of students Dr. Lucas has arranged a short spring course, especially adapted to their wants. As regards the future calling of the young men in the upper section, many of them intend to be landscape-gardeners, nurserymen, and farmers; whilst those in the lower division mostly become head-gardeners, nurseryforemen, florists, seedsmen, and fruit-growers. In addition to attending the different lectures, the students are expected to devote several hours a day to practical work, and indeed, under the direction of Dr. Lucas and his assistants, to perform (with very little outside help) all the operations necessary to the successful management of the orchards, nurseries, and gardens belonging to the school. The latter, which are cultivated with a view to profit, cover some 23 acres, and as the authorities of the institution, besides carrying on an extensive seed and fruit tree business, undertake the laying out of parks and pleasure-grounds, it will be seen that the pupil at Reutlingen has ample opportunity of familiarising himself with the details and routine work of his future vocation. As some remuneration for his services, at first 4d., and, after the first year, up to 1s. a day—making a total on the 305 working days of the twelvemonth, in the one case of about £5, in the other of something like £15—is deducted from his annual school fees. These, in the upper division of the establishment, amount to £27 per annum (inclusive of board, lodging, attendance, &c.) during the two first years, and to £16 during the third; in the lower section, to £24 and £17 respectively. A private bed-room costs from £5 to £6 per annum extra. No charge is made for instruction after the third year, should the student wish to remain beyond that time. Prizes and honourable mentions are awarded those pupils who distinguish themselves in the periodical examinations, and each youth on leaving receives a certificate giving an account of his behaviour, application, and progress. Should the certificate report favourably with respect to conduct and ability, it may be regarded as a sure passport to a remunerative appointment, the authorities of the school having at all times more applications for competent young gardeners and fruit-growers than they are able to satisfy. On leaving the institution,

the young men are encouraged to record from time to time their future horticultural experiences, making known, for the benefit of others, any new mode of culture, &c., they may be able to recommend; and some of the best articles in the "Gardeners' Year Book" and Journal of the German Pomological Society, edited by Dr. Lucas, have been contributed by old pupils, who now occupy important posts in all parts of the Continent. This useful interchange of experiences forms, as it were, a continuation of the discussions held one evening a week during the school term. On these occasions the students meet to compare the results of observation and inquiry; frequently a paper is read on some subject more particularly engaging their attention at the time; and Dr. Lucas, or one of his colleagues, is always present to give his opinion in any case of doubt or difficulty. For the benefit of any amateur gardener or fruit grower who may feel inclined to enlarge his knowledge of horticulture by spending a short time at Reutlingen, we may mention that outsiders, or occasional students—"hospitanten," as they are called—are admitted to any of the courses, can join in the botanical excursions, and, if they please, take part in the practical work of the school on payment of £1 4s. per month. For wet days, should the hot or greenhouses not attract there is an excellent library and collections of all kinds (carpological, geological, &c.) to fall back upon, and, in fine weather, the rich flora of the Black Forest and neighbouring Swabian Alps will be found to lure one in all directions. Beautiful spots and objects of interest within reach of Reutlingen are, indeed, so numerous, that the pupil, free to arrange his own plan of studies, would be under great tempta-

tion to make so-called "botanical excursions" a prominent feature of his programme. Supposing, on the other hand, the chief aim in his rambles is to see carried out on a larger scale the methods of garden, and especially fruit, culture, recommended in the lecture hall and practised as far as space will allow at the school, he need not wander far beyond the precincts of the town, as the more immediate environs of Reutlingen probably constitute (in the more restricted sense of the word) the most "fruitful" portion of the most fruitful

Reutlingen School of Gardening.

countries of Germany, viz., Württemberg. The accompanying illustration represents the principal building of the Reutlingen Institution, which will accommodate about fifty pupils. T. S.

Yew Poisoning.—During the last frost I had two valuable yearling colts in a 4-acre paddock. They had a warm shed to run in and out of, and as much hay as they liked to pull out of a rack; also a liberal allowance of crushed Oats, with bran and cut hay. They were seen well on the 30th December, at five o'clock at night, when they were fed, and both commenced to eat their corn as usual. Next morning, on going to them, one was found dead. I went to the paddock and found the colt just lying outside the shed on the snow. It had apparently dropped and died without a struggle, for the snow was not in the least displaced. The carcass was much swollen, and, when the head was severed from the neck, a large quantity of frothy brown-coloured fluid escaped from the trachea, and a black fluid blood oozed from the large vessels of the neck. The stomach was much inflamed, and moderately full of crushed Oats, bran, and cut hay (the evening feed), mixed with a quantity of Yew. Mr. Dawson, writing from Weston Park respecting the deer which were poisoned during the late frost, says:—"The animals got over the fence into one of the plantations, and ate the ends of the branches and the bark of the Yew trees. Three of the deer were found dead close to the tree of which they had eaten. The carcasses were warm and much swollen when we found them. The stomachs were full of Yew." My impression is that the activity of the poison is increased by the frost drying up the sap of the Yew.—"Veterinarian."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Parsnips and Carrots.—A full crop of Parsnips should now be sown without delay. This is a somewhat deep-rooting vegetable, and is much improved by the soil being deeply stirred. A bed of Early Horn Carrots should also be sown, as well as a little Turnip seed. For this sowing there is nothing better than the Red Topped American Stone, which is little inferior, in point of earliness to some of the more commonly-grown kinds, and possesses the desirable property of not running to seed when sown early, as some kinds do. Round Spinach may be sown now, either by itself or between rows of Peas; and in the latter position it will come in before it interferes with the gathering of the Peas.

Globe Artichokes.—The roots of Globe Artichokes, which have been protected in the usual way by litter laid round the crowns, and a slight ridge of soil covering them, should now have this protection removed; begin at one end of the row by first removing the soil, and then clear away the litter. If the plants are in good condition, they will now be pushing a far larger number of shoots to each crown than they can support, and they should, therefore, be removed, with the exception of some four or five of the strongest to each root. The best implement with which to take these off is an ordinary planting trowel; and, if the suckers are required for planting, they should be got off with a few root fibres, and at once be planted, four or five together, at distances of a yard apart in the rows, and with 4-foot spaces between the rows. This vegetable cannot bear a situation where there is any stagnant water. The roots in such soil generally die during the winter; it is necessary, therefore, to select a dry spot for it, and, further, it likes plenty of manure and deep cultivation. If the weather happens to be dry, give the plants a moderate watering, to settle the soil round the roots so as to get them established without delay. Plantations, made thus at the present time, will produce a good crop in the autumn, after the established beds have ceased bearing; and where this vegetable is held in estimation, and required over as long a period as possible, some should be planted each spring, even if it be necessary to remove a portion of the older stock to make room for them. Between these newly-planted Artichokes, a crop of Radishes, Spinach, or Lettuce, may be put in the ground, and these will come to maturity before being in the way.

Cauliflower and Lettuce.—Cauliflower plants from frames may now be planted out in well-dug, highly-manured ground—a planting trowel being used to remove them, in order that as much root as possible and a good ball of earth may be secured—planting them 2 feet apart each way, which, for this crop, will be ample space. Where Cauliflowers have been wintered under hand glasses, a portion of the plants must now be removed, some three of the strongest being left under each glass, and as these undisturbed plants advance in growth raise the glasses on bricks—removing them in the daytime, so as to give plenty of air, but keeping them over the plants at night. This not only protects them from any severe frost that may occur, but in mild weather brings them on quicker than would otherwise be the case. The plants that have been removed from the hand-lights will form a succession to those remaining. Should there be an indication of keen frost before these newly-turned-out plants get established there is no better protection for them than 8 or 10-inch flower pots placed over each. These pots effectually ward off the frost, and where the quantity grown is limited—as it is in an amateur's garden—the labour of removing and replacing them is small compared with the benefits to be derived from their use. Lettuce from frames and under the protection of south walls should also now be planted out in well-prepared and richly-manured ground—the richer the better—in order that they may be grown large and crisp, and also to prevent their running early to seed. Plant them 15 inches asunder in the rows, with the same distance between the rows. In taking them up use the planting trowel so as to check them as little as possible—the barbarous system of tearing up plants intended for re-planting, entailing, as it does, the certain destruction of their roots, should never be tolerated in a garden where there is any pretension to intelligent management. For this reason the fork or planting trowel should be used in taking up for re-planting even the commonest or least valuable vegetable—the little extra labour involved is as nothing compared with the gain. Lettuce or Cauliflower plants that have been sown in a little warmth must, as soon as large enough, be gradually hardened off and pricked out in frames, sufficient air being given them in mild weather to induce a sturdy growth.

Planting out Peas.—Peas that were sown in turves, tiles, or boxes, under the protection of frames or pits, having been previously well hardened by the admission of plenty of air, should now be planted out. Choose a sunny sheltered situation for them; and, as soon as they are planted, put small sticks to them, and if a few Spruce branches are at hand place them in the ground at the sides

(but not so as to weaken the plants by excluding light) in order to shelter them from cold cutting winds. Peas that are sown in the open ground should, as soon as they get fairly up, have the small sticks placed to them, for even the little shelter thus afforded has a marked influence on their growth. In some localities sparrows do not attack the Peas until the crop is fit to gather; in other places, these birds commence their depredations upon the points of every Pea as soon as it comes through the soil; and, unless means are taken to prevent it, completely spoil the crop. I have found nothing so effectually deter them as thick cotton thread, about the strength of a single strand ravelled from an ordinary spun dip candle-wick. Such material as this is easily obtainable in the manufacturing districts; the reason of its being better than ordinary sewing cotton is that it shows better on account of its thickness. Two or three threads, loosely hung on the sticks on each side of the row, and allowed to move in the wind, I have always found sufficient to keep them off; in some places it is even necessary to keep these threads on until the early crops of Peas are in bloom, or the sparrows will persistently nip out the points. Soot, dusted on the Peas, will, so long as it remains, prevent their depredations, but the first shower removes it, thus necessitating repeated applications, until, in its effects, it becomes poisonous to the Peas.

Tomatoes.—Tomatoes for planting out on walls, or similar places, should at once be sown in a well-drained pan, and the seed slightly covered with sifted soil in a little heat, either in a dung-bed already at work, or a Vinery that is started. The cultivation of this vegetable in the open air for the last two or three years has become very precarious in many places. It suffers from a disease very similar to the Potato disease; consequently, where Tomatoes are required, some provisions should be made for growing them under glass. They do well in pots, bush fashion, with a few sticks to support them, or planted out, and trained up to the roof as Cucumbers.

Herbaceous Plants.—There are numerous species of vigorous-growing herbaceous plants that soon impoverish the soil. Many of these summer and autumn blooming plants, such as Phloxes and Asters, may at once be taken up with advantage, the ground they have occupied well enriched, and then re-planted. If the plants have got too large—in which case the bloom is never so fine—they may at the same time be divided into two or more pieces. Spreading plants, such as Arabis and Alyssum, should now be regulated, any portions that have died off during the winter being removed, and a little fresh soil worked in amongst them, where the stems are getting bare. Remove Sweet Williams from the nursery-bed, to which they were transferred from the seed-bed last summer, to the situations where they are intended to bloom. These plants answer best when treated as biennials—the stock being kept up by yearly sowing—as they have a great tendency to go off at the collar after flowering. Now is a good time to make any additions required to the collection of herbaceous plants. Many of the principal growers of these keep a considerable stock of the best kinds in pots, and, by this means, they can be moved at any time without injury. Hollyhocks may now be planted. Where the dreaded disease attacks these plants, it generally makes a clean sweep in a few weeks. I should advise anyone, having a healthy stock, on no account to introduce any others amongst them; for, so far as I have heard, it has never made its appearance, except where there has been an introduction of plants from other stocks.

Pits and Frames.—It is time now to make a sowing of Melons. These can be raised in an existent Cucumber-bed, or similar place; the seeds sown (a couple each) in 48-sized pots, drained with some fibry turf; the pots half-filled up with good loam, pulverised by hand, or sifted. Just cover the seed, and fill up the pots with similar soil when the plants have grown a few inches high. Attend well to everything in this department that requires heat by applying the necessary linings, and keeping the whole well-protected with litter, to ward off the effects of the cold winds. Dahlia roots should now be put in, to start in warmth; for this purpose, nothing is more suitable than a dung-bed, with a bottom-heat of not more than 60°. The proximity to the glass in a frame of this description keeps the shoots much stouter, and in better condition for rooting when taken off, than when placed on the floors of Vineries, or similar places, where they are at a long distance from the glass, in consequence of which the cuttings are drawn up soft and weak. The seeds of annual Stocks and Asters should now be put in. They may be either sown in shallow pans, boxes, or in small pots, a few seeds in each of the latter. Keep them near the glass as soon as they are up; and be very careful in giving water to the Stocks, until after they have been transplanted, and have taken hold of the soil, as, previous to this, they are most liable to damp. Continue to strike cuttings of all bedding plants that are required, and bring this kind of work to a conclusion as soon as possible, so that the plants may gain strength, and get hardened off, before the time for turning out has arrived.

Houses.—If fire-heat was used a short time back as advised, the Vines will now be breaking; they will require the use of the syringe with more moisture in the atmosphere and the admission of less air—especially by closing early in the afternoon—than the pot plants like. Everything in the shape of bedding plants, that may have been wintered here, should be at once removed to pits or frames, and there sufficiently protected at night. Pelargoniums, intended for blooming indoors through the summer must also be removed, otherwise they become so weakened and drawn as to be spoilt. Fuchsias, Camellias, or any plants of this description, will be rather benefited by the treatment the Vines require. Do not cause a draught or cold current to pass through the house by giving air from the front, but confine its admission to the top. In the case of Vines that have been started early, and have now pushed their shoots to a considerable length, let them be tied down to the wires as soon as they are large enough, not allowing them to get too strong before being trained; stop the shoots at the second joint past the bunch. Syringe every afternoon as soon as the house is closed, until the bloom begins to open.

INSECTS INJURIOUS TO ROOM PLANTS.

THE family of plant-lice (Aphides) supplies by far the greatest number of the pests which infest plants grown in rooms, and, on account of their minuteness and remarkably rapid propagation, they are very difficult to extirpate. The peculiar formation of their mouth enables them to insert their proboscis into the cells of the tender parts of plants, and to suck the sap which should go to nourish growth. Discoloration of the bark and foliage, shrivelling of the leaves and shoots, and the formation of galls and excrescences, are the results of their ravages. The more tender and juicy the leaves and young shoots are, the more easily can the plant-lice pierce them and suck out the sap, and the faster the lice grow and multiply. Strongly-forced plants, which are kept too warm, or plants which do not get air enough, consequently afford a specially suitable nidus for these insects. The means both of preventing their devastations and, I may say, also of extirpating them where they have established themselves, consist in good culture, cleanliness, fumigation, sprinkling or washing with various liquids, and dusting with good insecticide powders. By good culture, which includes ventilation at the proper time, and keeping the plants in a position not too warm nor too far from the light, the plants are enabled to form strong healthy leaves which are less liable to be attacked by such insects than if they were less favourably circumstanced. By attending to cleanliness, all the decaying leaves will be removed on which the eggs and young of the lice often lie. When young shoots and leaves are much infested with lice, the best thing to do is to cut them off altogether and burn them, as, when so attacked they, even when thoroughly cleansed from lice, are usually distorted or even perish soon after. Plants from which the lice are to be removed should be shifted from among the other plants into a place where no other plants are near them. The stem-shoots and both sides of the leaves should be carefully brushed, and then washed with warm water and a sponge, to remove the "honeydew" with which the stems and leaves of such plants become covered.

Remedies.

The pot and the surface of the soil should, in all cases, be cleaned and thoroughly freed from all lice which may have fallen on them. This is the surest way of getting rid of the Woolly Louse (Coccus) and the Shield Louse (Aspidiotus), which do not appear to be much affected by fumigation. Moreover, when the Green-fly (Aphis) has been killed by fumigation the plants should be afterwards sponged over. Fumigation with tobacco is the only means that should be employed. Tobacco leaves of the cheapest kind should be placed in a vessel or fumigator on some live coals and allowed to burn for some time until the apartment is quite filled with a dense smoke. In rooms that are usually occupied, tobacco should not be employed, as its offensive smell will remain for weeks afterwards. The plants should therefore be fumigated in a small room set apart for this purpose, or under a bell-glass of suitable dimensions in a large room. When fumigation is employed against the Woolly Louse, Thrips, &c., the smoke should be made very dense and strong; the fumigation should also be repeated after a few days in order to kill any insects which may have been hatched

since the first fumigation; care should be taken not to fumigate more than is necessary. Light fumigation with tobacco may be used with most plants without injury to them, provided the plants are not placed too near the vessel containing the heated coals. Strong fumigations should not be employed with plants which have tender leaves or leaves covered with hairs, such as Heliotrope, Gesneraceæ, Melastomaceæ, as the total loss of the leaves is often the consequence of such treatment. The best thing to use in sprinkling is a solution of the genuine Persian insecticide mixed with water. About 3 ounces of this insecticide should be put into an ordinary glass bottle; the bottle should then be filled with spirits, and left corked for about eight days in a sunny window in a heated room. About a 200th part of this should be added to water warmed to about 123° Fahr., and sprinkled through a fine syringe on the leaves and stems affected. The evening should be selected for the operation, and the sprinkled plants should be placed for the night under a glass, or in a cellar, or covered with oil-cloth. The object of this is to prevent the rapid evaporation of the mixture; and, moreover, the fumes of the evaporating poison will destroy any insects which may have escaped the sprinkling. This is an excellent remedy against Aphis, Thrips, and Red Spider. When it is used against the Woolly Louse or the Shield Louse, one part of the mixture to fifty parts of water should be employed, and the sprinkling must be very thorough. A solution of black soap and guano may also be used, but it is not so effectual. Brushing and sponging is a still better plan than sprinkling, as the crevices and undersides of the leaves are more effectually cleaned in this way. In the case of the Shield Louse or Scale, it is the only sure method of removing them. After brushing, a sprinkling of strong liquid insecticide, or of a mixture of tobacco-water, potash, and black soap will be useful; the plants so sprinkled should be washed with clean water next day. The last remedy mentioned is dusting with insecticide powders. When these are used, the plants should have been previously sprinkled with water, which will retain the powder better and prevent its being scattered. The principal kinds used are the Persian insecticide, tobacco-powder, lime, wood and peat ashes, gypsum, and, for the Woolly Louse and the Scale, powdered sulphur. Of Aphides some are winged, and others not. The common Green-fly infests Carnations, Fuchsias, bulbous plants when forced, and other room-plants, and may, like other kinds of aphis, be extirpated by a light fumigation, or by other means already described. The Water-lily Aphis (Nymphæa) infests Alisma, Nymphæa, and other water and bog plants. In the aquarium it attacks Limncharis, Pontederia, and similar plants. The remedy is to sprinkle the plants with some of the insecticide mixtures, or to fumigate lightly, covering the aquarium with an oilcloth for one night after the operation. The Rose Aphis (*A. rosæ*) is bright green in colour. It infests the under-surfaces of tender-leaved plants, such as variegated Caladiums, and many other stove and greenhouse plants. The Olive-green Aphis (*A. olivacea*) chiefly attacks the young shoots, leaves, and buds of hard-leaved plants, such as Camellias and Palms, which, when they are numerous, they cover with an unsightly incrustation. The Pelargonium Aphis confines itself to Pelargoniums and other tender-leaved green-house plants. The Orange Aphis infests the young shoots and the under-surface of the young leaves of the Orange tree. The common Coffee or Woolly Louse (*Coccus adonidum*) can only be extirpated by strong and repeated fumigations. The plants should also be cleaned and sprinkled with or dipped in some of the liquid insecticides already mentioned. When cleaning the plants, all tyings of bast-mat, &c., and the sticks to which the plants are fastened, should be removed, as well as all loose chinky bark from the stems, as these are generally full of eggs.

Scale Insects.

Of the Scale or Shield Louse (*Aspidiotus*), it may be mentioned that only the wingless insects run; the older ones, whose legs have been gradually absorbed into the body in the course of their growth, remain fixed to the spot where their proboscis has penetrated the plant. Over the insect thus fixed a mussel-shaped scale is produced by a secretion from the body. Under cover of this scale the insect lives, and lays its eggs. The young larvæ, when hatched, creep from under the scale and

spread themselves over the plant. The Oleander Scale infests hard-leaved greenhouse plants (often thickly covering the stems and the leaves), such as Nerium, Arbutus, Magnolia, Azalea, &c. It especially attacks Oleanders which are kept in too warm and dark a position. The only way to remove it is to clean the plants with a brush, and then wash them with a mixture of tobacco-water, potash, and black soap. A thick dusting with sulphur is generally efficacious, but not so much so as the means just named. These insects spoil the appearance of the plants; no time, therefore, should be lost in removing them when they show themselves. Other species of this genus, which must be extirpated in the same manner, are the Rose Scale, the Cactus Scale, the Laurel Scale, the Palm Scale, the Pseudo Scale (*Lecanium*), Pine-apple Scale, and the Nightshade Scale, which infests *Cestrum*, *Solanum*, and tender-leaved hot-house plants. The Thrips, as most cultivators know, has a well-developed feeding apparatus. It resembles the plant-lice in living by suction, and it propagates itself by means of eggs. The Brown Thrips is small and slender, scarcely a line in length, and, when full grown, is of a brownish colour. It infests the under-surface of the leaves of *Dracæna*, *Cordylina*, and many other favourite room-plants, and is one of the most destructive of small plant pests. When leaves are attacked by it, they lose their colour, and become whitish in spots or entirely so, and, moreover, are dotted with small black points, arising from the excrements of the insects. The best remedy is to sprinkle or dip the whole plant in some liquid insecticide. A slight fumigation, or frequent sponging, should also be resorted to. The full-grown insect is very lively, flies fast, and spreads quickly. The eggs are hatched in the space of twenty-four hours, and the larvæ remain together for the first few days, after which they soon spread over the whole plant. The Black Thrips resembles the last in its habits and shape, and requires the same remedies. It is slender, of a pale black colour, and covered with rough hairs.

Spiders, Woodlice, and Worms.

Among Spiders, the only species injurious to plants are the small kinds which belong to the genus *Acarus*. Only one species infects plants grown in rooms. This is the Red Spider; it is a small spider-like insect, with eight legs, and is scarcely visible to the naked eye. Its colour is reddish, yellowish, or brownish, with a few more or less confluent dark-brown marks on both sides. It infests various plants, sucking the sap from the leaves, which lose their colour in consequence. The white-spotted appearance of the leaves, and the cobwebs which these insects produce, are signs of their presence. The drier the air of the apartment the more favourable is it to the production of these pests. They attack soft-leaved and hard-leaved plants alike, and succulents of all kinds. The best remedy is to wash or dip the plants in liquid insecticide, and the plants should be well sponged some days afterwards. As this insect spreads very rapidly in a dry atmosphere, it is an excellent plan to dip the plants in water from time to time. The Woodlouse, which preys on the young shoots of tender plants, may be trapped by means of hollowed-out Carrots or other roots, or dry Bean-stalks, or by fastening two boards together with a small space between them. They will creep into these, and, when the traps are examined every morning, may be shaken into boiling water. Slugs are sometimes troublesome in plant-cases. Where traces of them are observed, they must be looked for and caught at night with a light. Of Worms the only hurtful kind is the common earth worm; it infests the balls of pot plants and spoils the soil. It also stops up the drainage-hole in the bottom of the pot, so that water cannot escape, and the soil becomes sour in consequence. The presence of worms in a pot is indicated by the accumulation of their casts on the surface of the soil. When a pot is suspected of containing worms, it should be tapped smartly with the hand; the worms in alarm come to the surface, when they should be seized at once, otherwise they will quickly retreat to the centre of the ball, so soon as they feel the least touch. If they cannot be dislodged in this manner, the ball must be carefully removed from the pot and examined, but not broken. Should this also fail, then water the pots with water heated to 123° Fahrenheit, or with

an infusion of tobacco, Walnut leaves, or with liquid insecticide, or a solution of guano. This will send the worms either to the surface or to the sides of the pot, when, by lifting out the ball, they may be caught and killed. If the pot is placed half-way in a vessel of water heated to 123° Fahrenheit, it will be found the surest way to send the worms to the surface.

M.

IVY-CLAD TREES.

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

Few will deny that a forest of Ivy-clad trees, at any season of the year, but more particularly during the winter months, when all deciduous vegetation may be said to be at rest, is an exceedingly beautiful and picturesque sight. To encourage the growth of Ivy amongst good and stately trees is very questionable, unless with a view to ornament. In many districts in Scotland I have seen the Ivy almost completely covering very large trees, with only some of the terminal branches protruding, in a healthy condition, through the luxuriant growth of this rapacious intruder. In time, however they also fail, and the injured stems are seen supporting the Ivy long after the vitality of the tree has been lost. Heavy loamy soil is generally very favourable to the growth of Ivy, particularly in sheltered situations. In such localities the Ivy runs freely on the surface of the ground, and ascends the neighbouring trees, preferring in most cases the deciduous kinds. I cannot call to my recollection any instance of Ivy growing on healthy evergreen trees and shrubs (except in the case of the Yew), or on any of the Pine tribe. The Oak, Ash, and Elm, seem to be its chief favourites, and, I may add, its chief victims. In some parts I have seen the Ivy stems all cut round on the surface of the ground, for the purpose of killing it, in order to prevent injury to the tree. In such cases the aerial or stem roots have generally taken such a hold of the living bark that severing the stems has but little effect. Not so, however, with Ivy on walls; if cut at the base it will ultimately die, and can be removed in large brown flakes. When the Ivy assumes a climbing or free-growing character, the leaves possess a more entire shape, and in this condition flowers and fruit are abundantly produced, which is not the case when it is seen running on the level ground, unless it comes in contact with old stone walls or decayed tree stumps. The variegated varieties are very numerous, and many of them rather pleasing. In pot culture (trained) they produce an excellent effect, but when planted against a wall they do not get into that free-growing state characteristic of the green varieties. When grafted or inarched—and this is more particularly the case with the gold and silver varieties—their pendent branches have a pleasing appearance amongst the green varieties, and when so treated they grow much more freely than they do on their own roots. The green varieties are also numerous, but for a speedy wall covering, the variety known as the Irish palmate-leaved is decidedly the best. Besides covering the bare trunks of trees with perpetual verdure, this kind is admitted to various uses in the decoration of our gardens, one of which may be seen at page 265. Its stems cling firmly, by means of little rootlets, to whatever they come in contact.

Moles and their Worm-stores.—In a tract of meadow land in Norfolk, which lies below the level of a tidal river, and which is, therefore, preserved from being submerged by artificial embankments, the mole is not infrequent, although he is regarded by the occupiers with great disfavour. In addition to his ordinary sin of making the Grass-land difficult to mow, he has an ugly trick of boring into the river walls; and, by loosening the sods which hold these walls together, imperils the walls themselves. Mole-catchers are, therefore, in great request, and a few minutes spent in company with one have taught me a lesson on the mole's history which was quite new to me. March is the mole's breeding month; and, in preparation for the appearance of the young ones, stores of fresh meat, in the shape of worms, have been laid up under hills, larger than the ordinary mole-hills, but in the open marsh, which an experienced eye readily recognises. The mole-catcher (in whose company I found myself accidentally) is employed to poison moles, and the food in which he puts his poison is the common earth-worm. Sooner than spend his time in digging for these on the upland, he had come down

IVY ON TREES.

to the marsh to rob the mole's larders, and he hit on these with the sagacity of a terrier sniffing at a rabbit's burrow, and did not open a hill in vain when I was with him. He chose the largest hills which were on the highest spots on the marsh, and opening one in my presence, he laid bare a round cavity, the sides of which were beaten hard by the mole, so as to prevent the worms from attempting to pierce their way out. Inside this there was nearly a quart of fine worms, quite free from any admixture of soil, each worm apparently tied up in a coil or knot, yet all alive. Upon being dragged out of the place in which they had been stored, the worms began to wriggle away; but the mole-catcher put them into the box he carried, and took away his prize. Is this habit of the mole generally known among naturalists? It seems to argue a reflective faculty, great as in the beaver, that the mole should prepare a prison in which worms can be kept alive.—"Field."

THE GARDEN IN THE HOUSE.

EXOTIC FERNS FOR HOUSE DECORATION.

SOME recommend that Ferns, at the annual potting, should be shifted into larger pots than they previously occupied; and that, in performing the operation, the ball should be reduced only where the roots are decayed or the soil effete, but not be otherwise disturbed—a practice which also necessitates shifting into pots a size larger, till both plants and pots become unwieldy. Where Ferns are grown for specimens, this practice is perhaps correct enough; but where, as with most people, the object is to have as many plants as possible in a limited space, and none of them in large pots, a somewhat more summary process has to be adopted. Ferns for house decoration do not require potting more than once annually; consequently, when they come to be shifted in spring the roots are considerably matted. To reduce the balls then by the pricking process, *i.e.*, with the point of a label, is tedious and lacerates the roots unnecessarily. To avoid these evils, and in order to reduce the balls sufficiently to get them back into the same sized pots again, and at the same time to admit of a considerable supply of fresh soil, we simply take the plant out of the pot and with a large carving-knife fearlessly shave a thick slice of the ball off all round, taking a proportionately thick slice off the bottom; and the root-pruning is finished. The plant is then potted moderately firm, in a pot pretty well drained. I do not think there is a better way than this of dealing with matted roots. You get rid of them at once, and, the cut being clean, the main roots soon push fresh rootlets into the new soil, and start a new growth of fronds. All our Ferns are treated in this way, and I do not think we ever lost a plant by this practice. Sometimes, when such as the *Gymnogrammas* get two stems, the balls are cut through the middle, the two halves rounded with the knife, and potted separately in smaller pots for a succession, the older plants being thrown away when room is required. No Fern should be potted in a very dry state, or the chances are that the ball will never get soaked afterwards; therefore, when they are dry, the balls should always be thoroughly steeped previously to potting, by simply setting them in a tub of water kept ready for that purpose. This is the only way to soak a ball that has got thoroughly dry through being overlooked in the watering. For similar reasons, newly-potted Ferns should always be kept well watered after potting, till the new roots begin to get hold of the fresh soil. Ferns, though by no means aquatics, like moisture both at root and top, and thrive amazingly around the edges of a tank, or just above the water, set on inverted pots to keep the roots from contact with it. Though no plants seem to stand extremes of temperature so well as Ferns, I have always found that such as the Mexican and New Holland varieties make by far the healthiest growth in a shady intermediate-house. They will grow well enough along with the tropical kinds; but the foliage is weaker, and, in the case of the Maiden-hairs particularly, the fronds cannot be compared with those developed in cooler quarters for hardness of texture and dark green colour; hence, the latter are far better for decoration, for bouquets, head-dresses, &c., because they stand exposure better. *Adiantums* grown in hot stoves are almost worthless for cutting from, as they wither almost immediately in warm rooms; but hardy-grown fronds will endure a night's bad usage well, and will take no harm for a week or more, on a plant in a vase. It is always well to have a good proportion of Ferns among plants for house-furnishing, and plenty in small pots, along with *Lycopods*, &c. No kind of foliage is more generally adaptable to all kinds of situations and circumstances than that of the Fern; and, when the plants are in small pots, they are always ready for all the emergencies when packing or backing up is required. The common *Lycopod* is a host in itself. A good way to grow it is in common pots or saucers, with a hole in the bottom. It can then be turned out, and used for covering surfaces expeditiously.

TREES AND SHRUBS.

NOTES ON CHESTNUTS.

The Sweet Chestnut.

THE Sweet or Spanish Chestnut, *Castanea vesca*, is one of the commonest and most valuable trees of Southern Europe, where its Nuts form the chief sustenance of a large portion of the inhabitants. The Chestnut is a near relative of the Beech; and, indeed, under the name of *Fagus castanea*, was considered by Linnæus to belong to that genus. The native country of the Chestnut appears to be in the regions around Kastanea, an ancient city of Pontus, whence the tree probably derives its botanical name. Extensive Chestnut forests still exist in that neighbourhood, and many of the trees are remarkable for their great size and age. The Chestnut was introduced into Greece about 504 B.C., and rapidly spread over that country, where, at the present time, it forms large forests. In the time of Julius Cæsar, during the Roman wars in Asia Minor, it was transplanted to Italy, where it soon became highly esteemed, not only for its excellent timber but also for the nourishing and wholesome food obtained from its Nuts. Greek and Roman writers frequently allude to the tree, and especially to the Nuts. Pliny describes eight varieties of Chestnut as cultivated in Italy in his time; and Virgil, on several occasions, speaks of the Nuts as held in high favour by the country people:

Ripe Apples and soft Chestnuts have we there,
And Nuts abundant to supply our fare.

The culture of the Chestnut was introduced and fostered by the Romans wherever their far-reaching sway extended, and thus it became acclimatised in France, Spain, Germany, and Northern Africa. To judge from some specimens of this tree which, at present, exist in England, it must have been very early introduced into these islands—probably during the Roman occupation. It has also been transplanted to America, where it has become fully acclimatised and flourishes vigorously, especially in the Canadian province of Quebec. In Germany there are extensive Chestnut forests, and the Nuts ripen even upon the slopes of the Harz Mountains. In France, 1,250,000 acres are planted with this valuable tree. The best French Chestnuts are grown in the departments of the Oise and Rhone, where they are to the poorer inhabitants what the Potato is to the Irish peasantry. Large forests of Chestnuts clothe the hilly and mountainous regions of Spain and Portugal, where the mild climate and dry light soil is well suited to its requirements. Some of the finest Chestnut forests in the world are found in the island of Corsica, where the rich and lovely central zone, which lies between the low marshy coasts and bleak snow-clad mountain peaks of the island, is known as *La Castagnicia* or "The Chestnut-land." The Chestnut grows in sheltered situations in all parts of England, Ireland, and the south of Scotland, but the Nuts do not ripen north of the Thames. The finest English Chestnuts are found in Sussex and Devonshire. The Chestnut thrives best in dry, airy situations, upon granite or sandstone formations, and with an eastern or western exposure; it seldom reaches maturity upon chalk or limestone formations, or in a damp heavy soil. The roots are strong, penetrate deeply into the earth, and require a considerable depth of soil. In point of climate, the Chestnut is not so hard to suit as in point of soil; in this country it loves a rich, warm loam and a dry sandy sub-soil. The highest elevation at which the Chestnut is found is upon Mount Etna, where there are some fine trees at a height of 3,800 feet above the level of the sea. Upon the Alps fine strong trees grow at an altitude of 1,800 feet. The young roots are very susceptible of frost, but when the tree has once obtained a firm hold in the soil it can withstand very severe winters. The seeds, however, should never be sown in autumn, as the germinating power is apt to be destroyed by the frosts of winter. The best course is to place the Nuts intended for seed in layers of sand in a dark cellar, and then to plant them out in spring, as soon as all danger from frost is gone. The best seeds for planting in the British Isles are those produced in Devonshire; and next to them German seeds may be recommended. French and Italian seeds do not produce good

trees in this country. The best German seeds are grown in the valley of the Neckar, and in the vicinity of Heidelberg. The trees produced from seeds yield only small Nuts, and to obtain good fruit they must be grafted upon Pear, Apple, or Cherry trees. A very fine ornamental tree may be obtained by grafting the Chestnut on the common Beech. The timber of the Chestnut is not inferior to that of the Oak, and lasts a long time in water, and under or above ground. It is extensively employed for mill-timber, bridges, posts, stakes, hop-poles, and casks. Trees fifteen years' old make splendid hop-poles, 30 feet long and 3 inches thick. The bark is firm, smooth, tough, and very useful to tanners and dyers. The greatest value of the Chestnut, however, is in its Nuts, which ripen in September, and which are largely consumed as an article of diet upon the Continent, in Western Asia, and in Northern Africa. In Corsica, the peasantry subsist almost entirely upon Chestnuts and goat's milk, and the guests at a Corsican wedding-feast are regaled with these Nuts, prepared in twenty-two different ways. In Sardinia, 87,500 cwts. of Chestnuts are annually consumed; and, in France, the produce of the vast Chestnut forests, which form a broad belt across the south-east corner of the country, does not meet the native demand. The Green Chestnuts of Limousin are considered to be the best variety of this fruit. About 70,000 bushels of Chestnuts are annually imported into Great Britain from the Continent.

Geographical Distribution.

Chestnuts are very widely distributed over the northern hemisphere. North America possesses several indigenous species, of which the best known is the Chinquapin Nut (*Castanea pumila*). This tree seldom attains a greater height than 30 feet, and has a handsome shrub-like appearance; the branches are numerous and slender, and the foliage dense and of a bright green colour; the Nuts are small but very sweet and pleasant. This tree thrives well in this country, and is a very handsome object in parks and pleasure grounds. It both grows and looks best when planted in an open airy situation. There is also another species (*Castanea chinensis*) which is found in China, Burmah, and Assam. It is a large tree, and is highly esteemed for its timber. The blossoms of this species are exceedingly pretty; and, when in full blossom, the tree looks as if hung with beautiful yellowish-white tassels; the foliage is also very handsome, and the Nuts are very sweet. Several species of Sweet Chestnut are found in Java, Borneo, and Sumatra, but little or nothing is known of their culture or the value of their fruit and timber. Some of the largest trees in the world belong to this genus. The most celebrated is in Sicily—the *Castagna di Cento Cavalli* of Mount Etna; the trunk of this tree is composed of seven amalgamated trunks sprung from one common root. It measures 180 feet in circumference at the base, but only one of the trunks still shows signs of vitality. Close beside are two other Chestnuts, respectively 70 and 64 feet in circumference. These trees are calculated to be 5,000 years old. In the village of Millet, near Sancerre, in France, there is a Chestnut whose trunk is 48 feet in circumference at a height of 5 feet from the ground. Upon Mount Cenere, in Tessin, there are Chestnuts which must have been saplings when Tell was a boy. The oldest English Chestnut is that at Tortworth, in Gloucestershire. The following description of this tree is appended to a picture of it executed in 1772:—"The east view of the ancient Chestnut tree at Tortworth, in the county of Gloucester, which measures 19 yards in circumference, and is mentioned by Sir Robert Atkins in his history of that county as a famous tree in King John's time; and by Mr. Evelyn, in his "*Silva*," to have been so remarkable for its magnitude in the reign of King Stephen (1135), as then to be called the great Chestnut tree of Tortworth, from which it may reasonably be presumed to have been standing before the Conquest (1066)." The age of the Chestnut varies from 360 to 626 years, so that at the age when the Oak is of most value as timber the Chestnut is utterly worthless.

The Horse Chestnut.

The Horse Chestnut (*Æsculus hippocastanum*) is a very different tree from the Sweet Chestnut. It belongs to the genus *Æsculus*, and is a native of Asia, whence it was intro-

duced into Europe by the Turks. Gerarde thus explains the origin of the name:—"They are called *Equina castanea*, or Horse Chestnuts, because the people of the East countries do with the fruits thereof cure their horses of the cough, shortness of breath, and such like diseases." The Horse Chestnut was first introduced into England in the reign of Queen Elizabeth, by Mr. Tradescant, who cultivated it in his garden at South Lambeth. The Horse Chestnut is a very handsome tree, gives a pleasant shade, and forms an imposing and picturesque object in the landscape. In this country it rarely exceeds 60 feet in height. In North America there are several indigenous species of this tree; it there attains a height of 80 or 90 feet, and a circumference of 15 feet. The bark of the Horse Chestnut possesses strong febrifugal qualities, and is valuable for tanning and dyeing purposes; it also yields a useful drug called *Æsculin*. The timber of this tree is much inferior to that of the Sweet Chestnut; it is best suited for the construction of flooring and packing-cases. It has been calculated that 100 lbs. of Horse Chestnuts contain as much nutriment as 150 lbs. of hay; and in France, Switzerland, and Turkey, it is customary to feed cattle, horses, sheep, and goats, upon a kind of meal prepared from the Nuts. Excellent charcoal and potash are obtained from the wood of the Horse Chestnut, which also makes good fuel. The Horse and Spanish Chestnuts suffer less than almost any other tree from the ravages of insects. One of their most formidable enemies is *Bombyx æsculi*, which deposits its eggs upon young trees. The grub, on emerging from the egg, eats into the pith of the tree, and renders the timber useless. This destructive insect also attacks Apple and Pear trees, Oaks, Alders, Beeches, and Walnuts.

JOHN HUTCHINSON, M.A.

MEASURING GROWING TIMBER.

To those unaccustomed to measuring growing timber, it will appear a laborious undertaking to measure and value two or three thousand growing trees. It is not so difficult, however, as many imagine, and an expert hand will easily measure from 800 to 1,000 trees in a day. We keep a staff of six or eight labourers to show the lots and assist in measuring the timber, and, a few days before the sale, the whole of them are employed with different parties. Each timber merchant requires two assistants; one carries a long pole marked in feet, and the other a leather strap, which indicates the side of the square. In going to work, the man with the pole declares the height of the tree in feet; the man with the strap the side of the square in inches; and the timber merchant refers to his sliding rule for the contents. The measurer has to allow an inch, and sometimes more, for the taper of the tree from where the girth is taken, to the centre of the portion he is measuring. Of course, this is measuring with a centre girth; but an experienced measurer never goes higher than half the circumference of the butt, and adds the number of feet he considers the tree contains above that point. All these things are puzzling to a beginner, but it is astonishing how accurate an old practitioner's work is. Some contend, says Mr. A. Peebles, in the "*Arboricultural Society's Transactions*," that it is impossible to give an approximation of the contents of growing timber by means of a pole and strap. They argue that an experienced judgment and practised eye are more to be depended upon. If those using the pole and strap were to discard the eye and judgment, there might be some force in this reasoning, but as they do not, the whole argument falls to the ground. I speak from experience when I assert that there is seldom a difference of 5 per cent. in the measurements of the various purchasers, and when the lots are afterwards tested, most of them are actually within 5 per cent. of the truth.

NEW HYBRID AUCUBAS.

SEVERAL years have elapsed since I offered a few suggestions regarding the best means of improving the *Aucuba japonica*. At that period little more than theoretical knowledge was at our command, and it was only the hybridist who could with confidence predict that great success was in store for those who were prepared to work with patience and judgment. Contrary to the reasonable hope that by this time the ornamental capabilities of this beautiful shrub would have been largely developed, apparently but little advance has been made either by nurserymen or amateurs to improve the fine properties of the *Aucuba*, which is, nevertheless, eventually destined to occupy a prominent position as a table, greenhouse, and border

decoration. Indeed, it may safely be assumed that it will become a formidable rival to Crotons, Dracænas, and other fine-foliaged plants, for even now a few of my choicest productions do not compare unfavourably with the best of them. My present hope is, if possible, to awaken the energies of amateurs by showing them that a satisfactory share of success has attended my own efforts, and by assuring them that they may easily obtain great results. With this object I propose briefly to refer to those varieties from which my early seedlings were raised (some of which are very good); afterwards I shall make a few explanatory remarks, and then conclude with a description of some of my best seedlings. The latter will necessarily be imperfect, because the *Aucuba* requires several years to attain its permanent character, and many of my best productions are very small. My first attempts at seeding were made with *maculata*, *longifolia variegata*, *longifolia aurea variegata*, *salicifolia*, *limbata*, and *longifolia viridis*, fertilised with *picta*, *bicolor*, and *maculata Sieboldii*. The first four-named varieties are still useful, though the rest have long since been discarded to give place to my own seedlings. Many improved varieties might be raised by those who are satisfied to trust to accidental fertilisation by planting a number of plants of *maculata* in a favourable and isolated situation in company with a few highly-coloured male plants. *Salicifolia* merits special notice; its long, narrow, dark green foliage and large scarlet berries, are so attractive as to place it before all other green *Aucubas*; and if, in July, it is root-grafted upon a seedling just below the seed leaves, it will fruit the following spring and form a charming object, possessing the advantage of rarely making a growth below the junction of the graft. Large-leaved varieties are very beautiful and valuable for out-door purposes, but they fruit sparingly, a defect which renders it desirable to encourage medium and small-leaved seedlings, which, if possessing finely-marked foliage and free-fruiting properties, are more suitable for pot culture. Narrow-leaved kinds are so distinct in form, and bear fruit so profusely, as to make it important to induce the increase of this class, though it will require many years before they can come into general notice, on account of the necessity of having to raise them chiefly from green-leaved plants fertilised with the broad-leaved section. As an example of this difficulty I may mention that, having decided to raise coloured seedlings of the *salicifolia* and *longiflora* type, the progress to that end was so tedious that, from about 1,200 berries of narrow-leaved sorts, I have only raised four finely-marked plants of *salicifolia*, and under a score of *longifolia*; but, it may be added that these seedlings possess such distinct and novel properties as amply to reward me for my labour, and this break will probably introduce a highly valuable class. Occasionally *Aucuba* berries contain two seeds; twice, when this has occurred, two plants have germinated, which, in consequence of their close proximity, have become naturally grafted. Taking a hint from this circumstance, I have tried and

succeeded in root-grafting a seedling before it had made a true leaf. The following are such of my seedlings as seem worthy of notice, viz.:—*Viridis caudata*, a dwarf compact-habited plant, with small and slightly caudate leaves; *viridis fasciata*, foliage various, green, dense, obovate, occasionally auriculate, fruit cylindrical and abortive, stem and branches fasciated; *marginato variegata*, foliage small, slightly caudate, irregularly variegated with white on both surfaces of the leaves, has a tendency to become margined; *variegata intermedia*, a fine variegated male; *variegata tricolor*, a very interesting variegated male, showing a curious combination of green, yellow, and creamy-white; as this seedling has only five leaves it will probably improve considerably; *lato-aurea variegata*—I have a fine

male and female specimen of this grand variety, the leaves are large and broad, beautifully marbled with yellow and green; *marmorata aurea*, a fine yellow marmorated male, foliage small; *maculata tricolor*, a male, colours rather indistinct, but will probably serve to produce seedlings of better defined shades; *salicifolia maculata*, female, foliage dark green and yellow, very distinct; *salicifolia maculata* and *marmorata*, three distinctly different and highly promising seedlings; *longifolia maculata* and *marmorata*, six or more new varieties; *longifolia maculata intermedia*, a bold-leaved and promising seedling. During the next month I hope to be able to supply my friends with pollen, of a quality such as they cannot obtain elsewhere, and as it is possible that after their requirements have been met there may still be a small surplus, I shall be most happy to distribute it amongst a few amateurs, if they are disposed to try their hands at fertilisation.

A. CLAPHAM.

Ramsdale Bank, Scarborough.

Ivy in the Botanic Gardens, Montpellier (see p. 263).

Exhausting Effects of Close Pruning.—During the past autumn we saw at Blythefield a very remarkable illustration of the effect of close pruning on the constitution of a plant, as compared with a free extension of growth. In one part of the pleasure grounds was a Hornbeam hedge of considerable age, and about 8 feet high, presenting the usual appearance of a hedge of this kind, the individual trees bearing a multitude of slender twigs. From some cause or other the end tree of this line of Hornbeams had been allowed to grow unmolested,

and while the constantly pruned plants were no thicker than one's wrist, the freely grown tree was a fine umbrageous specimen with a stout trunk, and a head at least 40 feet high. It formed a capital illustration of the truth, that constant repression is exhausting, and the accidental juxtaposition of the hedge and the tree brought out strongly the different effects of the two systems of pruning.—“Florist.”

Preservation of Form in Flowers and Leaves.—A very ingenious application of electro-metallurgy has recently been brought before the notice of the Society of Arts. It consists in the application of a coat of silver, by means of electro-deposition, on natural leaves and flowers. By this means very delicate ornaments are produced, since the precise form and texture of the natural leaf are preserved under the thin silver film. The special process by which these results are obtained is the invention of Mr. Denton.

THE KITCHEN GARDEN.

NOTES ON LAST YEAR'S POTATO CROP.

THE summer of 1874, though generally very favourable to the Potato crop, was not one that suited me. My land (situate in Nottinghamshire), being a light loam with gravelly sub-soil, suffered considerably in such a dry season as the last. From this cause, and the injury done by the frosts in May, especially those of the 17th and 18th, my crop of "earlies" was practically worthless. The following table shows the result of the whole crop:—

	Weight of Seed.		No. of Sets.		Distance apart.		Date of Lifting.	Weight of Crop.
	Whole Sets.	Cut Sets.	Whole.	Cut.	Rows.	Sets.		
	lbs.	lbs.			feet	in.		lbs.
1. Racehorse	3½	—	36	—	2	9	Aug. 5	15½
2. Mona's Pride	7	—	60	—	2	9	Aug. 5	30
3. Ashleaf	7	—	73	—	2	9	Aug. 5	29
4. King of the Earlies	7	—	44	—	4	12	Aug. 5	50
5. Early Rose	7	—	48	—	2½	12	Aug. 12	76½
6. Early Goodrich	3½	—	23	—	2½	12	Aug. 5	11
7. Bresee's Prolific	3½	—	16	—	2½	12	Sept. 3	6
8. Myatt's Ashleaf	7	—	53	—	2½	10	Aug. 5	23
9. Prince of Wales' Kidney	2¾	—	20	—	2½	10	Sept. 5	13
10. Berks Kidney	3½	—	32	—	2½	10	Sept. 5	18½
11. Sedilla	7	—	64	—	2½	12	Sept. 11	58
12. Brailsford's Seedling	4	—	67	—	2½	12	Sept. 12	44
13. Peach Bloom	2½	—	19	—	2½	12	Sept. 12	28
14. Late Rose	6	—	61	—	4	15	Sept. 16	185
15. White Don	6	—	48	—	4	12	Oct. 1	90
16. Harbinger	7	—	68	—	2½	10	Oct. 19	74
17. Oxfordshire Kidney	14	—	103	—	2½	12	Oct. 19	193
18. Queen	6	—	60	—	4	12	Oct. 20	172
19. Model	14	—	69	—	4	15	Oct. 21	162
20. Paterson's Victoria	7	—	51	—	2½	12	Oct. 20	64
21. American Red Seedling... ..	7	7	22	22	4	15	Oct. 30	{ 71½* 72† 119*
22. Red Flake	3	3	21	21	4	15	Oct. 30	{ 97† 142*
23. Red-skinned Flour-ball ..	7	7	38	38	4	15	Oct. 31	{ 142† 160
24. Wood's Scarlet Prolific ...	6	—	38	—	4	15	Oct. 31	

There was no disease, with one exception. Late Rose was lifted in fine dry weather, and came up a very fine, large, and level set without a symptom of disease. They were so inviting that they were taken into use at once, and fortunately; for about three weeks after they were dug disease appeared, and the whole became affected so quickly that in another three weeks it took a peck-basketful to provide a dish for the table. This is the only disease I have had. The whole crop was treated as far as possible in the same way. No manure was used except a light dressing of old stable litter early in the spring. The planting began on March 7th with No. 1, and was continued throughout the list in the order indicated. The "earlies" were planted 5 inches, the "late" 7 inches deep, and, according to my usual practice, none were earthed up, except in two cases for the sake of experiment which has before been tried with a similar result. Twenty-four tubers of equal size and weight were taken of Bresee's King of the Earlies and also of Model, and were planted in one row; twelve of each were earthed up in the usual way, and the other twelve left without any earthing. The twelve earthed up roots of King of the Earlies yielded 13½ lbs.; the remaining twelve, not earthed up, yielded 13½ lbs.; there was, therefore, not much gain in earthing up with these. With Model the difference was greater; the twelve earthed up yielded 26 lbs., the twelve not earthed up 34 lbs. These two varieties were only chosen in preference to others because the seed in each case was so exactly level and very good. As regards whole and cut sets, I have tried many experiments, and I much prefer the whole; with some of the coarse and strong-growing sorts it makes little difference in the yield. Red-skinned Flour-ball in the foregoing table is a curious instance of this, but I believe in all cases the constitution of Potatoes grown from whole sets is stronger than of those from cut sets. Nos. 14, 15, 18, and 24 were new seed, the rest were new in 1873. The superiority of the crop from the new seed (except No. 15, which did not yield as it should have done) is very marked; the more so as the rest were new in 1873, and were grown in 1872 on totally different land in another county. No rule is without an exception—No. 22 was a better crop last year than in 1873. I have above alluded to the principal causes of the failure of the "earlies," and, I may add, not having unlimited room, I am obliged to grow some on a 10-foot border backed by a hedge, which always affects the yield; Nos. 1, 2, 3, 6, 7, 8, 9, 10, and 16 were so grown. W. N.

* Whole sets; † cut sets.

A NEW VEGETABLE.

THE Witloof is the name of a vegetable unknown in France, but which deserves to be used for the table in other countries, as much as it is in Belgium. This vegetable is the head formed by the radical leaves of a peculiar variety of Chicory which has been called the Large-rooted Brussels Chicory. It bears much resemblance to the Magdebourg kind, which, in fact, may be used in the same way; whilst the Brunswick sort is, on the other hand, totally unadapted for the purpose. In Paris, the Barbe de Capucin, which is wild Chicory blanched, is a very common salad plant. Its slender roots, which are seldom thicker than a lead-pencil, terminate in white leaves which attain a length of 7 or 8 inches, or more. In the Witloof, on the contrary, the root is thick and stubby, and carries a head of erect leaves that are stout, thick, and imbricated, forming a small compact head, which reminds one of the heart of a Cos Lettuce. In fact, except as regards whiteness, which is common to both when blanched, the Witloof is in all respects the very opposite of the Barbe de Capucin. The Witloof, unlike that kind, is brought to market deprived of its root, which is cut off a little below the leaves, as is done with the Dandelion. It is extremely tender, and has an agreeable, but slightly bitter flavour, which reminds one of that of Endive. The bitterness of the Barbe de Capucin is not agreeable to every one; but in the Witloof it is less apparent. In Brussels, the heads of the Witloof are cooked whole, and eaten with white or cream sauce; but it is equally good as a salad. It is all the more valuable on account of its being obtainable at a season when other vegetables are comparatively scarce, the markets of Brussels being supplied with it from Christmas till Easter, and later. The seeds of this variety are sown during the first fortnight of June, in good and rather deep garden soil. The only care to be taken is not to crowd the plants too much. The roots should be about 4 inches apart, in order that they may be thoroughly developed, for upon the size of the root the beauty of the head in a great measure depends. From the end of October to that of February a trench, from 3½ to 5 feet wide, and from 8 to 16 inches in depth, is opened in a favourable part of the garden. In the bottom of this trench, after having cut back the leaves to a length of about 2 inches, the roots are planted upright, or very slightly inclined, at a distance of an inch from one another, and in rows about 8 inches apart. Between the roots light soil or compost is placed so that no space may be left, and finally the surface is covered with about 3 or 4 inches of this light soil. The planting is then finished, and the development of the leaves now only depends upon the heat applied. The system of heating adopted in Belgium consists in putting a bed of fresh stable manure, of the thickness of from 2 to 3 feet, over the plants. This, perhaps, is a somewhat primitive and expensive method of forcing, as by it a large quantity of manure is required and much trouble involved; for example, it is necessary to cover the manure with planks to protect it from heavy rains, and it is quite possible that less costly methods of treatment might easily be discovered. However this may be, if the heat be sufficient the heads are fit for cutting a month or six weeks after it is applied, and will then measure from 3½ to 6½ inches in height by 1 to 2 inches in diameter. The heads are cut before the leaves reach the manure, in fact, when they are an inch or two from it, and this saves them from being embrowned and spoilt. The word Witloof means literally "White leaf."—"Journal de la Société Centrale d'Horticulture."

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Why Cucumbers are Bitter.—One of the causes which gardeners give for Cucumbers being bitter is slow growth. In order to secure sweetness and crispness, they say that they should be forced to grow as fast as possible.—B.

Forced Rhubarb in the Market.—It may not be generally known that large quantities of the early Rhubarb in our London markets come from Yorkshire. It is forced by the warmth of the waste water from the boilers of the factories in the neighbourhood of Leeds and Bradford, and has become a useful vegetable in January and February.—W. A.

Preserving Broccoli from Frost.—It is well known that Early Winter Broccoli often suffers severely from the effects of frost, and sometimes whole plantations become irremediably injured. One plan, says the "Florist," of preserving Broccoli is to pull them up by the roots as soon as they turn in ready for use, and to suspend them from the roof in an airy shed till wanted. By adopting this means they are preserved from injury from frost, or from rotting through exposure to heavy and continuous rains; and they remain fit for table use for eight or ten weeks.

Veitch's Dwarf-curbed Borecole or Kale.—After a long and somewhat severe winter, it is pleasant to say that this vegetable has been proved to be entirely frost-proof; and, although in ordinary winters when Broccoli and Cabbage are abundant, we are too apt to despise the more humble Kale, yet I doubt not that during the last few months the value of this excellent vegetable has made itself well-known to many. Its large leaves are quite equal, if not superior, to any kind of garnishing for large dishes in mid-winter. The crown is also an excellent dish, while the young sprouts in spring are equal, if not superior, to any green vegetable that is grown.—JAMES GROOM, Henham.

BURNING LIME IN A PIT.

LIME may be burned without a kiln by laying a foundation of blocks of stone, covered in such a manner as to make draft passages to the centre of a round heap of say 12 feet in diameter. The form of the foundation is shown in fig. 1, and the manner of making the draft-flue is shown in fig. 2. The draft-flues are filled with dry kindling-wood, a layer of coal-slack 3 inches thick spread over the foundation, and a layer of limestone 12 inches thick placed upon the slack; then a layer of slack, then limestone, and so on alternately, until a heap is made like that shown in fig. 2. This is covered with leaves, sods, or coarse manure and litter 12 inches thick, and then with earth for 6 or 8 inches. In the centre of the heap, as it is built up, a chimney about a foot in diameter is left, and this is filled with kindling wood and slack. When all is ready, the top of the chimney being left open, the fuel is kindled. When well on fire, the chimney is closed by throwing limestone in it until filled, and then covering it with leaves or litter and earth. The fire is made to burn gently by regulating the draft-holes, which should be closed with pieces of limestone covered with earth, and only one or two kept partially open to draw the fire to the side where it is wanted. In short, the fire should be managed exactly as that of a charcoal pit, except that a greater heat is needed. As the pit sinks down, earth and leaves, or litter, should be thrown over the cracks, lest the fire become too strong. In about a week the lime will be burned, when the draft-holes may be closed and the heap left to cool. Then the earth is

Fig. 1. Foundation of Heap.

Fig. 2. Heap ready for burning, and plan of draft-flue.

raked off, and the partly-burned stone from the outside laid on one side for another pit, and the lime may be removed. By this method (says the "New York Tribune") forty loads of lime (1,000 bushels) may be burned with six loads of coal-slack and one cord of wood. The lime thus obtained should not cost over 5 or 6 cents a bushel.

VOX NATURÆ.

Low heard the river reeds among
The wind responds with whisper'd sigh,
To that sweet chant by wavelets sung,
As onward to the marge they hie.
Or, roaring thro' the forest blown
Till branch with branch is interlock'd,
The north makes all the woodland moan
In rude embrace unceasing rock'd.
Who would not own the magic spell
To probe the purport of the breeze,
To glean what zephyrs soft would tell
When gone a-wooing 'mong the trees?
What means the fond confession made
By airy sighs in even's ear,
What message breathes from shade to shade
In ev'ry rustle that we hear?
Doth Brake to Briar its tidings send,
Doth leaf with leaf a converse hold,
When breezes thro' the upland wend
And die again along the wold?
Mayhap we view an angry strife
'Twixt Oak and Ash, 'twixt Beech and Elm,
And envy mars the sylvan life
When storms, we think, the woods o'erwhelm.
Such fancies stir the dreaming mood
Of worshippers at Nature's shrine,
And add a charm to solitude,
Amid her mysteries divine;
When clearer to the sense reveal'd
Comes all her varied utterance,
And what to dullard ears is sealed
Makes eloquent the poet's trance.
Be ours the hearing thrice refined
The eye with inner sight endow'd
To catch the voices of the wind,
And shape the changes of the cloud.

—"All the Year Round."

GARDENING FOR THE WEEK.

Indoor Fruit Department.

Vines.—Young Vines must be treated very carefully about this time, as much of their future success depends on a good start. As soon as the growths of early cut-back plants are 3 feet long they may be shifted into 10 and 12-inch pots. These are very suitable, and quite large enough for all fruiting canes. Any which may have been plunged up to the time of potting should have no such treatment afterwards, as it is much better never to encourage the young roots with bottom-heat. Three inches of broken crocks must be placed in the bottom of each pot for drainage, and the round bits of turf may be laid with advantage over the surface, before putting in any fine soil. It is of much importance that the soil used for potting should consist of the best fibrous loam, and, as bone meal is the most nutritious matter which can be used as a manure, an 8-inch potful may be added to every barrowload of loam. In potting, the ball should be well let down into the pot, so that the base of the young shoot is covered when the soil is filled in to within half a finger's length of the rim of the pot. When this is done many new roots are emitted from the stem, which otherwise have no chance of existing. Where it is convenient the newly-potted plants may at once be set in the position they are to hold throughout the season, and much trouble in shifting large heavy pots will be avoided. The back wall of a Pine-stove, or a similar position where the sun's rays have free access, is the place where they are most certain of arriving at a perfect maturity. As soon as they are put in position, each ball must be moistened with water through a fine rose, and little more should be given until the plant shows signs of growing. The foliage should be sprinkled daily with the syringe, and the atmosphere may be kept humid, with a temperature of not less than 65°. Keep the surface soil in young Vine eye pots well stirred up, taking care, however, not to injure any of the rootlets which may happen to be quartered about the surface. Barbarossa, Syrian, and other free-growing kinds may be in advance of other sorts. As each produces a healthy shoot about 12 inches high it should be removed from the influence of bottom-heat.

Pines.—Where a constant succession of Pine fruit is kept up, Smooths and other sorts should be in readiness to come in after the Queens. This cannot be brought about in a few days or weeks, unless the plants have been in preparation throughout the winter, when little difficulty will be experienced in causing a few of them to show by a few degrees of more heat. Plants for late autumn fruiting may be kept growing in a temperature of 70° at night, with 10° more by day, before admitting air. Air may also be given to those plants potted recently, when the thermometer indicates the heat I have mentioned above. The ventilators should be closed early, so as to shut in as much sun-heat as possible; much fire-heat may be dispensed with if attention be paid to this. Do not keep the atmosphere about Queens saturated with moisture, or long unsightly crowns will be the result. A syringing overhead at shutting-up time, and the moisture derived from the evaporating troughs, are generally sufficient.—J. MUIR.

Hardy Fruit.

At length there are indications of the approach of spring, which will be all the more welcome after the past winter, which, if not very severe, has been an unusually long one; and it is satisfactory to find that hardy fruit trees have not suffered, but that there is promise of abundance of fruits of all kinds, and the season being so late is all in favour of the trees escaping injury to their young and tender foliage by cold north-east winds, generally so prevalent at the end of this month. Apricots are just opening their flowers, which this year are very fine, and tell plainly that the tropical heat of last summer suited them, where (as was the case with us) plenty of water could be given them. Peaches are later, but both should be covered up at night, and also during the day when the sun is powerful. Pears are also ready to burst their buds, and the first warm day will bring many kinds into full blossom. If requisite, these can be easily protected with tiffany thrown loosely over them. For cordons and espaliers this is the very best protection; but dwarf bushes or pyramids are best protected by shaking dry hay over the trees. The birds, especially bullfinches, have been very busy among the buds, and the gun has been brought into requisition again; for, after trying all other known remedies, this is found to be the only effectual one. The season for grafting having arrived this should be effected without loss of time; the best method is what is called cleft or wedge grafting—the name of which expresses the nature of the operation. If the grafts or scions were cut and healed in as previously advised, they will now be in good condition for use. After the insertion of the grafts there is nothing better for the exclusion of air than the old-fashioned plan of moulding clay with the hand, care being taken to have it thoroughly adhesive, so that it may not be washed off with the rain. Newly planted trees will be likely to suffer from the

drying winds so general at this season, as a remedy against which I repeat my advice to mulch. There is nothing that more effectually saves vegetable life; watering is not to be compared to it; indeed, it is seldom required if mulching be attended to so soon as the trees are planted. Strawberry beds should have ordinary stable litter applied to them at once; its manurial properties will then be washed into the ground and prove of great assistance to the crop, whilst the straw will remain to keep the fruit clean, and is much better and neater than new straw put on at the time of ripening.—W. WILD-SMITH, *Heckfield*.

Flower Garden and Pleasure Grounds.

It is not, perhaps, possible to produce, by means of spring-flowering plants alone, that simultaneous and continuous display of richly-coloured flowers and ornamental foliage which it is easy enough to accomplish in the case of summer-bedding plants at a more advanced period of the year. But, nevertheless, from the present time until about the last week in May, or later, did circumstances permit, a display of considerable beauty and of great interest may be furnished by the use of spring-flowering plants and early bulbs of various sorts. About the time mentioned, viz., the end of May, such plants must necessarily be removed to the reserve garden or elsewhere, to set the beds at liberty for summer-bedding plants; and the present season has been by no means conducive to an early production of flowers. But with improvement in the state of the weather, development in their case may now be expected to be sudden; and, with a view to add as much as possible to their attractiveness, let every part of the garden be kept in the best possible order. Lawns and walks should be frequently swept, in order to remove fallen leaves, worm-casts, &c. Worms are sometimes exceedingly troublesome about this time, and to destroy them, or, at least, to drive them away, use clear lime-water, put on through the rose of a watering-pot. Mowing will soon be required; in some localities, indeed, this is already the case, and it should not be long delayed, as the production of a fine green sward is of the greatest importance, adding, as it does, very materially to the beauty and attraction of the garden. In many garden establishments there is a somewhat interesting appendage, which is known as the hardy Fernery, the rock garden, or the rootery, and which is generally to be found in a somewhat shady and secluded situation. It is usually devoted to the culture of the more hardy kinds of Alpine plants and Ferns; and the wild or wilderness-like character of this department, being so distinct from the monotonous formality of the modern flower garden, is much appreciated by some, as affording a pleasing relief to the dazzling effect produced by the bright colours of what are termed bedding plants. The rock garden may of course contain, in addition to Alpine and other hardy herbaceous plants and hardy Ferns, many dwarf hardy shrubs, such as the *Deutzia gracilis*, *Skimmia japonica*, &c., and such plants as the *Bambusa Fortunei*, and *Yuccas* of various kinds. All such gardens should now receive attention in the way of forking-up and enriching the soil, removing everything in the shape of weeds and litter, and adding fresh soil or compost wherever it may be found necessary. It is always advisable to allow hardy Ferns to have the natural protection of their decaying fronds during the winter months; but these should all be cleared off now, and the surface soil should be refreshed, weeds eradicated, and deficiencies (if any) made good by plants turned out of pots which may have been wintered in pits or frames. In most localities, many interesting varieties of native Ferns may be collected at the present season from woods and hedge-rows, &c., which may, if required, be introduced to this department. The cold drying winds, which we have recently experienced, are very injurious to recently transplanted trees and shrubs, more especially to large-sized evergreens, all of which should have a liberal supply of water now, an application which should be followed by a mulching of manure, in order to prevent, to some extent, evaporation from the soil. It is of the utmost importance to care well for such plants after they have been transplanted until they can form fresh roots; for, if this is not done, the plants frequently get so much injured that a season's growth, at least, is lost, even if the plants should ultimately recover, which is not always the case.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

Among summer-flowering and climbing varieties may be included the Ayrshire, Boursault, Evergreen, and the Hybrid Bourbon and Chinese Roses, the floral display made by which lasts only about three weeks; but there are other kinds of summer Roses that are not perpetual flowerers, such as the Damask and Gallica classes; among these, such kinds as *Madame Hardy* are, however, well worth growing; it is pure white, and a well formed Rose. Nevertheless, *Boule de Neige*, among the Hybrid Perpetuals, is quite as good as any summer Rose; if, therefore, a good white Rose is required for a

conspicuous situation, I would recommend this Hybrid Perpetual; but if for a shrubbery, or for planting near trees, the summer flowering climbing Roses are best, as they are stronger growers than the Hybrid Perpetuals, and can be trained so as to have a fine appearance. These are the only classes of Roses that require more skill as regards pruning than the Hybrid Perpetuals, with which we may associate the Bourbons, Teas, and Chinas, as well as most of the Noisettes. The latter, indeed, may be termed perpetual flowering climbing Roses, most of them being useful as climbers, and also as pyramid and pole Roses; if pruned so as to leave the shoots long enough for training, these form excellent pyramid or trellis Roses; for, when the points are brought down they flower from every lateral shoot. This applies to *Maréchal Niel*, *Lamarque*, *Desprez*, and *Solfaterre*; but, besides these, there are other varieties of the Noisette class that are not useful for climbers, such as *Triomphe de Rennes* and *Narcisse*, which are more compact growers, and make fine standard or close growing Roses. The Boursault and Ayrshire Roses are all useful in rough situations, as they are free flowering and strong growers, and are quite hardy. In pruning these should be well thinned, leaving, however, enough to cover the pole or trellis. Close pruning they do not require. The Hybrid, China, and Bourbon Roses should be pruned differently; take, for instance, *Charles Lawson*, an excellent Rose for covering lattice work, and it also makes a good standard. Of this I have some two dozen standards, and it also makes a valuable pole Rose. *Miss Ingram* is also equally useful. Hybrid Bourbon *Coup de Hébé* is another excellent Rose; but we have a Hybrid Perpetual nearly equal to it, both in shape and colour, in *Auguste Mie*. Most of the Roses, Hybrid, China, and Bourbon varieties, make very good pole Roses, and many of them are also excellent climbers. Among rosy-blush climbing kinds, one of the best is *Blairii No. 2*; it is good in shape, and valuable for cutting from. *Madame Plantier*, a beautiful white cluster Rose, is also useful for furnishing cut bloom, and is an excellent climber. These may be all pruned in February; in no case do I hold with pruning out-door Roses in November. In very mild weather in December and January the buds start, and the shoots get quite crippled. Hybrid, China, and Bourbons are useful for planting in shrubberies as standards, or in the form of bushes, but I do not recommend many of them to be used as standards, as the Hybrid Perpetuals are better suited for that purpose.—H. S.

Kitchen Garden.

Asparagus.—Many people of limited means are deterred from cultivating Asparagus by erroneous impressions respecting the expense of the preparation of the beds. During the last two or three summers, I have been watching the development of a plant of Asparagus that came up accidentally in the shrubbery—where, as it is, on the whole, rather an ornamental plant, it was allowed to remain. It has never had a particle of manure; but the soil, although not particularly suitable, is of considerable depth, its level having been raised a good many years ago; and to this depth of soil, accompanied by space for development, I attribute its wonderful growth. Asparagus delights in abundant supplies of water; and, in deep, well-drained soils, this might be made to convey nearly all the manure necessary for its successful cultivation, with the exception of mulchings, and occasional sprinklings of salt. I believe there is no occasion to raise the beds into such mounds as are commonly made. A moisture-loving plant, like Asparagus, would do better (except on cold, clay soil), if planted in trenches rather than on mounds, and this system of trench-planting is especially adapted for poor, light, sandy soils, as it offers such facilities for easily flooding the plants with water. In making new plantations, whether the old bed system, with its elaborate preparation (and I have no desire to find particular fault with it) be adopted or not healthy plants from one to two years old are the best for planting; and the most suitable time is just after growth has commenced, usually in April. Where many roots are required for forcing, I should certainly recommend it to be grown in single rows, not less than two feet apart from each other, and at least 1 foot apart in the rows. The way to secure fine produce is to encourage individual growth by allowing each plant plenty of space for development; this is more profitable than thick planting, where a continual struggle for existence must be going on. It is best to raise a bed of seedlings every year sufficient to make a new plantation to take the place of that removed for forcing, or rather to come on in succession. In planting, make a drill or trench wide enough to receive the roots without cramping them, cover with 2 inches of fine light soil, and water abundantly in dry weather, giving sewage or liquid manure whenever possible. When taking up the roots allow as little exposure to the air as possible, to avoid giving too much check. Early Cauliflowers under hand-lights should be earthed up, and watered with liquid manure, and have as much air as can be given

without unduly checking growth; a brick might be put under the edge of the glasses on the south side, and the top ventilators moved a little; but the weather here still continues severe, although probably we are not far from a change. All forced vegetables, such as Potatoes, Carrots, Turnips, Lettuce, and all kinds of salading, must have sufficient tepid water given to keep the soil in a healthy state, as regards moisture; an exception should, however, be made in the case of Potatoes that have completed their growth. From a pound to a pound and a half of guano to 36 gallons of water makes a cleanly and very serviceable mixture, suitable for most plants in robust health, but such strong stimulants are often worse than wasted upon weak spindly plants, from the latter not having the power to take up and assimilate what is given to them. If there is a demand for Parsley roots at any time in the kitchen, a row or two of the *Hamburgh Parsley* should be sown now, and be well thinned out when large enough. *Borage* is often required in some establishments, and should be sown at once. There is one peculiarity about this plant; if it once goes to seed in a place, it will keep coming up for several years; I have not sown any for years, and we always have plenty. It is rather a pretty plant for back shrubbery borders, and bees are very fond of it; as this is at present a backward season, a few plants might be pushed on in heat. *Balm* and *Sweet Verbena* are usually used in conjunction with it for flavouring claret-cup; they also should be forwarded in heat, as required. Renew or increase plantations of *Sorrel*, by dividing the roots and planting them in rows a foot apart each way. *Fennel* may be sown now, and thinned out or transplanted when large enough. To ensure a supply of green *Mint* at all seasons, it is best to make new plantations frequently; for example, at the present time, plant a bed under a north wall, another patch in the same position towards mid-summer, and again later on towards the end of the summer, in a warm sheltered spot. If the latter does not yield a picking in the winter, it will very early in the spring, and save much forcing. If the long creeping roots are cut into short pieces, and planted in rows with a trowel or dibble, the thing is soon done.—E. HOBDAI, *Ramsey Abbey*.

SUNKEN BOILERS.

If there be one subject on which I should have expected all gardeners to be agreed it would have been that of the advantage of a good rise from the boiler to the pipes, for a young gardener soon becomes acquainted with the stokehole, and the impressions then formed are often not readily effaced. He must make a poor use of his time, if he does not come to a conclusion as to what form of boiler and arrangement of pipes carry the heat most speedily and effectually to its destination. My own experience fully bears out the remark of your correspondent, Mr. R. S. Dunbar, that, unless there is a good rise from the boiler, there must be a great waste of fuel in forcing the water along dead-levels, and that however much boilers or pipes may be altered and improved, the laws regulating the circulation of water will remain the same—the hottest water will still flow upward, as naturally as smoke from the furnace, and although it may be forced to take an opposite direction, it is contrary to reason to suppose that it will circulate as speedily or effectually as if it were allowed to travel uninterruptedly. A boiler must be able to do its work easily, if it is to do it well. With regard to the form of boiler, I am of opinion that the tubular, or a combination of the tubular and saddle, is as good a form as can be desired; but so much depends on the setting, arrangement of pipes, and, perhaps above everything, upon the stoking, that it would be hard to decide between the rival claims to superiority; nor does it affect the present question. Nearly every form of boiler that I have yet met with is good, if intelligently used; but many are so fixed that they work under difficulties; and, consequently, they do not give the satisfaction they ought. If it were left to the gardener, who is to be held responsible for the working of it, and to the hot-water engineer and his assistants, who are to fix it, the right boiler would generally be put in the right place; but too often others, with more influence, but less knowledge of what is required, are consulted, and such alterations are made as ruin the whole affair. I believe that amateurs are the greatest sufferers from purchasing boilers that are advertised to do more work than they are able—the most expensive of all kinds of economy, and one that generally ends in the remodelling of the entire apparatus being rendered necessary. I am confident that it is more economical, as regards fuel, to have rather too much than too little of boiler power and pipe surface. I do not see the slightest reason why it should be more difficult to keep water out of stokeholes than to retain it in cemented tanks, which may be seen in all gardens of any size; but I can see the most weighty reasons why a position where such precautions are necessary, should be avoided altogether for forcing houses for Vines, Peaches, &c., which must be planted in borders (usually below the level of the pipes), and which, as they are in full growth in early spring when the

water would be highest, would be more likely to suffer at the root from moisture than the stokehole. Any good bricklayer could keep the water out, as one coat of cement ought to last as long as the boiler, and in the worst cases, even for tanks for heating water almost to the boiling point, a easing of flat tiles, in addition to the cement, will make it hold or keep out water as well as an iron tank.

Henham Gardens.

JAMES GROOM.

I have just completed a new *Vinery*, and having to contend with the difficulty of which some of your correspondents complain, I placed the heating in the hands of a hot-water engineer at *Macclesfield*, who at once relieved me by putting in one of his boilers, which require no sinking. The level of the flow is some three feet below the crown of the boiler (a vertical tubular one), and its action, which has been all that could be desired, has been fully proved during the late severe weather. Having had the boiler and pipes filled (to prove the joints) before the roof was glazed, and having no means of carrying the water away if I had run it off on the setting in of the frost, I was compelled to begin firing, and, though in the open air, the pipes were kept quite hot during the whole time the frost lasted, and stoking was only required at intervals of twelve hours or thereabouts.

HUGH FORD.

43, *Park Green, Macclesfield.*

I was pleased to see Mr. Dunbar's practical reply to Messrs. Williams and Hobday on this subject, and must say that my experience fully coincides with his. While I admit that it is possible for an apparatus like Mr. Williams's to work, provided it has the pipes at about the same level from the foot of the upright syphon pipes till the return enters the boiler, the necessity for the large expansion pipe clearly shows that a great deal of extra power is required to make the water circulate in the apparatus, as the cold water in the level return pipe will not run in the boiler until it is forced by the pressure of the almost boiling water from above. On the other hand, in an ordinary apparatus, with the boiler sunk below its work, the water, the moment it becomes the least warm, circulates at once, because the cold water in the return, being heavier, falls naturally down into the boiler. In the early days of hot-water heating, an engineer invented a valve which made the water circulate through dips in the flow pipes; it worked on the same principles as a hydraulic ram, that is, the water was heated up in the boiler till the pressure became strong enough, when it burst through the valve. The valve then shut again, and retained what it had got, until the cold water, which took the place of what went through the valve, became heated, and the operation was repeated. This was very ingenious in its way, but the principle on which it worked was nearer akin to steam power than that of hot-water circulation; and it appears to me that it is on this same pressure system that Messrs. Williams's and Hobday's apparatus works—without a valve, of course, but still by the pressure. That the same apparatus, with sufficient provision for expansion, would work, even without the upright syphon, was proved by the apparatus shown by Mr. Cowan, at Manchester, in 1873, where the power expended would have been greatly in excess of what was necessary, had the boiler been below its work. About a year ago, I tried an experiment with a powerful boiler, having about 40 feet of 4-inch pipe attached to it, with a dip about 20 feet from the boiler; just before the dip T connections were put on, and a 9-foot flow carried out at right angles to the main pipes, and returned with a syphon into the main return pipe; yet, though the boiler was fired hard for two days, the water would not go down the dip, but circulated very fast through the side pipes, clearly showing that, even with great pressure, water will not go past a dip, if it can circulate without doing so. It is, I think, rather hasty to jump to the conclusion that it is needless to sink a boiler below its work because of Mr. Williams's apparatus acting without being sunk; for I am afraid it would not act in any case where more than one house was connected to the main supply pipes, as the surface pipes would be on a higher level. As regards Mr. Hobday's apparatus (see page 252), it is quite possible for it to work as described if the pipes are arranged in a particular way, especially if the boiler is an upright one, as in that case, though the flow goes down 18 inches or so, on leaving the boiler, it may still be considerably above the point at which the return enters it, and with the assistance of the 3-inch expansion pipe, in which the perpendicular pressure will be pretty strong, it may work well enough with a powerful boiler. With reference to the dips in the pipes, of which Mr. Hobday speaks, there are certain conditions in the absence of which no hot-water apparatus will work, but if these conditions are attended to (no matter in what way), the apparatus will work; this being the case, it is quite impossible for anyone to give a decided opinion regarding any apparatus without first seeing it. The fact still remains, however, that it is much

better, and in most cases necessary, that a boiler should be below its work. As I expect to be in Ramsey shortly, I will, with Mr. Hobday's kind permission, take the opportunity of seeing the apparatus, and should I find that I am wrong with regard to any of the statements I have made, I shall be only too glad to acknowledge my error, being anxious to hear of anything new and meritorious in hot-water heating. In conclusion, I may say that most hot-water heating engineers are just as anxious to find out any improvement upon the present system as anyone else can be, and, generally speaking, have much greater opportunities of doing so by means of experiments. Heating by hot water is a rather intricate affair, and can only be thoroughly understood after long and careful practical study; so that anyone trying to get an apparatus to work without sinking the boiler need not be astonished to find that it will not act, owing to some slight difference from Mr. Williams's apparatus which one would not expect to alter the result.

AQUA-CALIDA.

Mr. H. Ormson has lately called at our office with drawings and models of a boiler which will shortly be made public, and the special feature of which is, that it can be placed in position without any stoke-hole whatever.

Mole Catching.—Never trap for moles where they work, but select the side of a footpath or gateway, where they have shallow runs. Rub your trap well with a dead mole, and use the old wooden trap with a spitter or bent spring. If the mole works by the trap, open his road a foot each way, rubbing the same with a dead one; peg or pile the run on each side with small sticks, and lay a turf gently over them, keeping out the light, a plan which I have never found to fail. Moles run chiefly in March. I have frequently watched the trap-spring, and have taken seven and eight out of one run. Moles, although troublesome in gardens, ought not to be extirpated in fields or pastures; they live upon the larvæ and pupæ of insects, especially wireworms, which fall into their burrows, and also field mice.—H. R. H.

The Colorado Beetle.—The Colorado Beetle, Dr. George Lawson, a learned professor, of Halifax, Nova Scotia, asserts is not likely to live, or at least to thrive in our climate. We have already indicated as much ourselves, but the professor tells us that the much-dreaded pest is quite unknown among the Bluenoses, the summer climate of the colony being so moist and cool that several other insects, that are troublesome in inland regions on the same parallel, are unknown there; and for a similar reason, although suitable conditions for the propagation of the *Doryphora* may be found in central Europe, it is not likely to establish itself permanently in the British Isles. A hot and dry Continental climate seems to be necessary for its development, its possibility of existence depending upon the degree and continuance of summer heat. Indeed, from his own knowledge, the professor asserts that for the last two or three years numbers of Colorado beetles have been sent to England in produce from all parts of the American Continent, it being absolutely impossible, he says, to pack up any kind of produce without their getting into it; and if even a few of these had survived, one or more of our lynx-eyed bug-hunters would have been shouting pæans over the discovery of a rare species in some entomological magazine or meeting.—“Iron.”

The Enclosure Commission Report.—The report for 1874 states that the acreage of enclosures confirmed since the passing of the Act is 587,867 acres, and the estimated acreage of enclosures in progress is 83,868. Of the 587,867 acres in confirmed enclosures, the number from which public allotments would be required by the commissioners is 414,046, and the extent set out as public allotment for exercise and recreation, and for gardens for the labouring poor, is as follows, viz.:—For exercise and recreation, 1,746 acres; for the labouring poor, 2,183. The commissioners state that they have felt it their duty to discourage fresh applications for enclosure pending the decision of Parliament on the conditions upon which sanction shall in future be given to further enclosures of waste land. The return, printed by order of the House of Commons last year, affords (they add) the most trustworthy data we have yet possessed regarding the extent of common lands still unenclosed. It is there shown to be about one-fourteenth of the entire surface of England and Wales, being 2,632,772 acres in extent. Two-thirds of this are in the mountainous and more elevated districts of the country, and one-third in the lower counties. Adding the apparently cultivable and “common field” lands together, there would seem to be more than one million acres still available for improvement, and for extending the productive area of the country. And much of the high land, though unsuitable for cultivation, might be greatly improved for pasturage or plantations, if released from common rights and held in severality.

NOTES AND QUESTIONS—VARIOUS.

Mice Destroying Christmas Roses.—Every flower-bud was eaten off each plant of Christmas Roses in my garden last winter by mice, and thus an important source of cheerfulness during the winter season was destroyed. I never knew this happen before. Can anyone suggest a protection, failing the evident one of killing all the mice.—SALMONICRIPS.

Eupatorium ageratoides.—This will before long become a general favourite with all who force flowers for the ornamentation of the conservatory in spring, and for cutting for house decoration, for few plants are more easy to grow and flower. Its beautiful white blooms are profusely produced, and, being on moderately long foot-stalks, they are of additional value for bouquets and for the decoration of vases. A large plant of it when well trained is a splendid sight.—N. H. P.

Elæagnus japonica variegata.—This, and its variety *aurea marginata*, has proved perfectly hardy here this winter, withstanding the severity of the weather without the slightest injury. Taking into consideration their free habits of growth and distinctly variegated foliage, these are likely to prove valuable for relieving the general monotony and sombre appearance of our shrubberies. They are amongst the most ornamental shrubs of recent introduction.—GEO. WESTLAND, *Witley Court*.

The Dwarf Daffodil.—I saw this small early-blooming *Narcissus* a day or two since in an old cottage garden in the village of Heckfield, and not having seen it before it was an agreeable surprise. The flowers are pale yellow, trumpet-shaped, and single, growing to a height of 6 inches in a thick cluster, foliage proportionately small. It is evidently the earliest to flower of all the family, and is charming for pots in the hardy plant house. As seen by me, with clumps of *Scilla siberica* and *bifolia*, it was very beautiful.—A. D.

Hardiness of different Laurels.—Mr. Hutchison, of Carlrowie, speaking of the effects of the past winter, says it is a noticeable fact that the Caucasian variety of the Cherry Laurel has proved much harder than the common kind, while the Colchic variety, with its handsome narrow-shaped leaves, of paler green, have suffered most of all. The common Portugal Laurel (*Prunus lusitanica*) has been very much browned, and in many places is now shedding its leaves; and some of the young wood on the more exposed portions of the plant has been killed.

Cyclamens for Table Decoration.—It may be useful to many to learn that plants of *Cyclamen persicum* will bear being turned out of their pots, when in full bloom, and will last without flagging in a saucer or soup-plate for a week at least, provided their roots are kept damp. I lately arranged four groups of these plants in flat dishes on a long side-board, which had a tall back of looking-glass; from these floral bases sprang three slender brass-wire arches, which were lightly draped with climbing Fig (*Ficus repens*), from a hot-house, and the effect was very pleasing.—W. T. P.

The Venetian Sumach (*Rhus Cotinus*).—Few hardy deciduous shrubs are so ornamental and useful as this in August and September, either in the shrubbery or for cut flowers in dinner-table decorations. The flowers, which are red, shading to green on the under side, are more delicate than the finest ostrich feathers, and are very beautiful when spangled with the morning dew. I have used it most successfully in competition at exhibitions for table decorations; it also sells readily in Covent Garden. The plant only requires ordinary culture, but seems much less grown than it deserves to be.—JOHN GARLAND, *Killerton, Exeter*.

Dis-rooting Camellias.—May I ask Mr. Gadd if the plants he so fearlessly denuded of roots, many of which were as thick as one's arm, were previously cut down, or in what proportion the top was to the roots when so treated? I have had an extensive practice with Camellias in various forms, and have frequently cut down old plants which were planted out, allowing them to break previously to lifting and shortening back the roots. By this method they have invariably done well; but to suppose that plants with such roots as have been mentioned, without previous preparation, should be so treated, seems to me absurd. I also look upon good feeding, under such circumstances, as decidedly inimical to root formation.—IGNORAMUS.

Primroses for the Greenhouse.—The following Primroses are excellent for conservatory decoration:—*P. denticulata*, one of the earliest; *P. purpurea*, *P. marginata*, *P. erosa* (Fortunei), *P. nivalis*, and *P. helvetica*, all very attractive. *P. verticillata*, sweet scented, and a capital species. *P. japonica* is better than any of its varieties; it stands forcing well if kept close to the glass and in a temperature of about 55°. The same remark applies to *P. cortusoides* and *P. c. amœna*, which is also better than most of its varieties. There is a white variety of the old *cortusoides* sold for the true *amœna alba*, which I have found somewhat difficult to procure true. The double varieties of *P. acaulis* are worth growing in pots; *P. a. auriculiflora* is a very fine pot sort.—R. P. B.

Peach Setting Indoors.—I send you a few branches which will show you the thick way in which the fruit in my early Peach-house has set. About the middle of January, when the trees came into full flower, with the exception of watering the borders when the soft-water cisterns got full, and during the sunless days of January and February, general damping of the pathways was discontinued until I could perceive that the fruit was well set. I made no attempt at artificial setting, but on three occasions, and upon three of the brightest days at the end of January and beginning of February, I had the house and trees thoroughly syringed—twice in January about eleven o'clock in the forenoon, and the last time in February at one o'clock in the afternoon. This has been my practice for setting Peaches for several years. Out of this house I gathered 1,000 Peaches, besides Nectarines, last season.—J. MILLER, *Clumber*. [The branches of both Peaches and Nectarines sent were in excellent condition, and loaded with fruit.]

Cut Sprays of *Centradenia rosea*.—A failing of *Centradenia rosea* is the way in which it casts its blossoms when brought into the house, and even when in the stove. It is also impatient of the dry atmosphere of a room, where it flags. It has, however, one very valuable quality, viz., when cut, it stands for weeks in water, and for that purpose, and for winter when colour is scarce, it is very effective. Of a large plant, which to tell the truth was infested with bug and condemned to be burnt, I, for experiment, cut off the clean branches, and filled a glass with them, and for a trailer used pieces of the bright green *Testudinaria elephantipes*, or Elephant's foot. Both plants stood six weeks (December and January), and for three of these in a room without a fire during the extremely cold weather we had then. Not a leaf was shed, which surprised me exceedingly; and we are now striking a good stock to cut from next winter. *C. floribunda* and *C. grandiflora* are both worth growing, the one for its peculiar stem, and the way in which the leaves are attached; and the other for its broader leaves and larger blossoms; but *C. rosea* shows the dark red underside of its leaves (a great point for winter glasses) better than these two last-named kinds.—F. J. HOPK, *Wardie Lodge*.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE MOUNTAIN HAREBELLS.

WERE there no Alpine flowers but these, the hills and high rocks would yet be adorned with great loveliness of colour and airy grace of form. The woods, meadows, copses, and high treeless pastures of northern lands are everywhere gay with the Blue Bells of the larger species. Long after the blossoms of these are waving among the long early summer Grass, the higher Alpine kinds rest under the snow, impatient to unfold every tiny shoot that forms their tufted carpet, having the small dark bells folded up in its heart. Then when the snow dissolves from the worn stem and long-buried verdure, every shoot quickly unfolds its treasure, and every tuft bears a thousand bells or stars. The earth, recently sad in its snowy pallor, is now robed with varied blue—near us, around our feet everywhere, yet pure, and soft, and perfect as the hue of the deep sky overhead. And not only on sweet wide Alpine pastures, or in sunny hill copses, or sheltered hedgerows, or high snow-clad ranges, or lowland well-watered meadows is their soft beauty seen; in all these there is abundant plant-food and water; but it is the office of the mountain Harebells, also, to embellish the arid sun-burnt slopes of wasted earthless rock that sometimes form such vast walls about the southern feet of the great mountain ranges. Here, from crevices in the hard rock, from which the roots cannot be extricated, small Harebells spread forth graceful mantles of green, which in spring become as gaily jewelled with flowers as the kinds that live richly on the deep moraine gravel or soft mountain meadow-loam. The smaller Harebells creep down to the hot shores of the Mediterranean to stain with blue the hard rocks washed by its wave; and not content with the precipice, Alpine lawn, or other natural surface, these hardy children of the rocks invade the domain of man. In a two days' journey up one of the most varied, and, as regards its flora, the most interesting of the valleys of the Maritime Alps the writer and Mr. M. Moggridge saw nothing more beautiful than the curtains and tufts and seams of blue-purple of a Harebell, which had taken possession of the dry and by no means old walls of a bridge and its approaches. In the pleasant gardens of Western Europe, nothing is easier than to enjoy the loveliness of these flowers, and by the exercise of a little judgment they may be made to look almost as charming as in their wild state. The taller and medium-sized kinds are happy and long-lived in our garden borders, where, however staked and stiff, they are not very attractive when the full glory of bloom is past. A good many of these kinds may be naturalised in half-wild spots in woods and pleasure-grounds and by shaded Grass walks; in such positions the effect is very beautiful when the pyramidal fountains of blue Harebells appear above the long Grass and other herbs in such positions. I shall long remember the surpassing loveliness of a large tuft of Rampion, accidentally naturalised among wild Ferns and Briars, beside a Grass walk in Professor Owen's garden at Sheen, and which, wholly uncared for, of course, annually sent up showers of the loveliest Blue Bells, and formed by itself a little picture equal to anything elaborated with care and expense in gardens. The smaller kinds may also be frequently naturalised with ease. Old walls are welcome dwelling places for the species that abound on dry rocks in a wild state; wherever underlying rock crops up naturally a number of beautiful species may be naturalised. Our common English Harebell, and other nearly allied kinds, thrive and flower freely, though in a very dwarf state, among Grass that is frequently mown. In the rock garden all the mountain Harebells are easy of culture, and such few of them as may perish on the level ground in heavy soils endure long in dry crevices of rock; some of them like *C. fragilis* and *C. garganica*, have, when planted on dry vertical faces of rock, a habit of growing equally in all directions, pressing their star-laden shoots firmly against the inequalities of the rocks, and frequently flowering and extending themselves thus for months, the shoots (which do not cling or creep) never showing a tendency

to fall wearied from the rocks. Erect flowering kinds, whose shoots do not spread freely in this manner, like the beautiful *C. Pulla* and *C. Raineri*, are best on the more level spots, or on ledges of loamy soil, where they may spread into wide cushions. A number of interesting dwarf kinds, like the Carpathian Harebell and its varieties, and *C. turbinata*, thrive in ordinary soil in borders, forming pretty edgings, or looking better still in tufts on the margins or borders of hardy flowers.

GRAFTING APPLE AND PEAR TREES.

THE season for grafting having arrived, such fruits as Pears and Apples, that have proved unsuitable for the particular district in which they were planted, or that are considered unsatisfactory varieties, may now be headed down, and re-grafted with more valuable kinds, or with those that are better adapted to the locality. Amateur cultivators of fruits must, on looking over the lists of varieties of Apples and Pears, be often at a loss which to select, and many have doubtless experienced feelings of disappointment to find, after the trees have arrived at a bearing state, that they turn out different from what they expected. Those who grow these for sale are sometimes accused of giving somewhat flattering descriptions of them; yet, if the soil, locality, and aspect in which they are grown, happen to suit them, the merits of the trees may prove not to have been exaggerated. The quality of most kinds of fruit varies greatly with the seasons, and the soil in which they are grown. This is especially the case with Pears. A Pear, that may be faultless when grown in light loam, will be hard, gritty, and comparatively worthless, when grown in stiff soil, although the aspect and other conditions may be the same. *Passe Colmar*, a Pear often condemned as gritty and valueless, is one of the best we have here, and more juicy and luscious than any other that ripens at the same season. This we grow on the Pear stock, in light soil, and on walls having a western aspect. It is somewhat disappointing, after years of patient waiting, to find that a variety which has been planted is unsuited to the locality, and useless as a dessert fruit. When this is the case, it is best to head back at once, and re-graft. This operation may be successfully performed on trees of almost any age or size, and it matters little whether the branches to be operated on are large or small. The only difference is in the manner in which the scion has to be inserted. For large branches, I prefer rind grafting, and if carefully performed the operation rarely fails. The branches should be sawn off in a sloping direction, so as to have the cut face on the underside, to prevent wet lodging on it and rotting the wood before the wound has healed over. The saw-cut should then be made perfectly smooth with a knife, or sharp broad chisel. For rind grafting the scions should be cut flat on one side, beginning about 3 inches from the end, and tapering off gradually, so that the point to be inserted under the bark of the old branches headed back is made very thin. The point of the knife should be drawn through the bark where it is intended to place the scion, so as to allow it to be lifted from the wood before pushing in the graft. This operation can be best performed by cutting a piece of hard wood just the shape of the graft to be inserted. By having this a trifle larger than the scion, and thrusting it under the bark, the graft can be pushed in tightly without any fear of injury. Having inserted a sufficient number of grafts, they should be carefully tied in with soft string or bast matting, and covered with a preparation of clay and cow-dung, a composition which should be mixed in the proportion of two-thirds of the former to one of the latter. Old Pears or Apples operated on in this way soon regain their former size; and many that appear to be growing unsatisfactorily, often become healthy vigorous trees after they have been thus treated. Those of your readers who have inferior kinds of Pears, or more than they require of any of the many autumnal varieties that ripen in quick succession, will do well to head back, and graft with *Joséphine de Malines* and *Bergamotte Esperen*, two of the very best Pears which ripen from February to May, and to which *Ne Plus Meuris*, *Easter Beurré*, and others, that used to be depended on for affording a supply after Christmas, must now give place.

J. SHEPPARD.

NOTES OF THE WEEK.

— THE present spring is considered to be the latest ever known to cultivators in the London district. Fruit trees are very backward, and even the common Sloe, on the 27th of March, had not a trace of bloom on it.

— WE have recently observed on sale in London, the Ochra, a vegetable very popular in many hot countries. The succulent parts of the vegetable are dried; but, when soaked in water, or used in soup, swell and become as good as when fresh gathered.

— FIVE thousand one hundred and fifty-seven persons paid for admission to the Royal Horticultural Society's gardens at South Kensington on Easter Monday, the total amount received at the gates being £42 19s. 6d.

— PECCAN NUTS have recently become more frequent in our fruit shops, and we may take the opportunity of pointing out to lovers of Nuts the claims of this, one of the most delicate, and in every way desirable, of all. The Peccan is much liked in America, where it grows wild in many parts. It is the fruit of *Carya olivæformis*, and may be described as a small well-flavoured Walnut, shaped like an Olive, and with a thin fragile shell.

— AT the Regent's Park Exhibition, held on Wednesday last, a plant of *Anthurium Scherzerianum* was exhibited by Mr. Ward, gardener to F. J. Wilkins, Esq., of Leyton, bearing four enormous spathes, the largest of which measured 5 inches in length, and about 4 inches in breadth. It was not so brilliant in colour as an extremely narrow-spathed variety exhibited by Mr. Williams, of Holloway; but, as regards vigour and size, we have hitherto seen nothing equal to it.

— WELL-GROWN plants of the deep rosy-flowered *Spiræa palmata*, one of the most effective of all the species, and a fit companion for the white-flowered *S. japonica*, have made their appearance in Covent Garden Market during the past week. Last year a splendid specimen of this Meadow-sweet was exhibited at one of the Regent's Park exhibitions, measuring fully 5 feet in height, and 4 feet in diameter, and bearing at least fifty great rosy trusses of bloom.

— MR. H. C. HART, one of the naturalists appointed to the Arctic Expedition, has published a list of the plants found in the Islands of Arran, Galway Bay. From the geographical position and geological construction of these islands, their flora offers some interest. The total number of species hitherto observed on this group is 372, about thirty of which the author claims to have added to those previously known. The luxuriance of the Maiden-hair and other Ferns abounding in the deep fissures of the rocks, and the diminutive forms of many flowering plants on the thin crust of soil covering the rocks in some places, are characteristic features of the flora.

— THE April number of "The Florist" contains coloured plates of Tea Rose Catherine Mermet, and a new Pear named Lucy Grieve. The Rose is undoubtedly one of the finest in its class, and in form reminds one of Gloire de Dijon. The colour is delicate rosy-flesh, with a dash of salmon or buff-yellow in the centre of the flower. It is said to grow best on the Briar stock. Lucy Grieve Pear is above the medium size, and resembles Williams's Bon Chrétien in flavour. The fruit is golden-yellow in colour, shaded and speckled with reddish-russet. It received a first-class certificate at the Royal Horticultural Society's meeting, held on October 23, 1874, at which time we tasted it; it is a Pear of first-rate excellence, ripening in October.

— FROM the recently-issued Report of the Algerian Commission we learn:—"The Banana has made rapid strides, and is now an article of common consumption in that colony; but its cultivation, as yet confined to the environs of the town, might be extended so as to find a market in France, England, and Germany. Dried fruits, such as Almonds, Raisins, and Dates, are also adapted to the climate, and would find a ready sale in France, England, and Austria. Beans and Peas are largely exported, particularly to England. The Arabs have eagerly devoted themselves to their cultivation. The Alfa, which covers the interior plateaux—the sole vegetation of the Sahara—which is to be found also in the south of Spain and Portugal, has always been used in the East for hats, plates, mats, &c., and the Spaniards are very expert in using it for baskets, carpets, &c., while it may also be employed for the seats and backs of chairs. It is likely to be largely used in the manufacture of paper, for, mixed with rags, it gives increased consistency, and mixed with the paste manufactured from wood it corrects its brittleness. It has been successfully tried in England for the latter purpose, and the example has been followed elsewhere. Several English papers are printed on Alfa paper, but it will be necessary to take precautions against the Alfa being exhausted, as has to a great extent happened in Spain. They mention that the Algerian Cork tree is used for saddles, walls of houses, and penholders. Their lightness for this last purpose lessens

the fatigue of writing, and though only introduced into England a year ago, they are beginning to be appreciated here as well as in France.

— THE Bournemouth Winter Garden Company have arranged with contractors for the commencement of their winter garden, which is to be completed within twelve months.

— MR. JOHN DILWYN LLEWELLYN, of Penllergare, has given £1,000 for the purpose of laying out the people's new park at Knapllwyd, which he presented to the town of Swansea about three months ago.

— WE are requested to state, in reference to the Cologne International Horticultural Exhibition, that the ground allotted for planting shrubs for this exhibition is now at the disposal of intending exhibitors, who can at once commence to make use of it. No charge will be made for space.

— THE group of pot Roses, shown in splendid condition, by Mr. George Paul, at the Royal Botanic Gardens, Regent's Park, on last Wednesday, proved—if any proof were wanted—that the Rose may be grown to as great perfection under glass in early spring, as out of doors in the fairest climate in summer.

— IT is stated that it is in contemplation to ask Mr. Ellis Lever, the purchaser of Manley Hall, near Manchester, to consent to the conversion of the house, with the conservatories and grounds, into a winter garden for that city. The idea is to form a limited liability company to carry out the scheme. Manley Hall and grounds comprise an area of 80 acres.

— BLOOMS of the beautiful yellow Tea Rose, Madame Trifle, have been sent to us by Mr. Brush, gardener to Lady Hume Campbell, who states that it is one of the best of the Gloire de Dijon class, and superior to Belle Lyonnaise, being much thicker and firmer in the petals. It is not quite so vigorous as Gloire de Dijon. When forced, it is a rich yellow, as bright as that of Maréchal Niel.

— DEPÔTS are now opened at the Home of Industry, Commercial Street, Spitalfields, and Conference Hall, Mildmay Park, for the supply of the hospitals and missions nearest them. Flowers and fruits of all kinds would be most thankfully welcomed if sent addressed to the Secretary of the Flower Mission, at either of the above depôts, before 11 a.m. on Tuesday and Thursday mornings throughout the season.

— THE April number of the "Botanical Magazine" contains coloured plates of the following new plants:—*Phyllocactus biformis*, a slender-growing Cactus of excellent habit, from Honduras, bearing conspicuous rosy-carmine bell-shaped or tubular flowers; *Pentstemon antirrhinoides*, a shrubby yellow-flowered species from California; *Pyrus prunifolia*, with large white or rosy-tinted Apple-like blossoms and golden-yellow crimson-shaded or rosy-tinted Crab-like fruit; *Masdevallia Peristeria*, a yellow crimson-dotted Orchid from New Granada, closely resembling the green-flowered *M. civilis*, and having the same carrion-like odour; *Fourcroya undulata*, a green-flowered slender-growing plant closely resembling the common *F. Selloa*; *Cyrtoperia sanguinea*, a brown-flowered terrestrial Orchid from the Sikkim Himalayas, having a yellowish-white lip margined with rose, and a dark greenish spur.

— MR. F. L. OLMSTEAD (the designer of the Central Park), writing to us from New York, under date 6th March, says:—"We are still in the middle of winter here, the snow nearly a foot in depth, and our spring will probably be very late." The "Signal Service Review" for the month of January, states that "the weather has, except in the South Atlantic States, been decidedly colder than usual in America, especially from the Missouri Valley to the Middle and Eastern States. Many observers mention it as the coldest month for many years. On Mount Washington the minimum temperature registered 46° below zero on the 27th; at Denver, Col., on the 9th, 29° below, the coldest ever known there."

— THE third and concluding part of Volume XXX. of the "Transactions of the Linnean Society" is entirely occupied by Mr. Bentham's revision of the sub-order Mimoseæ. In his introductory remarks he points out the difference between the values in different cases of the characters on which different classes and genera are founded. Thus he remarks that the genus *Cassia* and the order *Compositæ* resemble each other in these respects—that both are perfectly isolated; the pistil and seeds are uniform in each; the variations in the corolla are scarcely more marked in the one than in the other; and the androecium and fruit present, if anything, more important diversities in *Cassia* than in *Compositæ*; in fact, on purely abstract principles, the latter have as good a claim to be included within the bounds of a single genus, as the former. And yet, because there are 10,000 species of *Compositæ*, and only 350 of *Cassia*, the latter has been almost universally treated as a single genus, while the former is divided into genera varying between 750 and 1,200.

SPRAYS FOR THE HAIR.

THAT natural flowers in the hair have a far more pleasing effect than artificial ones is almost too well known for me to draw attention to. They would be much oftener employed, I have no doubt, were they not apt to flag when not mounted properly, and so the general idea is that they last but a short time fresh when placed in the hair. If, however, a little care be taken with the mounting, they will look quite as fresh at the close as at the beginning of the evening. Blooms for this purpose should always be mounted on wires, and a little damp Moss bound in with the stems to keep them fresh; that is, if the flowers selected have short stems, such as Orchids, Camellias, &c.; but, if the stems be of moderate length, the end of the spray can be inserted in a little glass tube, such as is used for button-hole bouquets (the hook being removed), which can be easily concealed in the coils or braids of the hair. The shape of the sprays change, of course, according to those formed of artificial flowers; but I always like them best of rather a long form, and as light and graceful as possible. At this season, some of the best flowers for this purpose are obtainable; as, for example, Orchids, Camellias, Eucharis, Cyclamens, Hyacinth pips, Lily of the Valley, Roses, Spiræas, Stephanotis, Snowdrops, Azaleas, and many others which space will not allow me to enumerate.

A Floral Wreath for the Hair.

I saw two sprays a few days ago which I admired very much at the time, and I shall endeavour to describe them as they may be useful as a guide to some of your readers. One was composed of a Eucharis, pink Hyacinth pips, blooms of Stephanotis mounted singly, pink Heaths, Lily of the Valley, and foliage; the other of a white Camellia, scarlet Pelargonium pips, Snowdrops, and very small sprays of white Lilac, and Ferns. The flowers in these sprays, save the Eucharis, Lily of the Valley, and Pelargoniums, could not be obtained during the summer months; but there are many others then to take their places, such as Roses, Jasmine, Gardenias, Stephanotis, &c. Blooms of the scarlet Ixia, which are to be obtained during May, rank amongst the most effective of bright scarlet flowers for mounting for this purpose. Ferns, or any other foliage that is used for mixing through the flowers, should be cut from plants that have been grown in a cool house; but there are many leaves and fronds perfectly hardy which work in well in these arrangements.

A. HASSARD.

Fowls and Insects.—A member of the Potomac Fruit Growers' Society speaks of the guinea-fowl and turkey as the best destroyers of noxious insects in gardens and on the farm. We have never seen any bird to exceed quite young turkeys in their active hunt in gardens; and chickens are exceedingly useful—the hen, to prevent scratching, being confined in a coop.

THE INDOOR GARDEN.

A CUCUMBER AND WINTER PLANT HOUSE.

Is it practicable to have a Cucumber and green house combined; the Cucumbers to be grown from April to September, and bedding-out plants from September to April, the latter being on a platform over the Cucumber bed? About what width should the house be, and would a double flue answer—that is, a flue with two branches, running along each side of the house into one chimney? I have a quantity of bricks, and also fuel.—JUNIUS.

[Your correspondent will find no difficulty in growing in his house, as he proposes, Cucumbers from April to September, and then devoting it to bedding plants for the winter. He will merely require some ordinary garden frames to accommodate the bedding plants from the commencement of April until the time for bedding-out has arrived. I should recommend a house having an inside measurement of 12 feet in width, and 20 to 30 feet in length, according to the particular requirements of the case. A flue to branch off towards each side as it enters the house, and unite, and enter the chimney-shaft at the other end, will not answer, as it would draw altogether on either one side or the other, or, more probably, not at all. To guard against any escape of gas, the furnace should be built outside the house, and just clear of its wall. Here, also, to regulate the draught, should be fixed a damper. The furnace should stand in a corner at one end, so that the flue from it can enter the house in a straight line, and be carried down one side across the opposite end, and back on the other side to the chimney-shaft, which should stand in the opposite corner to the furnace. The flue should be 9 inches in width inside, and a foot above the ground level, where it enters the house, rising gradually all the way round to where it enters the shaft, at which point it should be 20 inches or 2 feet in height above the ground. A flue so made is certain to draw well, without which, any attempt to heat by this method is useless. Under every joint of the flue-covers should be placed broad strips of stout hoop iron, to prevent the mortar, with which the joints are filled, dropping through. There should be a space of 1 inch between the flue and the outside wall all round, in order to utilise all the heat. The doorway of such a house must be at the end midway between the furnace and the chimney, and should open upon the path down the middle of the house; this path may be 3 feet wide, with a broad shelf overhead to economise space; on each side of the path there should be a 4½-inch brick-built pit, the exterior walls of which should leave an inch space between them and the front of the flue, thus leaving between the pit and the walls of the house all round over the flue a space of 17 or 18 inches. In winter, the temporary stage for the plants can be made to cover this space, as well as the surface of the pit, leaving it a little open, so as to allow the warmth of the flue to ascend when it is required to be used in damp or frosty weather. These internal pits should be level inside, and carried up to within 2 feet of the glass at the outer or opposite sides to the central path. I am presuming that the house will be built without side lights, and will consist simply of walls and a span roof. The top course of bricks in the pits should be set in good cement, or they will always be liable to become loose. Whilst the Cucumbers are in, the pits may be filled with tan, or a mixture of stable-manure and leaves, the bottom-heat from which will greatly assist the plants and save fuel. The alternate lights on each side should be made to slide, in order to afford ventilation. This will be found to be a cheap and useful house, and will answer the purposes mentioned. It will be still further improved, as regards ventilation, by having half-a-dozen openings, each 12 inches by 18, in the outside walls, on each side, a little above the level of the flue; they can be closed by flaps, made of inch board, hinged at the top, or by slides made of similar material.—T. BAINES.]

CROSSING CYCLAMENS.

MANY now cultivate the Cyclamen persicum, and, as the best way to keep up a yearly succession of plants is to raise a batch of seedlings annually, the importance of fertilising with a view to gain improved types will be at once apparent. The best time to fertilise the blossoms of the Cyclamen is during the early part of the month of March, but it may be done as late as April. The later it is done, however, the less the chance of obtaining the desired result, as all flowering plants are more or less fertilised by the agency of insects during the late spring and summer months, and the access of any of these to the flowers may upset all the calculations of the operator. Crossing should be done when the sun shines, and the first business is to select the parent flowers. The pollen parent should possess undoubted good qualities that it is desirable to transmit to the progeny—such as large blossoms, fine-shaped, or vividly-coloured

flowers. The operator should take hold of the stem between the thumb and forefinger of the left hand, just below the flower, with the thumb-nail of the right hand rap against the side of the bloom, and the pollen will be found lodged on the thumb-nail of the left hand. The seed parent should possess a good habit of growth and well-marked foliage; these qualities are indispensable, and the pollen should be applied to the blossoms, fertilising not more than six, which are ample to produce seed—probably Mr. Little would not impregnate more than two or three. The operation of applying the pollen is one requiring to be done with some care—the stigmatic organs are extremely delicate, and will not admit of any rough usage. The pollen should be gently applied to the stigma, and it will be found that at least a small portion has adhered, which is all that is required. Some growers are of opinion that it is not advisable to cross the ordinary white form of *C. persicum* with a deeper-coloured flower, except to obtain variety; the aim should be rather to keep them distinct, and improve each variety separately. If a flower combines good shape and high colour, but an indifferent habit, it may be used as the pollen parent, crossing with it another coloured flower possessing good dwarf, regular foliage; and the result will be, in most instances, an improved habit, combined with fine quality of flowers in shape and colour. Flowers emitting an agreeable perfume should be crossed one with the other, in order to increase and perpetuate this desirable property. The seed parent should not be overloaded with pods—not more than six blossoms on a large plant should be allowed to seed; if a greater number are retained there is danger of the seed being small, and the plants obtained from it, in all probability, will be found wanting in that vigour which is at all times an important item in obtaining seedlings. After fertilising the flowers intended to carry seed, all others should be removed, and the plants placed in a somewhat shady part of the greenhouse. It has sometimes been objected that certificates should not be given to fine forms of the *Cyclamen persicum*, on the ground that they cannot be propagated; the old practice of dividing the corms being well nigh abandoned by cultivators. On the other hand, cultivators like Mr. Henry Little state that any one variety, especially if artificially fertilised with its own pollen, will reproduce itself with almost unvarying exactness. The first position is unsound and impolitic, because it leads to the inference that new plants and flowers should be recognised only so far as they possess a commercial value and can be put into circulation. The second position is mainly a correct one, but it is not always reliable, unless great care can be taken to isolate the plants to be propagated by seeds, and then not to be absolutely depended on. An illustration in point was furnished in Mr. H. Little's fine collection of *Cyclamens* at the last meeting of the Royal Horticultural Society. Mr. Little fertilised with his own pollen a pure white variety of excellent qualities, and obtained from it some sixteen or so seedlings. All but one were reproductions of the seed parent, with slight variations, and this was of a pleasant pale pinkish-rose hue, in other respects an exact counterpart of the seed parents. Mr. Little supposes some fugitive pollen from another variety with coloured flowers affected the colour of this member of the progeny, but it is perhaps open to doubt whether such a surmise is correct.—“The Gardeners' Chronicle.”

Cool Orchids.—We are about to make a collection of cool Orchids, and I think of commencing with about a dozen good sorts; but before obtaining them, will you kindly tell me what kinds are the best for my purpose. They will have a temperature not lower than 50°, except perhaps during very severe weather. The house in which they will have to grow is fully exposed to the sun and shaded with tiffany.—PALMER. [You cannot do better than obtain the following cool-growing Orchids as a commencement, viz.:—*Masdevallia Veitchii* and *Lindenii*; *Odontoglossum Alexandræ*, *O. luteo-purpureum*, *O. nebulosum*, and *O. pescatorei*; *Sophranitis grandiflora*; *Oncidium macranthum* and *O. cucullatum*; *Disa grandiflora*; *Lælia anceps* and *autumnalis*. These will all do well in a moist atmosphere that is not allowed to sink below 50° in severe weather. During hot weather keep the thermometer as near 60° as possible, and give plenty of air night and day. They should never be allowed to get quite dry at the root, and plenty of water should be thrown on the floor during dry frosty weather.]

Making Cuttings without Joints.—In your issue of the 16th ult. I observe an answer to a correspondent on the above subject, in which Mr. J. Muir states that it is not necessary when preparing the cuttings to cut them closely beneath a joint. Now, having been in practice many years as a propagator, of course I can speak from experience, and I quite agree with him as regards the cuttings of such soft-wooded plants as *Verbenas*, *Fuchsias*, *Petunias*,

&c.; these do not require cutting immediately beneath a joint; but does he mean to say that a *Pelargonium*, either zonal or fancy, will root as well or as quickly without being cut closely under a joint? If so, I must differ from him. For years I have had to keep up a supply of our choicest zonals, as well as tricolors, bicolors, and other varieties, and I have tried them both ways. I have put in an equal number side by side, and have given them precisely the same treatment, except the preparation of the cuttings, and I have been compelled to come to the conclusion that the non-jointing system will not do for *Pelargoniums*. My experience teaches me that if there is any wood left below the joint they will not root until that wood has decayed up to the joint, and in nine cases out of ten where the extra wood has been left they will not root at all. With such a percentage as that it would never do to risk the propagation. I send you a cutting that has been inserted so that the soil covered two joints; you will see that it has rooted at each joint, but you cannot see a single fibre protruding between the joints.—E. G. OTTEWELL, Woolwich.

Top-dressing Azaleas and Camellias.—I do not think that Mr. Baines (see p. 257) need apprehend that anybody would think of removing the top soil from an Azalea, if its roots were packed together on the surface in the way which he mentions. I am well aware of the evil which would result from such a practice; not only in the case of the Azalea, but also in that of all other hard-wooded plants. What I advocated was surface-dressing as a means of inducing roots to keep near the surface; and I certainly had no intention of advising that a mass of surface-roots should be removed to make way for others. I therefore repeat what I have previously said, that Azaleas are benefited by a surface-dressing, or by any other treatment that will bring roots abundantly to the top. I am inclined to think that Mr. Baines did not give the Camellias on which he experimented a fair chance of illustrating the good which follows careful top-dressing, “when he surface-dressed them each season for some five or six years.” The result would certainly have been different had the top-dressing been put on the first season, and allowed to remain undisturbed for the next five or six. It is when the roots find their way into a suitable surface-dressing, and are left there to feed and work in peace and quietness, that the benefit derived from surface-dressings becomes evident.—J. MUIR.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Himalayan Rhododendrons.—Dr. Moore writes to us to say “Our Himalayan Rhododendrons are grand at present, but getting too high for the structures they thrive best in. What a pity they are not a little hardier.” True; yet how valuable they are for those who wish to plant conservatories in the picturesque style, and what treasures for warm temperate countries like California and parts of the south of France!

Standen's Manure.—If this be applied occasionally to *Dracænas* and *Crotons* it will cause them to colour beautifully. It is not necessary to have the pots full of roots before using it, as a sprinkling given shortly after potting will cause the leaves to colour from the first. When the pots are full of roots, and the soil is exhausted, it will keep the plants growing where it is impossible to shift into pots of a larger size. Sulphate of ammonia is useful for the same purposes.—R. P. B.

Colax jugosus.—In addition to the unique aspect and beauty of the flowers of this, as yet, rare Orchid, they have the further recommendation of being marvellously persistent. It is now nearly two months since we (“*Irish Farmers' Gazette*”) alluded to its being in flower in the Glasnevin collection. We have seen it again there this week, and the flowers look as fresh and lovely as they did then; even the snowy purity of the white sepals is not in the least dimmed.

Bertolonia Houtteana.—This is said to be a plant of great beauty. It was raised from seed by Mr. Van Houtte, of Ghent, but we are not informed from what source the seed was procured. During the last season it was exhibited at numerous shows in Belgium, and was universally admired, and gained several gold medals. It is reported to be of the easiest cultivation under a bell-glass. There is no description of the plant in Otto's “*Garten Zeitung*” from which to quote, beyond that it is stemless, and the sparkling colours of jewelled foliage defy imitation.—H.

Potting Bedding Geraniums.—I think there is little use in being particular about placing bedding Geraniums in the centre of the pot, when they are potted off singly. By placing the plant against the side of the pot, 100 may be potted in the time which it takes to place sixty in the centre. Placed at the side they do not, it is true, look so neat, but this is of no importance, as it matters little how bedding plants are set, provided they are effective about the middle of May, and my own opinion is that plants start away more freely with their roots at the edge of the pot, than at a distance from it.—M.

Imantophyllum miniatum.—This is a remarkably fine and free-blooming plant, that makes a good specimen, when well grown, for room or other indoor decoration. It requires little attention for several months in the depth of winter, and if it be grown freely, and is carefully tended in summer, it will stand under a stage without injury, and require but little water, the frost being excluded. If not over-potted the previous year, it will, by giving it a temperature of about 60° at night, throw up its flowers in about three weeks. A plant here in an 11-inch pot, treated in this way, has at present eight strong flower-stems, which have from twelve to seventeen blooms each. Plants in 6-inch pots, with half the amount of flower-stems, would be, I think, very useful.—A. HENDERSON, Thoresby Park.

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATION.

Gold Services.

UPON an oval table, which was 21 feet long and 10 feet broad, and which would accommodate twenty-six persons, it was proposed to place a very large silver-gilt epergne with three branching arms, and also two handsome silver-gilt tazzas of a very ornamental character. There were also, for use if required, three beautiful gilt dessert services, each consisting of four similar dishes, the services being of the several heights of 8, 10, and 13 inches. With ornaments of this character at disposal, it becomes the duty of the table-decorator to make the floral decorations subservient to the plate, and to take care that the materials and colours used are such as will contrast with, and set off, the metal-work. With this object in view, it was evident that all yellow flowers and fruits must be avoided. This was no great hardship, so far as flowers were concerned; but it was a different matter with fruit, since it struck out Oranges, bright rosy Apples, and Pines, which make an effective display on a large table. As scentless blue flowers are scarcely to be had at this season of the year, and as so few of them at any season show well under artificial light, it left nothing to choose from amongst bright colours (exclusive of the indispensable white and green) but crimson and scarlet; and, as the latter would not afford such a striking contrast to the gold as the former, it was determined that crimson and white should be the colours used. The construction of the dinner-table permitted the insertion of ten

A Graceful Table Decoration.

plants through its leaves, at about 2 feet from the edge, and at intervals of 3 feet. It was, therefore, resolved that plants of *Dracæna congesta*, each about 15 inches high above the rim of the pot, should be put through the table; this having been done, the table-cloths were laid, and zinc trays filled with Moss were arranged in a ring around each plant. The sides of these trays were hidden by fronds of *Polystichum aculeatum*, inserted diagonally into the wet Moss, in which were placed alternately trusses of white *Azalea* and of *Monte Christo Pelargoniums*. The arrangement, when finished with some fronds of *Maiden-hair Fern*, presented the appearance shown in the accompanying engraving. Had the table not been prepared for pots to be put through it, I should have selected dwarfier plants of the *Dracæna*, and I should have bent a few fronds of common *Fern* over the edge of the pots to hide them, and have arranged around each pot a ring of plants of *Cyclamen persicum*, alternately crimson and white. It will be noticed that the foliage bore an unusually large proportion to the flowers in the arrangement here illustrated; but this was done designedly, because of the desire to show off the gold plate to the greatest advantage. At the same time, even if there had been no service of this kind on the table, I do not consider that any apology need be made for arrangements like this, since I would always much rather see an excess of foliage than the too common excess of flowers upon dinner tables. The oval space within the ring formed by these ten groups left ample room for the three larger portions of the service already referred to, the floral decoration of which I will not now describe. Of the dozen smaller dishes, ten were selected, and one was placed mid-way between every pair of *Dracænas*, two of the tallest being opposite the middle of the table, and the four

shortest being on either side of the *Dracæna* at each end of the table. It must not be supposed that the uniformity of the ten groups of *Dracænas* resulted in a monotonous or formal effect; on the contrary, the perfect similarity of the floral decorations served as a foil to the irregularity in size of the gilt dishes between them. And this diversity was carried still farther by placing in them a variety of dull-coloured fruits, such as *Russet Apples*, *Easter Beurré Pears*, *Bananas*, *Figs* (dried), *Almonds* and *Raisins*, *Filberts*, *Walnuts*, *Brazil* and *Sapucaya Nuts*, and *Olives*. Thus each gold dish was supported on either side by plenty of foliage, and the combined oval ring of decorations and fruit formed an effective setting around the three large central ornaments.

W. T. P.

BUTTON-HOLE BOUQUETS.

THE bouquets now exhibited in the florists' windows are for the most part composed of a *Rose-bud*, *Gardenia*, or flowers of that class, which, at this time of the year, are expensive; a bouquet made of them being seldom sold for less than eighteen-pence or two shillings; their high price certainly deters many, who would otherwise do so, from purchasing one every day, and this fact induces me to say a few words in favour of the employment of more simple and less costly flowers for this purpose. A few days since, I saw some bouquets, arranged with flowers of the latter class, exhibited for sale on a florist's stall, together with others of a much more expensive character, and the cheaper kinds were by far the most effective. One was composed of a small fresh-looking frond of a *Fern*, similar in appearance to the *Common Bracken*. This was placed at the back, and against it rested a spray of *Deutzia* in bud, and through this were worked a few *Hyacinth* pips of a very delicate shade of pink, the whole being finished off with another spray of *Deutzia*, which had the blooms fully expanded, and was so arranged that the little sprays of blooms drooped downwards, and formed a pretty finish. No *Fern* fronds were used in the construction of this little bouquet, save that mentioned, the foliage consisting solely of the small leaves of the *Deutzia*. Another bouquet was made of lavender-coloured *Hyacinth* pips, *Snowdrops*, a couple of *Fern* fronds, and sweet-scented *Geranium* leaves; at the back was a *Fern* frond, similar to that in the previously-described arrangement, and against this rested the *Hyacinth* pips and *Snowdrops*, the latter being mounted so that they drooped outwards, whilst twined amongst the whole was one spray of *Maiden-hair Fern*. Another charming bouquet was made of *Lily of the Valley* and its own foliage only; and one also of white *Hyacinth* pips of a large size and *Maiden-hair Fern*, the white *Hyacinth* pips looking, at a little distance, very much like *Stephanotis*. There were many other examples, but I think those I have described will show that, by the exercise of a tasteful judgment, most effective little bouquets can be made of simple flowers. I drew attention, some little time ago, to the usefulness of the different varieties of the *Hepatica* for button-holes, and they also may be classed amongst the numerous varieties of simple flowers.

A. HASSARD.

Violets in Paris.—A certain linendraper announced that from the 23rd of March to the 1st of April he would, as in former years, present a bunch of *Violets* to every customer who applied to him. The consequence was a large number of persons were to be seen on the *Boulevards* with *Violets* in their hands or button-holes, and the public imagined that a thorough *Bonapartist* manifestation was organised. The *Bonapartists* cleverly selected the 15th of August, a fête for French Catholics, as the fête of the *Napoleons*. The churches are then filled, and all France has the air of praying for the Imperial family. In the evening there are fireworks in honour of persons bearing the name of *Marie*, and the *Bonapartists*, of course, set down all this expenditure of gunpowder to the account of the *Napoleonic* dynasty. The *Violet* being also appropriated as their emblem, they have confiscated to their profit one of the most popular fêtes in France, and one of the most favourite flowers. There seems a determination, however, not to tolerate this monopoly, and for some days ladies of all parties have been wearing *Violets*. The idea deserves to be encouraged, for, in spite of historical precedents, it is too bad to see flowers, the gift of the Creator, turned into a party badge and made the vehicle of political passions.—“*Times*.”

Primroses for Table Decoration.—I was once at a loss to decide with what I should fill the glass in the middle of a centre piece. Cut flowers and fruits were denied me, as I was instructed to make use of some growing plant for the purpose—either a *Fern* or a very dwarf flowering plant. As I was walking through the reserve garden my eye caught sight of a beautiful root of common *Primrose*, in full flower, with good dark healthy foliage. I got it up, lined the inside of the glass dish (so that no sand or soil could be seen) with *Selaginella denticulata*; put in a little damp silver sand; then the plant; surrounded it with sand, and finished it off by covering all over underneath the foliage with green Moss, and this arrangement, simple as it was, chanced to be very much admired by all who saw it.—H. N. P.

THE FRUIT GARDEN.

HARDINESS OF MUSCATS IN FULL LEAF.

I THINK I may say that possibly few Vineries have cost as little for fuel up to the flowering period of the Vines as our Muscat-house here has done this spring. It was started about the middle of January, the heat being turned on regularly at six or seven o'clock a.m., and turned off again at two p.m. for the first month. Afterwards, it was not turned off till six o'clock, and for the last fortnight it has been left on till ten p.m.; and this rule has been adhered to strictly, except in a few instances when the heat was turned on for an hour, when the fires were made up, as a precaution only, against frost. I cannot say exactly how much fuel has been burnt on account of the Vines, as the same fire heats other houses; but I feel sure that I speak within safe limits when I state that not a shovelful of coals has been expended on them for more than twelve hours out of the twenty-four, on the average, since the house was started till now. Some idea of the saving in fuel effected in that time may, therefore, be formed. The Vines are just on the point of coming into flower, and, within the last fortnight, the temperature in the morning has been as low as 48° on ordinary occasions, and once at 45°. Previous to this, it had often been as low as 45° and 42°, while during the day it has been the same as usual for Muscats. The weather has been very dull this spring, or they would doubtless have been in flower before this time. As it is, I do not think that they are really more backward than they would have been had the night temperature been kept 20° higher all along. The Vines are in the most luxuriant health; the bunches long, sturdy, and well spun out, and the wood short-jointed and hard. Not a trace of insects can be seen, though the Vines have neither been scraped nor cleaned in any way for years. Possibly few, if any, have subjected Muscats to such temperatures voluntarily; for I never knew anyone who would not have felt real alarm if their Muscat-house fell even to 65° on a cold night, when the Vines are in flower, or thereabouts, while 75° was considered the orthodox minimum. Of course, I do not maintain that it is at all needful to subject Vines in full leaf to a night temperature of 45°. Fifty degrees is a safe minimum, for, with a heap of leaves inside the house, scarcely any fire heat is needed to sustain that degree; but the fact that the Vine will stand such, or perhaps even lower temperatures, with impunity, is sufficient to show how utterly groundless have been our fears in former times concerning the effects of a low night temperature, and how erroneous the belief that a high temperature was necessary to the perfect fertilisation of the flowers.

J. S. W.

Peach and Nectarine Enemies.—Can you name the enclosed insect, which I send in two stages of development? It has ruined the Peach blossom, as you will see by the shoots which I send. The trees on a south wall are completely spoiled, while those facing the east have escaped pretty well. The insects are extremely few, which makes the amount of damage done by them surprising. They appear to me to be a species of minute beetle, and jump like a flea. This kind of insect has never made its appearance here before, and, I trust, may never do so again, as a greater pest could not possibly be imagined as far as Peaches and Nectarines are concerned.—H. [The insects sent are two beetles—one a *Haltica* or Turnip flea (*Thyamis ochroleuca*), and the other *Latridius minutus*—but I greatly doubt if either of these is the real culprit. The mischief done to the Peach blossoms is very distinct. In some of those sent there is a good-sized hole eaten through the calyx into or out of the interior of the opening bud, and on tearing open the fresher of these there are indications of some gnawing creature having been at work inside. Neither the ovary nor stamens are touched, the base of the pistil only being a little excoriated, but the chief mischief has been done on the green fleshy part of the inside of the calyx just below the point from which the stamens start. This has been all gnawed and excoriated, and remains moist like a fresh wound, and this fleshy part is larger, and thicker, and more swollen, than is natural, so much so, that at first sight one might mistake a glimpse of one of them for the ovary beginning to swell. No doubt the irritation produced by the insect gnawing this part has set up a morbid action, which has swelled the part in the same way that a gall is produced. The fresh excrement of the insect was there, but no caterpillar. It seems, however, most consistent with what we know of other bud feeders, that an egg has been laid in the bud, which has produced a caterpillar which has done the mischief, and when ready to pass into the chrysalis state has crawled its way out of the, as yet, not quite opened bud and fallen to the ground, there to undergo its metamorphosis. It is much to be wished that our observant correspondent should gather, if still in time, a few of the buds that are not yet pierced and put them in a tumbler with a little earth, not too

dry, at the bottom, covering the mouth of the tumbler with something to prevent the escape of the perfect insect when it comes out; then we should know with more certainty what is to blame for the mischief.—ANDREW MURRAY.]

Apricots in Bloom.—In spite of the continued cold winds the Apricots here are in magnificent bloom; a large tree of the Moor Park was in full flower as early as the 21st of March, the blooming being accelerated by the fact that the tree is growing on the south side of the cottage, and enjoys the permanent shelter of a 20-inch projecting eave. On the eastern side is a large plant of the Early Shipley, and this, on Good Friday, had not a single flower-bud expanded in that aspect, but a considerable extent of the growth that had turned the corner on to the south side was in full bloom. So much for the difference in aspect in promoting earliness, even on the same tree. It would be well if trees of this delicious fruit grew on every poor man's cottage where the situation was suitable; there are few wall fruits more easily cultivated or, as a rule, freer or more general bearers, and excellent aspects now occupied by miserable Vines or useless and unprofitable creepers, might be made to produce beautiful fruit in great abundance. It would be of the greatest benefit if some one could discover a remedy for the frequent decay of large branches; it is very annoying to have the form of a fine tree almost destroyed from this cause and not have the power to prevent it. In some gardens it is necessary to replant the Apricot wall every few years; and such grand old trees as the one at Malshanger Park, Basingstoke, are, indeed, rarities.—A. D.

Insects in Vineries.—Will you inform me what the insects sent are; and what I must do to get rid of them from my Vineries, where I have just discovered them in large numbers.—ROBERT HARVEY, *Derwent House, Little Eaton, near Derby.* [The name of the minute insects sent is *Achorutes purpurascens*. They belong to the Spring-tails, or *Thysanura* (*Poduridæ*), a class of creatures that their monographer, Sir John Lubbock, places, we think with justice, between the Crustacea and the Insects. Other authors regard them as true insects, and rank them among the Neuroptera, near the May-flies, &c. Curtis drew attention to some of these *Poduridæ* being injurious to the Potato. We have seen the small white species (*Lipura fimetaria*) busy browsing upon Carrots, although it is right to add that the Carrots were in an unhealthy state from the attacks of the larvæ of the fly *Psila rosæ*, but, at the same time, it is also right to note that they were not feeding on any injured or decaying part of the Carrots, but at the healthiest part, or thick end of the root. There they browsed away, and their work looked as if the surface of the Carrot had been shaved or rasped away, leaving a fine, clean, fresh surface. They are very minute, and he must be a good observer who, without entomological training, notices them at all. Those sent are, with a few older exceptions, only about half grown (a twenty-fourth part of an inch in length), when they get full grown they will be a twelfth part of an inch in length and much darker in colour. As the mischief done by these creatures has been very little studied, our correspondent will render good service to horticulture if he will note all particulars regarding them and their proceedings for the general good.—ANDREW MURRAY.]

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Black Alicante Grape.—I would advise all amateurs to grow this fine Grape, which ought to have been called the Gardener's Grape; here just now it is still hanging, black as Sloes, and fresh and plump. It is certainly the prince of late Grapes. Lady Downes keeps longer, but not so attractive, and is apt to scald; but Alicante knows no disease, and is always in excellent condition.—R. GILBERT, *Burghley.*

Top-dressing for a Vine Border.—Will one load of turfy loam from a pasture, one load of rotten manure, two cwt. half-inch bones, and one sack of small charcoal make a good compost with which to dress an inside Vine border?—AN AMATEUR. [The compost just named will answer perfectly. If the Vines are old, and the roots far from the surface of the border, remove the old inert soil down to the roots and lay the compost directly over them; if they are young vigorous Vines, and the roots are nearer the surface, top-dress in the ordinary way.—DAVID THOMSON, *Drumlanrig.*]

American Crab Apple (*Pyrus coronaria*).—A more beautiful object than this, when in full bloom, early in spring, it would be difficult to find. Why is it we do not oftener find it in cultivation? Its ordinary height says the "Gardeners' Monthly," is from 10 to 18 feet, with a bole of from 5 to 6 inches in diameter, but trees of it are sometimes found in old cultivated spots, which measure from 25 to 30 feet in height, with a bole of from 12 to 15 inches in diameter. Its clusters of rose-coloured blossoms, of large size, its beautiful foliage and its fragrance, make it an object worthy of attention.

Three Good Late Pears.—Allow me to recommend the three following Pears as excellent late varieties, which may always be depended upon in this locality, and come into use in the order mentioned, and give a succession of ripe fruit from January to May, viz.:—*Beurré Sterckmans*, *March Bergamot*, and *Madame Millet*. The former is very prolific and of exquisite flavour. *March Bergamot*, although not so delicate in texture as the other two, is, notwithstanding, very excellent when other Pears are scarce; it also possesses a rich *Bergamot* flavour, which is particularly refreshing at this season of the year. *Madame Millet* is the latest Pear with which I am acquainted; it comes into use in April, and continues plump, juicy, and rich through May.—T. O., *The Gardens, Wilton House.*

THE FLOWER GARDEN.

HARDY HYBRID BEGONIAS.

It may interest some of your readers to know that now is the best time to provide themselves with tubers of these beautiful and easily cultivated plants, which only require to be allowed to start into growth in small pots in a cool house (as they dislike and resent any kind of forcing), and, about the middle of May, to be turned out of the pots into a well-prepared bed in the garden, filled with rich light friable soil, in which they will grow rapidly, and soon make fine bushy plants, and begin to produce their bright showy blooms about the middle of June, from which time till they go to rest, about the middle of November, they continue to bloom almost without intermission. The flowers are almost invariably produced on long foot-stalks from the axils of the leaves in bunches of three, consisting of the large and handsome male flower in the centre, and a smaller, but equally bright, and longer-lasting female flower, on each side. About the commencement of September, when the nights begin to get chilly, the plants should be lifted with good balls, and put into good-sized pots, when, for the next couple of months, or more, they will form most acceptable ornaments for the conservatory or the drawing-room table. The hybrids to which the above remarks especially refer are those raised by Mr. V. Lemoine, of Nancy; and, as the parents from which all his seedlings originally sprang were the hardy variety, *B. Veitchii*, and the beautiful-foliaged *B. Pearcei*, nearly all his hybrids partake of the hardy nature of the one parent and the ornamental foliage of the other, while the blossoms are nearly all modifications of, and most of them improvements on, those of the first-named parent. I should specially recommend the following varieties, which I know to be really distinct and beautiful, and with which I may safely say none of your readers who invest in them can fail to be pleased:—1. *C. Camoens*; 2. *C. Glijm*; 3. *corail-rose*; 4. *mas-todonte*; 5. *rubens*; 6. *velours*. The tubers travel quite safely by post in a tin box, and are offered at a very moderate price. Mr. Lemoine also offers two new varieties for the first time this season, named respectively *Molière* and *Cornéille*, the latter often producing semi-double flowers. His fine double scarlet-flowered variety named *Monstruosa*, of which a woodcut and description were given in the fourth part of the last year's volume of the "*Revue Horticole*," has not yet been sufficiently multiplied to be distributed; he hopes, however, to have sufficient stock to be able to do so before the summer of next year.

Belgrove, Queenstown, Co. Cork. W. E. GUMBLETON.

***Campanula tridentata* var. *Saxifraga*.**—This belongs to a group of dwarf species of the section characterised by having five recurved bract-like appendages on the calyx. It grows about 6 inches high, each stem bearing a solitary flower about an inch in diameter, and as much in depth, of a pretty purple-blue colour. The radical tufted leaves are linear-spathulate, and about 2 inches in length. It is a very desirable hardy species for the rockery or border. It succeeds best in a light turfy loam with a mixture of leaf mould, and is easily propagated from seed or by division. Although there are several species of this group, all of them dwarf attractive plants, none of them have yet got into general cultivation. The one in question is figured in Regel's "*Gartenflora*" for February

of this year, which is the only coloured portrait of any of the group that we have seen. De Candolle, in his "*Monograph of the Campanulaceæ*," gives plain figures of three or four of them. They are natives of Asia Minor, the Caucasus Mountains, &c. On account of *C. tridentata* having formerly been regarded as a distinct species, and different botanists having adopted diverse names to designate the species, some confusion in nomenclature may probably ensue. De Candolle, in the work cited, employs the name *Biebersteiniana* for the species. *C. Adami* is scarcely distinguishable from our plant. Dr. Regel speaks very highly of *C. tridentata* as a hardy free-growing ornamental species, which bears the winters of St. Petersburg without injury.—H.

THE GREYISH BAMBOO.

(*BAMBUSA VIRIDI GLAUDESCENS*.)

THIS Bamboo, of which the accompanying is an illustration, has been proved to be a very hardy and free-growing plant in the gardens about Paris, and it will probably make a more vigorous growth and prove a more beautiful object in warm situations in this country than any other kind of Bamboo. As isolated specimens in sheltered glades in the pleasure ground, or in snug open spots near woodland walks, its appearance would be highly ornamental. Its stems grow to a height of 12 or 13 feet, and are about 5 or 6 inches in circumference. This variety was introduced in about 1846 by the French Admiral Cécile, and is believed, from the resemblance it bears to other plants from Northern China, to have come originally from that part of the world. Independently of its graceful foliage and elegant shape, which render it valuable for purposes of ornamentation, there can be little doubt that it may be turned to practical use in other ways. Its propagation, as is the case with all kinds of Bamboos, is rather difficult, and takes a long time. It can hardly be effected except by means of suckers, which, when the plants are vigorous, are developed in large numbers. As these suckers have a very marked tendency to push growth obliquely, this disposition should be taken advantage of; in fact, they should be bent down layer fashion, in order that a larger number of roots may be

developed; but, as the latter are formed slowly and with difficulty, separation from the parent stool must be effected with care, and the young Bamboos must not be taken up until they have rooted well. The soil that suits the Bamboo best is a rich, consistent, light, and silicious one, with plenty of vegetable matter in it.

SPRING FLOWERS.

WE can never have too many of these "gems of earth," that "come before the swallow dares, and take the winds of March with beauty." They ought to have a place in every garden, however small; they should fringe the lawn, and ornament the shrubbery borders; and, if they peep up here and there on the fresh grassy turf itself, in sheltered nooks and sunny corners, or on outlying portions of the pleasure grounds, so much the better. By the irregular margins of woodland walks or drives, and in other wild situations, they are peculiarly attractive, and a single afternoon in autumn spent in dropping a few seeds, or planting a few common hardy bulbs in such positions as those just indicated, will be the means of producing charming glimpses of bright colour where otherwise there would be none.

The Greyish Bamboo.

Primroses, Blue Bells, Forget-me-nots, and Wood Anemones may, perhaps, be naturally plentiful in such places; but this should by no means prevent us from gilding the margins of our shrubberies with Crocuses and golden Daffodils. Unfortunately, experience shows that it is difficult to naturalise Crocuses; their fleshy corms are the favourite food for mice, which greedily devour them at every opportunity. In the meadows near Nottingham, however, the common purple *Crocus vernus* defies those little pests, which is accounted for by the meadows being inundated with water for months together during winter and spring. The Daffodil defies all its enemies, for both its roots, leaves, and flowers are fatally poisonous to them, and neither mice nor cattle will touch them. It is one of the best and brightest of all spring flowers for naturalisation, and it is sufficiently robust to establish itself in all kinds of soils and situations when once introduced. Of Crocuses, which are amongst the loveliest of the young year's gifts, many of the most striking kinds are unknown in our gardens. The best collections with which we are acquainted are those of Major Trevor Clarke, the Rev. Mr. Harpur Crewe, and Mr. Ellacombe; whilst Mr. Barr possesses a great number of species and varieties from different climates in his grounds at Tooting. Among those now in flower there are several forms of *C. mosiacus*, including *luteus*, *aureus*, *sulphureus*, and *sulphureus striatus*, all yellow, the last having its outer divisions streaked with brownish-purple, and *lacteus*, a pretty and distinct form, of a milk white colour. The rich orange-yellow brown-streaked *C. susianus* or *C. reticulatus*, as it is frequently called, is also now in beautiful condition. This last is a distinct plant from the Crimea, and is very hardy. The Scotch *Crocus biflorus*, with its thin grassy leaves and pearly purple-streaked buds, is well worth culture, as it is very hardy and a most profuse bloomer. *C. Sieberi* is a pretty little species, which varies from a clear lilac-purple to a nearly pure white, some of the forms being delicately striped or feathered. This plant is figured in the "Botanical Magazine," t. 6,036, where it is described as a native of Greece, and where it is stated that the *Crocus veluchensis* of Herbert, a native of Morea and Transylvania, differs from it chiefly in the orange colour of the throat being wanting. The pretty little species which Mr. Barr grows under the name of *C. veluchensis* is nearly white. *C. sulphureus* is a clear sulphur-yellow, and quite distinct from other yellow-flowered kinds. *C. Wildeni* is white, with a purple base; and *C. Wildeni* var. *dalmatica* has the inner petals white and the outer ones purple. The following Squills are likewise just now in perfection, viz., *Scilla bifolia*, with brown foliage and intense purplish-blue flowers; *S. amoena*, differing from *S. bifolia* in the foliage, being greener, and the flowers of a deeper blue; *S. bifolia alba*, with white flowers; *S. bifolia rosea*; *S. bifolia major*, or *grandiflora*, foliage green, and flowers large and rich blue; *S. præcox* in the way of *S. bifolia*, flowers light blue; *S. sibirica*, ranging from intense deep blue to light sky-blue; *Narcissus Pseudo-Narcissus* var. *nobilis*, crown yellow, perianth sulphur, is now blooming freely; *N. pseudo-Narcissus Telemonius* is a bold flower, with a deeper crown than the last. This is the single form of the large double-yellow Daffodil, so well known in gardens and fields, and stated by some to become single when growing wild, and to retain permanently its double form only in cultivation. Mr. Barr has repeatedly selected from beds of this large double Daffodil (*N. Pseudo-Narcissus Telemonius plenus*) flowers all but single, the only evidence of duplication being a solitary petaloid segment in the centre, but these have always reverted to the perfect double form. Mr. Barr informs us that he has had three large beds of it, collected from the fields in Kent, Herts, and Lincolnshire, under cultivation in his grounds, at Tooting, for several years, and not a solitary bulb among some thousands shows the slightest symptoms of becoming double. The Lincolnshire form of the *Pseudo-Narcissus* appears to be a stronger grower than those found in Kent and Herts. The rich purple and gold-tinted *Iris reticulatus* is just now one of the most showy of all spring flowers, and its blooms last a long time after being cut, and they are most delicately perfumed. This plant ought to find a place in every warm sunny herbaceous border; but it flowers at least a fortnight earlier, and its blooms are fresher if it has the shelter of a cold frame. Among the most beautiful of all spring-blooming plants are Primroses, the double white, lilac and sulphur being now very effective. Of all the double Primulas that known as Golden Plover deserves a place on every sunny border; its flowers are of a rich yellow, and in quantity look like golden rosettes. The Dog's-tooth Violets are also now very effective, one, a large white-flowered variety, having apple-green foliage richly blotched with dark purplish-brown. This is the *Erythronium album grandiflorum* of some gardens, and is a perfect gem in its way, well worth a place amongst fine-foliaged plants apart from its snow-white flowers. The old but still rare *Puschkinia scilloides* is just now in bloom and is very neat in habit, with erect spikes of white star-like flowers, each segment having a stripe of sky-blue

down its centre. These are but a tithe of the lovely spring plants now in bloom in good collections, for, as will be seen, we have said nothing of the dwarf Phloxes, Hepaticas, hardy Cyclamens, Violets, Aconites, and a hundred other old-fashioned flowers which require but little attention after they are once planted. B.

ERYTHRÆA MUHLENBERGII.

THIS new hardy annual belongs to a group of plants, remotely allied to the Gentians, the majority of kinds in the group producing rose-coloured flowers. *E. Muhlenbergii* grows from 12 to 18 inches in height, and has opposite, oblong-spathulate-shaped leaves, erect flower-stems, with terminal cymose clusters of bright rose-coloured flowers, with yellow centre from 1 to 1½ inches in diameter, and produces a succession of bloom, which, Messrs. E. G. Henderson state,

Erythraea Muhlenbergii.

retains its beauty in a cut state for several weeks. Its profuse flowering, neat growth, and richly-coloured blossoms, distinguish it as the most effective species in the class to which it belongs.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Sedum amplexicaule.—I think this will prove a charming variety for carpet bedding. It differs considerably from *S. Lydium*, *S. glaucum*, and *S. acre*, as the growth is not so obtuse, but rather resembles that of a minute *Portulaca*, creeping closely, and with compactness, over the surface of the soil. The base of the growth is comparatively hard-wooded, but it can be propagated freely from the young shoots. The foliage is in colour a pale glaucous green, and would offer a beautiful contrast in panel bedding to the rich lines of the *Alternantheras*.—D.

The Blue Winter Aster.—In Mr. Hayes' extensive glass garden at Lower Edmonton, the plant known in collections of hardy plants as *Stokesia Cyanea* is extensively grown for its winter-flowering qualities. Usually it flowers so late in the open air that we never enjoy the flowers. Mr. Hayes' plants, being indoors at the flowering season, receive no check, and go on flowering from October to March and April, the blossoms now on the plants being small and weak compared with those they yield in autumn. It is a valuable winter flower, and quite distinct from any other to be had at that season.—R.

Wintering the Pampas Grass.—The effects of the severe winter are now beginning to be seen about here as spring advances. Several of my neighbours who like to see all their plants in a neat state during the winter had the decayed foliage clipped from their Pampas Grass early in autumn, leaving the stems and crown quite bare. It now happens that very few, if any, of those so treated are able to grow, having evidently been killed by the cold and exposure. The decayed wood or leaves of many plants would, if left untouched until the plant is about starting into growth in spring, save the life of many a valuable plant.—A. B. G., *Nofts*.

Anemone palmata.—I have now in flower in pots this pretty bright yellow Anemone raised from dried roots, but, without doubt, it would be even earlier from roots that had not been lifted. The leaves are tri-lobed, and grow on very short stalks, at present not more than 1 inch in length. Flower-stems 4 inches in height, supporting two successional blooms which spring out of a leafy sheathing. The flowers are about 1½ inches in diameter, and in appearance are like a loose *Cineraria*, having an outer layer of petals, and an inner row placed immediately between the interstices of the others. The flowers expand early in the day, but close up a few hours after noon.—A. D.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Kitchen Garden—Sowing Broccoli, Lettuce, &c.—A sowing should now be made of Broccoli for autumn and winter use; it is better to sow a little now, and again later on. It frequently happens that, in a very mild winter, the plants intended for late use come in earlier than they are wanted, leaving a blank which the second sowing will fill up. The following kinds, which were enumerated in the list of vegetables given some time back, will afford a succession:—Backhouse's White, Snow's Winter White, and Williams's Alexandra; these, with Walcheren and Veitch's Autumn Giant Cauliflower, which two latter, with good management, will keep up till Christmas, and will be found to last until late in the spring. Dress the seed, as previously advised, with red lead to preserve them from birds, as a failure in this sowing of these important vegetables would cause a blank in the crop. A little more Lettuce should now be sown (Cos and Neapolitan Cabbage), as also small salads and Radishes; by sowing these things a little at a time and often, a continuous supply may be relied upon, notwithstanding extreme dry or wet seasons, in a way that cannot be done where the sowings are made at longer intervals. Ground that has been occupied by winter Cabbages, Coleworts, &c., should, as it becomes vacant, be dug; if it requires trenching, bury the stalks and refuse leaves of the preceding crop in the bottom of the trench as the work proceeds. This is even better than removing it to the refuse heap, as it slowly decomposes in the ground, affording acceptable food for the roots of future crops. The dry cold weather we have had for some weeks has had the effect of bringing the soil into condition for cropping; where the land is heavy and retentive that which was dug during the winter will be much benefited by being again turned over with the digging fork previous to cropping; the sun and air acting upon it, after being thus loosened up, will pulverise and render it much more suited to the requirements of the tender roots of germinating seeds. When the land is thus brought into a fine tilth, even the most hardy vegetable will progress in a way not possible when the soil is in a hard lumpy condition. Keep the hoe going in dry weather amongst existing crops of Cabbages, Winter Spinach, early Peas, and Beans; the object ought to be not to allow a weed to get an inch high, and they are destroyed with one-tenth the labour whilst thus small. Red Cabbage and autumn-sown Savoy should now be planted, and, as these are no better for being grown extra large, 18 inches apart in the rows, and 2 feet asunder between the rows, will be sufficient space for them.

Asparagus.—Where new plantations have to be made it is now the proper time to do so. Many amateurs are deterred from attempting the cultivation of this vegetable under the impression that the preparation of the ground is too costly an affair. If new soil and manure are introduced, wherewith to make the beds of a depth of 4 feet or so, as some advise, it becomes expensive; but such is not necessary to secure Asparagus good enough for ordinary use. If the ground is well trenched, and liberally manured, the dung being got down as low as the soil is stirred, and a depth of 2½ feet can be secured without reaching the raw cold sub-soil, it will answer; where a greater depth can be had, all the better, but it is not altogether necessary. Where the land is sufficiently drained, I prefer planting on the level to the ordinary system of beds with deep alleys; the old method of growing this vegetable so close (four rows on a 4 feet 6 inch bed) is a mistake; let the rows be 2½ to 3 feet apart; the produce will be much finer, and the plants last longer at this distance. In planting, cover the crowns with about a couple of inches of fine soil; the roots should never be allowed to become dry, as this is likely to injure them, or prevent them growing altogether. I prefer one-year-old plants to the two-year-old ones often used; those who are disposed to raise their own plants and wait a season can sow the seeds at once, in the beds, in shallow drills, the same distance apart as recommended for planting, thinning the plants out as required. If the weather is dry after planting give water; keep the ground free from weeds, but do not crop between the rows with anything else, as it only impoverishes the ground, and is more loss than gain.

Slugs.—It is often said that slugs and bad gardening are generally found together; and such is the case, yet I have seen gardens where the cultivation was so good that by constant stirring the surface-soil a weed was scarcely ever to be met with, and still these pests existed in thousands so as to make it almost impossible in the spring to get anything they feed upon to grow. Peas, Lettuce, Cauliflowers, Cabbage, or anything they will eat, are destroyed in the most provoking manner. Dusting the crops with soot and lime is more or less effective whilst the weather is dry, but when showery, it is washed off as fast as applied, and the dustings may be repeated until the remedy has as injurious an effect as

the evil it is intended to check. Where such is the case the whole surface of the ground should receive a dressing of lime. There is no better time for applying this than at the early dawn—on one of those mild damp mornings we often get in April—at which time they may often be seen so thickly on the ground as scarcely to admit of a foot being put down without treading upon them. Four or five cwt. of lime will be sufficient for an acre of ground. It should be prepared by spreading it thinly out on a damp floor until it has absorbed as much moisture as to reduce it to a powder. The way to apply it is to procure a box as large as can be carried under the arm, and then sow it by hand in the same manner as sowing Corn broadcast. In this way a man will, in a short time, go over an acre of ground. To be effectual the whole garden should be thus sown over. It must be observed that it is only on those damp mild mornings that the slugs will be out in number. If the air is at all dry or frosty, instinct teaches them to keep under cover, but if a favourable day be selected, and the job carefully done, more of these pests will be killed by one dressing in this way than would be destroyed by a whole season's work with partial measures, nor is the lime wasted, as it acts beneficially on the land.

Strawberries.—These will now require attention. First go over them with the hoe, stirring the soil betwixt the rows. If there are any small weeds it will destroy them, and if any of larger growth, they must be removed. After this the Strawberries should at once receive their spring dressing of stable manure. That which has lain together a few weeks will be in the best order. This should be put on a couple of inches thick, the whole of the ground between the plants being covered. The manurial portion will get washed in with the rains, the straw will be left quite clean, and in a condition for keeping the fruit from getting soiled with heavy rains. If applied at once, there is plenty of time for the straw to get thoroughly cleansed and sweetened by exposure to the weather; in this respect it will be just as good as the new straw that is sometimes placed on just before the fruit is ripe, and it has the advantage of acting as a manure just at the time when it will benefit the crop, and serve as a mulching which prevents the undue evaporation from the soil of the moisture stored up during the winter, and of which these shallow surface-rooting plants stand so much in need whilst the crop is swelling. Nothing can be more unsuitable than the mulchings of Grass mowings sometimes used. These are naturally cold; in addition to which, whatever seeds are in them will germinate, filling the ground with Grass, which is much more difficult to deal with in a kitchen garden than annual weeds.

Shrubberies.—In many gardens the shrubs are often met with in a most unsatisfactory state, in some instances never having been thinned out from the day they were first planted; and, where sufficient time has elapsed, it is no uncommon occurrence to find them all grown together in a thicket, instead of standing clear of each other, so as to allow every plant space to assume its natural habit of growth, and where they have not been allowed to encroach one on another; the equally objectionable practice of keeping them cut in until the whole has much the appearance of a meadow covered with large haycocks. Now, if, instead of this there had been timely thinning carried out, whilst the plants were not yet too large to move, the result would have been infinitely more satisfactory. If there is no use for the superfluous plants elsewhere, it is much better to destroy the least valuable. Where good shrubs, like the Holly, the Rhododendron, or the Aucuba, are standing with a coarse-growing common Laurel the latter will encroach upon and shortly smother the whole. Hesitate not, therefore, to cut it out at once. It is better to have three good plants than four starvelings. The present is the best time to prune whatever is required amongst evergreens, but wherever the knife is required it should be used very sparingly, and only to reduce any straggling branches. Do not attempt any pruning that will destroy the natural habit of the plants, or at all tend to give them a formal appearance, for this is worse than allowing them to grow in what may be termed a wild state. Many varieties of shrubs, that have been allowed to get into an unsightly condition by overcrowding, may with advantage be headed down to within 2 feet or so of the ground; common and Portugal Laurels especially will be much improved by this, and will soon form good heads.

Annuals.—These should now be sown in the open borders; they are not nearly so much grown as they used to be since bedding plants came so much into fashion, yet there are numbers of very beautiful things amongst them, some even that cannot be dispensed with. Sow Mignonette in sufficient quantity, as it is invaluable for cutting. Nemophila insignis, Convolvulus minor, Calliopsis, white and purple Candytuft, Clarkias, Collinsias, Godetias, Love-lies-bleeding, Eschscholtzias, Ice Plant, Sweet Peas, Nasturtium, Virginian Stock, Schizanthus, Gilias, Helichrysums, and Lupins. These are a few hardy annuals that are worth a place; do not sow the seeds too thickly, and cover about half an inch with sifted soil and wood-

ashes mixed, if the latter are at hand, or a little charred earth, as these keep off slugs.

Gladiolus.—A portion of the stock should now be planted, especially where these beautiful flowers are in demand for cutting; these early-planted bulbs will furnish flowers that will be succeeded by others planted later on. If possible, give them a place where there is a fair depth of good soil, neither of a clayey nature nor yet light and sandy—either extremes of which they do not like. I have generally found disease to attack them most where the land was very light; they like the soil moderately rich, and it should invariably be well pulverised.

Pits and Frames.—Now sow for planting out later on the following half-hardy annuals:—*Rhodanthe Manglesii*, *Phlox Drummondii*, French and African Marigolds; *Tropæolums*—*T. canariense*; *Zinnias*, and *Ipomæas*; and the following tender annuals for indoor culture:—*Celosias*, *Thunbergias*, *Globe Amaranthus*, *Balsams*, and *Cockscombs*. These should be sown in shallow pans, well drained, in a mixture of fine sifted loam three parts, leaf mould two parts, and a little sand, just covering the seed, after which, press the surface with the bottom of a flower-pot, so as to make it a little firm, in which state the soil will not dry so soon, and consequently not require so much water before the seed germinates, which, with some seeds, is liable to cause decay.

Houses.—Peaches that have set their fruit should now be well syringed every afternoon, to keep the foliage free from insects, and assist the fruit to swell. See that the soil is sufficiently wet, not only near the surface, but down as far as the roots go; many a crop is injured or lost from want of attention to this matter. Attend to the tying of *Pelargoniums*, *Calceolarias*, and similar plants; and keep a good look out for aphides. When these are found, at once fumigate, not allowing them to increase in quantity before they are molested, in which case the difficulty of destroying them is much greater, besides the injury they do the plants. Lilies now growing will require more water, and should be kept near the light in a cool house.

Cinchona or Chinchona.—Mr. Markham, in a lately-published "Memoir of the Lady Ana de Osoria, Countess of Chinchon and Vice-Queen of Peru," wishes to prove that the name cinchona, applied to Peruvian bark, should be altered to chinchona. The knowledge of the efficacy of Peruvian Bark was undoubtedly brought to Europe in the year 1640 by the Countess of Chinchon, on her return to Spain with her husband at the expiration of his term of office as Viceroy of Peru. This lady, during her residence there, was attacked by tertian fever, and cured by the use of Peruvian bark. On the return of the Count and Countess to the Castle of Chinchon, the Countess, who had brought with her a supply of the precious bark which had effected such a wonderful cure upon herself, "administered Peruvian bark to the sufferers from tertian agues on her lord's estate in the fertile but unhealthy vegas of the Tagus, the Jarama, and the Tajuna. She thus spread blessings around her, and her good deeds are even now remembered by the people of Chinchon and Colmenar in local traditions" (p. 45 of the Memoir). Though from time to time during the succeeding hundred years powders of the Peruvian bark were imported into Europe, no scientific account of the tree was published until 1740, in which year De la Condamine published a description and figure in the Memoirs of the Academy of Paris for 1738, under the generic name of *Quinquina*. This communication contained also an account of the history of the drug, wherein the name of the Countess of Chinchon was duly mentioned and properly spelt, and on the information obtained from it, and quoted in acknowledgment, Linnæus, in the second edition of his "Genera Plantarum," published at Leyden in the year 1742, founded his genus *Cinchona* in honour of the Countess of Chinchon. The word cinchona, however, has now become settled by the usage of upwards of a hundred and thirty years, and sufficiently recalls the name of the enlightened and benevolent lady to whom Europe owes the introduction of this most useful therapeutic agent.—"London Medical Record."

Epping Forest Enclosures.—In the new Act to extend the time for the Epping Forest Commissioners to make their final report, there is the following provision against any new enclosure:—"Any person who shall, in contravention of any order made by the commissioners under the 5th section of the Epping Forest Amendment Act, 1872, make any enclosure of any land within the said forest not enclosed before the passing of the Epping Forest Act, 1871, or wilfully or maliciously commit any waste, injury, or destruction of vert herbage, trees, shrubs, or other growing things in or upon any land within the said forest to which the order relates, shall be liable to a penalty not exceeding £20, to be recovered upon summary conviction."

HOUSETOP GARDENING.

Or the tens of thousands who daily travel by the numerous high-level lines of railway which penetrate the metropolis, few can fail to be impressed (or rather depressed) by the utter dreariness and ugliness presented, mile after mile, by the housetops among which the train proceeds. The great fire of 1666 caused sad havoc with the high-pitched roofs of old London; and hence the quaintly carved gables and pinnacled domes which distinguish the roofs of so many Continental cities, and not a few of our own mediæval towns, are rare indeed in London. The rebuilding and extensions which followed in later Jacobean and Georgian times unhappily took place simultaneously with the decadence of the picturesque in domestic architecture; and, if truth must be told, in our own Victorian days, the "skyline" of our streets is determined rather by the most economical compliance with the Building Act, than by principles of Art, though in the case of hotels and similar great undertakings there have lately been marked improvements in this respect. There is, however, another aspect, besides the æsthetic, from which to view such questions. More than once, attention has been directed to the waste of space, represented by this vast area of unutilised London roofs. Here and there, at wide intervals as we speed along a viaduct, may be seen a photographer's rickety studio perched against a chimney stack, and perchance a few smoke-stained flower-pots and half-withered shrubs on a sooty flat. All else is abandoned as a watershed for the elements, and a trysting-place for cats. We have been led to make these remarks by a step in the right direction, taken by Messrs. Barr & Sugden, whose new building, erected in King Street, Covent Garden, we this week illustrate with a view, showing how town roofs may not only be utilised, but may be rendered ornamental. For the requirements of their trade in plants, it was necessary to have upon the premises glass erections of considerable size; and, as will be seen by a reference to our engraving, the roof area has been wholly devoted to this purpose. To conform to the requirements of the Duke of Bedford's lease, the roof proper of the premises terminates with a strongly-constructed lead flat, above the third storey of arch-headed windows; and, above this, the conservatory is constructed, a strong trellised floor being laid over the flat roof, and the walls taken up to support the roof of the conservatory. The structure comprises a central Palm or tropical house, 36 feet long, and 18 feet wide, with a lofty arched roof, and two side wings, each 10 feet wide—one for the reception of Ferns, and similar plants, and the other a cool house for bulbs. The hot-water pipes in the Fern department have been furnished with Taylor's patent ventilating zinc boxes, by means of which a continuous supply of fresh air is introduced from the outside, warmed, and then allowed to escape into the house at the required temperature, which, by means of this appliance, is comparatively cool and enjoyable although the thermometer registers 69°. A temperature in the tropical department only 2° higher than this seemed much more oppressive. Considering the exigencies of a London atmosphere, and the requirements of the Building Act, it was determined by the architects, Messrs. Spalding & Knight, of Queen Victoria Street, to apply Howitt's patent to the construction of the roof, which is a combination of wood and iron and which has been skilfully carried out by Messrs. Fletcher & Lowndes, of Great George Street. Both house and conservatory are heated by means of hot-water pipes, attached to a 4 feet 6 inch saddle boiler, set in the basement, some 60 feet below the conservatory, each floor having independent flow and return pipes, which are of two different diameters, *i. e.*, the pipes which convey the water to each floor, and also the returns, are both 1 inch in diameter, whilst on the floors themselves 2-inch pipes are employed, and in the conservatory 4-inch pipes. Although the central portion is curved, straight glass has been used, and the colour of the wood-work is of a light tint relieved with blue. The elevation of the building in King Street is in the Italian style of architecture, and, altogether, the building, with its plant decorations, is an ornament to the neighbourhood. We owe this spirited innovation to Mr. Peter Barr, and doubt not that the good idea he has thus boldly illustrated will spread rapidly, and that we shall in due time see beautiful winter gardens on the tops of private houses.

NEW HOUSE-TOP CONSERVATORY.

THE SETTLEMENT OF VINELAND.

By the Founder, CHARLES K. LANDIS.

IN the year 1861, being then about twenty-eight years of age, and full of hope and courage, I conceived the idea of starting a settlement upon virgin land, near the great seaboard markets of America. I decided upon this location, in order to afford the widest and most certain scope for individual success, alike on account of the markets and of the opportunities for skilled labour in farming, gardening, and mechanics. I selected a tract of about 30,000 acres, or about 48 square miles, in the wildest part of New Jersey, on a railroad which had just been completed, but did very little business. On this land I had no resources but the soil itself; the large timber had all been cut off years before, to supply the New York and Philadelphia markets; there was no coal, no iron, and no great navigable stream—nothing to help by way of commercial speculation. Besides, at that time there was no tide of emigration pouring into New Jersey—it all went West. Before my time, small tracts of land would not be sold to strangers, and emigration to that section was discouraged. I knew, therefore, I had no chance help to depend upon, such as ordinarily allures people to new places, but that whatever was won had to be created by industry; yet I believed that if this could be attracted, and then placed in the most favourable condition for its development and increase, all the disadvantages would be overcome. It was necessary for me to create such a state of things that, when the people were brought together from the commencement, and during the progress of the settlement, and after it had become populous, these people should prosper and be contented. The broad design of the settlement was that it should be horticultural, agricultural, manufacturing, commercial, and educational—one object could not well prosper without the others. The first question to be solved was the labour question. On the 8th day of August, 1861, I went upon the railroad, near the centre of the tract of land, and fixed the spot for the city. It was the highest ground, and near the centre of the tract, upon the railroad which ran to Philadelphia. I decided that all my roads should be wide and straight, and at right angles. I would make up for the want of the picturesque in the straight line and the right angle by requiring trees for shade in single or double rows, according to the width, to be planted along all the roads. The engineer drove the centre stake, I cut down the first tree myself, and the axemen then proceeded. During this time an old backwoodsman came up, and, looking at the surveyor's instrument very curiously, asked me what in the world we could be doing. I explained to him that I had just driven the centre stake of a city; that I would at once proceed to open a street 2 miles long and 100 feet wide; and that in ten years' time, upon the spot where he stood, there would be churches, schools, factories, and dwellings, and thousands of population; and around this city for miles and miles would be stretching orchards, vineyards, and farms. The old man saw from my eye that I was in sober earnest, and as I proceeded he moved off farther and farther, and, when at a safe distance, he said, "Young man, I am now old; I have lived here all my life—my father and my grandfather before me. You can never do this thing." Afterwards he went up to one of the axemen, and confidentially told him to be sure and get his money on Saturday night, "as that young man evidently meant well, but was out of his mind." This old man now lives in the city in a corner plot, opposite the public park. The same week I set a large force of men to work, and it was not long before I had a magnificent avenue opened, 2 miles long and 100 feet wide, along the sides of which I left some of the beautiful forest trees for shade. At the end of the first week I decided to take action upon the labour question. I reasoned that it would not be consistent with the good of the place to have any kind of labour degraded—that it would militate against my interest as well as that of the public. That it would be better for me to encourage all labourers, that they might have hope, energy, and sympathy for my efforts, and be able to live in their own freeholds, in order that their prosperity might be a part of the prosperity of the settlement. When my foreman hired the axemen, they said nothing about the amount of pay they were to get—they took it for granted that they were to have the customary pay of the place, which was two shillings per day in store orders upon the shops in Millville. I decided to stop this entirely; therefore, when Saturday night came, I paid them at the rate of four shillings a day in gold. Then the premium on gold was light. I afterwards raised their wages above this. When they received their pay their amazement was inexpressible. One man objected to receiving money, saying he had never used any, and would not know how to spend it. I told him that it was time for him to learn. I made no explanation to these people, only asked them to save all they could, which they promised to do. The next week they worked with great good-will, accomplished much more, and spoke well of Vineland—the name I had decided on. I then told my foreman to give me the names of all the men who were steady and industrious, and had families. When the names were given to me, I called the

men to me, and told them my designs about the place, and that, as they were steady and good men, it would be well for them to have homes which they could call their own, and that I would allow them each to select 10 acres of land at twenty-five dollars per acre, which they could pay for in a term of years, and that I would furnish them with a carpenter and timber, and help them to erect houses for themselves of a cheap but convenient kind, which they could pay for in the same way. I added that they must have no fear of failing—that they must have faith that I would not take the property away from them, but would give them a deed in fee simple, as soon as the land was paid for, and that I would bind myself to do so in writing. They had faith, and went ahead. On off-days and hours they worked for themselves, and cleared their land. The next season they had their crops growing, and this was the nucleus of the settlement, and the way I solved the labour question. I will remark that every one of these men succeeded, and got his deed, and there was not one with whom I had any trouble. At the same time I erected a plain school-house of timber, and at first employed a teacher at my own expense, until there were enough settlers and pupils to organise a school district. My system or plans upon which I founded the settlement may be classed under two heads—the Material and the Moral. In each contract I required that—1. The purchaser should erect a habitation, not nearer than 20 feet from the side of the street, in the city plot, or 75 feet from the roadside, in the country. This got rid of the greatest evil in new countries—speculation, and it made each colonist labour personally to improve his lot and co-operate with his neighbour, and with myself, for our mutual benefit. It also kept the settlement continually growing, and made the outlands successively saleable. The stipulation about setting the houses back removed them from dust, and induced great attention to the ornamenting of front gardens with flowers and shrubbery. 2. That each person in front of his or her homestead, should plant trees for shade at proper distances apart, within one year. My own engineer set the stakes for the trees. This was to turn the uniformity of straight lines and right angles in the roads to a feature of beauty as well as utility. The trees forming long vistas, in time would become surpassingly beautiful; they would also prevent droughts, and make a harbour for birds, which are necessary for a fruit country. As a protection to roads and affording a grateful shade in summer, we all know their value. 3. The next stipulation was that the roadsides should be seeded for Grass within two years, and kept seeded. This was done to add to the beauty and to economise land which ordinarily was allowed to go to waste; as also to prevent the spread of noxious weeds that had been usually allowed to grow up by the roadsides, from whence seeds spread over the adjacent fields. I employed numerous road-gangs to work, and opened through my land 176 miles of road, and built numerous causeways and bridges. This I did at my own expense. I also laid out squares in certain localities for public ornament, and devoted a park of 45 acres adjoining the city plot for the same purpose. These were intended for fairs, festivals, and public amusements. The marsh land I drained by opening the streams and digging ditches through the centre of them. I dug 11 miles of centre or main ditches, which reclaimed a good deal of the best land, and laid bare beds of material which proved to be an excellent fertiliser. But there were other questions which had to be decided at once, or all this work would be lost in the ultimate failure of the settlement. By the laws of the State of New Jersey, cattle were allowed to run at large, and all persons who improved land were compelled to fence their grounds to keep out their neighbours' cattle. This was a wasteful habit. It involved an immense outlay to begin with; also the cost of keeping the fences in repair and the loss of the manure of the cattle. Upon an estimate, I found it would cost over a million of dollars to the settlers to fence the Vineland tract. To keep the fences in repair would cost ten per cent. per annum, which would be 100,000 dollars, and the loss of interest at six per cent. would be 60,000 dollars per annum. I, therefore, got a law passed, prohibiting all cattle from running at large, and repealing the Act requiring fences to be built, so far as it related to my district. People then kept their cattle in enclosures, and soiled them, as the farmers term it; much to the good of the cattle, the saving of manure, and the saving of capital. It also induced them to cultivate root-crops, which added to their wealth and benefited the land. This almost produced a war upon me from the native Jerseymen, who lived around my property; but they have since seen the benefit of it to such a degree that in all the surrounding counties they have followed our example and adopted the same law. Another important question was the economising of manures and sewage. I introduced earth-closets—simply a sliding box under the seats, and a keg of dry earth. This kept all thoroughly deodorised, and the manure was almost immediately suitable for use upon the land, and at the end of the year amounted to considerable value. In the aggregate, in the whole settlement, its money value was very large. I explained to

the colonists that Nature taught us that nothing should go to waste, that these things should be turned to advantages and blessings, instead of being allowed to foul the air and produce typhoid fevers. I had a law passed making it finable in the sum of two hundred dollars to dig any cesspool that would possibly reach the water level of the wells. The sewage was managed in this way:—The farmers disposed of it by running it in receptacles for liquid manure. In the town it was disposed of by running it through a box holding dry manure, sawdust, and sand; the water would run out clear, the filtering matter would retain the fertilising properties, and after a certain time would be emptied and replaced. The central village has a population of 4,000 people, and as you walk through it no noxious smells will ever assail you. The remarkable health of Vineland is, no doubt, greatly owing to this cause. Other towns in the neighbourhood that live under the old system are greatly troubled with fevers and epidemics. If the same system were adopted in London, you would have something more valuable than all the guano beds of the Pacific to keep up the value of your lands. The saving of life would be very great, and the plan is perfectly feasible.

The next thing I will mention is education. In Vineland we have built some twenty school-houses, consisting of primary and grammar schools; and this year we have built a large high-school, as it is called, at a cost of over 30,000 dollars, for teaching the higher branches of education, which school was opened the 22nd of last August by the President of the United States, and most of his Cabinet. The next step will be to connect with all our schools an industrial and technological branch of education, that boys may be trained in physical industry, and have the sciences, and agriculture and horticulture practically taught to them in their everyday work, step by step, in connection with their studies. When the settlement started, most of my land was found to be in the township of Millville. This was soon found to be an inconvenience, and it was important that the main features upon which I founded the settlement should be made a law. I therefore got an Act of the Legislature passed embodying the main features of my plan, and setting off the most of my territory into a separate township. To this Act I have since got supplements passed as they became necessary. The most important principle is that the entire township is governed by a committee of five men, elected annually by the people. I have had no city charter, no alderman, no imposing body of councilmen. I believe the more the governing body is increased in number, the more is individual responsibility divided and lessened. A system of few legislators, with powers strictly defined, who have to appear often for re-election, is what experience has proved to give the greatest satisfaction. This has secured to us a faithful performance of public duties at the lowest possible rate of taxation. In the progress of the settlement, as the number of members belonging to any religious denomination increased, I gave them land, and contributed money towards erecting churches, showing no favour to any creed, and treating all alike; only encouraging a good style of church edifice as far as possible. We have erected Episcopal, Methodist, Presbyterian, Congregational, Baptist, Unitarian, and Swedenborgian churches; some of them are spacious and fine buildings. The Catholics are now building. For the first few years I contributed to the salaries of the clergy. At the first it was necessary to introduce the cultivation of such products as were adapted to our soil and climate and markets. For the produce most sought after in the markets of Philadelphia, New York, and Boston, our soil and climate were well adapted. These were fruits, such as Grapes, Pears, Peaches, Apples, and berries of different varieties; also vegetables, such as Sweet Potatoes (or Yams, as they are called in England), early white Potatoes, table and field Beets, Onions, Lima Beans, Cabbage, Turnips, Cauliflowers, Asparagus, Pippins, and Melons of different varieties. These all grow to perfection, and ripen early. Our people also raised Wheat, Indian Corn, Grass, Millet, and stock for home consumption, but the other articles were raised to send away. I succeeded in getting the settlers to plant extensive orchards and Vineyards; I think there are now at least 1,500 Vineyards and orchards in Vineland, presenting one of the most beautiful sights imaginable. As produce was raised it came to be necessary to market it; and considering that the colonists were strangers in the country, I employed an agent at my own expense, whose duty it was to take their produce to market, dispose of it, and return them the money, free of any charge for his services. In time, as the colonists became acquainted with business and the markets, this became unnecessary, and I withdrew this assistance. As the settlement grew, people who had capital to invest came to Vineland and settled, for the purpose of residence. I noticed that this capital generally sought investment out of Vineland—in the State of New York and other States, where the rate of interest was seven per cent., instead of six per cent., as in the State of New Jersey. I made an effort to have the law, so far as related to my own township, changed, so as to allow seven per cent. interest, but

failed in the Legislature the first session, owing to the prejudices of some of the members. The next session I was more successful, and the Act was extended to the entire State, much to the advantage of Vineland, and the rest of New Jersey. This alone gave an impetus to industry beyond what many believed possible. After the settlement had so grown as to number some thousands of inhabitants, and had a great deal of produce to send to market, we had reason to complain of the high charges for freight upon our single railroad. I remonstrated with the company, and received from its general manager fair promises about reduction, but these were not fulfilled. I then, with much difficulty obtained a charter from the State Legislature for a new railroad leading direct to New York and Baltimore. After a struggle of five years, I succeeded in getting this new railroad constructed, when there was an immediate fall in the rates upon both railroads. Then more produce was raised, and manufacturers came in, who before were deterred on account of the high rates of freight. The construction of the latter railroad increased the trackage through the Vineland territory, from 8 to 17 miles, adding vastly to the value of property, as well as to the prosperity of the people, and affording new outlets.

There is a material and industrial prosperity existing in Vineland, which, though I say it myself, is unexampled in the history of colonisation, and must be due to more than ordinary causes. The influence of temperance upon the health and industry of the people is no doubt one great cause. The settlement has built twenty fine school-houses, ten churches, and kept up one of the finest systems of road improvements, measuring 178 miles in the country. There are now some fifteen manufacturing establishments on the Vineland tract, and they are constantly increasing in number. Her stores in extent and building will rival any other place in South Jersey. There are four post-offices in the tract. Out of seventy-seven townships in the State, by the census of 1869 Landis township ranked the fourth in the value of its horticultural-agricultural productions. There are 17 miles of railway upon the tract, embracing six railway stations. The amount of products sent away to market is enormous. Her fruits are to be seen in all the large eastern cities, from Philadelphia to Quebec. There is more fruit raised in Vineland than anywhere else in the United States upon the same area of land. To drive through the place over the smooth and beautiful roads, lined with young shade trees, and bordered with green, and past her thousands of orchards and Vineyards, is like driving through the loveliest of parks.—“Fraser's Magazine.”

[The above is but an abstract of a very interesting paper on Mr. Landis's remarkable settlement.]

TREES AND SHRUBS.

NEW CONIFERS AND THEIR SYNONYMS.

MR. MEEHAN seems anxious to diminish the number of nature-stamped species of Conifers by massing several of them into one. According to your impression of March 13, he makes five or six admittedly distinct species of *Picea* to be but one species—namely, *P. grandis*—or, at best, only varieties of it; and he would have added another to the list—namely, *P. concolor*—but hesitates to do so out of regard for the discriminating powers of Dr. Englemann, who considers it to be a distinct species. He, however, concludes that “*Picea bifolia* and *P. magnifica* of Murray, and *P. violacea* of Roetzl, will probably have to go back to *P. grandis*, as *P. amabilis*, *P. lasiocarpa*, and *P. Parsonsiana* have had to do.” I was not before aware that anyone had pronounced such forms as *P. amabilis* and *P. Parsonsiana* (*Pattoniana*, *Lowiana*, or *lasiocarpa*) to be the same as, or slightly altered forms of, *P. grandis*; neither do I think that any qualified botanist will ever pronounce *P. magnifica* of Murray to be the same as *P. grandis*; unless, perhaps, he manages to institute a new and different definition of what constitutes a species and what a variety. In the meantime, however, it is enough for us to know that *Picea Parsonsiana*, *amabilis*, *magnifica*, and *grandis* are nature-stamped species, inasmuch as they severally possess distinctive or peculiar characters, which are almost invariably transmitted to their seedling offspring. The following comparison of their leaves, and their arrangement on the branches, will probably justify a specific distinction:

P. GRANDIS.—Leaves, rather closely arranged, in two double horizontal rows or tiers, on each side of the branches, those composing the upper tiers being from half an inch to three-quarters of an inch long, while those of the under tiers measure from 1 to 1½ inch long, and all of the same width (one-twelfth

of an inch), somewhat linear, on short twisted foot-stalks, blunt and emarginate at the points, grooved from base to point, and of a deep glossy green on the upper face, while the under face is slightly raised along the middle, and striped with two bright silvery bands.

P. PARSONSIANA.—Leaves, thinly disposed, in two very distinct lateral rows on the branches, falcate, or at first spreading, then turning upward and inward, somewhat linear, nearly uniformly long, from 2 to $2\frac{1}{2}$ inches by one-tenth of an inch broad, generally slightly notched at the point, and on short twisted foot-stalks; channelled for about two-thirds their length, but in some instances from base to point, with a distinct and never-failing broad band of pallid stomata along the middle of the upper face; which is of a light green colour, slightly raised, and with two white bands on each side of the midrib on the under face.

PICEA AMABILIS.—Leaves, densely arranged along the sides and upper face of the branches, those on the upper face being generally much incurved, flat, blunt, and evenly notched at the points, from three-quarters of an inch to $1\frac{1}{4}$ inch long by one-twelfth of an inch wide at the point, from which they gradually narrow to a rather long slightly-twisted foot-stalk, deeply channelled, and of a dull dark green on the upper face, while the underside is slightly raised and striped with two broad bright silvery bands.

P. MAGNIFICA.—Leaves, densely disposed along the sides and upper face of the branches, falcate, slightly adpressed and turned upward, somewhat four-sided, linear, blunt pointed, from three-quarters of an inch to $1\frac{1}{4}$ inch long by about one-sixteenth of an inch wide, of a dull dark green above, and striped with two faint white bands below.

Why, then, does Mr. Meehan refer these forms to *Picea grandis*? Are we to understand that they originally sprang from that kind, or that in accordance with his own hypothesis, they are the result of a cross between *Picea grandis* and another very distinct species—say, *P. nobilis*? Considering that *P. grandis* and *P. Parsonsi* each possess peculiar structural characters, which are almost invariably transmitted to their offspring, we must conclude that they are both deserving of specific names. That Mr. Meehan should be at fault in this matter, however, need not surprise us, seeing that both Mr. Gordon and Mr. Murray give, now and then, imperfect descriptions of some of our Conifers. Mr. Murray, indeed, has lately admitted that he cannot distinguish the leaves of *P. magnifica* from those of *P. nobilis*; and Mr.

Gordon, in the first edition of his "Pinetum," in describing the leaves of *Picea grandis* and *amabilis*, entirely overlooks the fact of their being deeply grooved along the upper face; but I am happy to see by the second edition of his "Pinetum," just published, that, in the case of one of these species the mistake is corrected. It is also rather odd that Mr. Gordon, who was the first to popularly describe *Picea Lowiana* (as he called it) should still persist in saying that it has straight leaves, when every one who knows the plant could testify to the contrary being the case. It has most decidedly falcate leaves. Indeed I have only seen four plants of it that had

straight leaves, three of which were growing in the shade of large Elms and Scotch Pines. He also fails to credit it with having a band of pallid stomata along the middle of the upper face of the leaves. And allow me to correct the statement that it is only "found in valleys, or along the alluvial banks of rivers; never as a mountain tree." I have myself gathered specimens of it from trees growing on the high ridges or bluffs, high up on the western slope of the Sierra Nevada Mountains; and I have had hundreds of good-sized plants sent to me to the lowlands of California that were dug out of the steep slopes of the ravines of the Sierra Nevada. GEO. SYME.

Elvaston Nurseries,
Borrowash.

Keteleer's Guelder-Rose.

KETELEER'S GUELDER-ROSE.

(*VIBURNUM KETELEERI*.)

THIS *Viburnum* forms a bushy shrub rarely exceeding 3 feet in height. Like *V. macrocephalum*, to which it is related, it blossoms from April to May. It yields seeds freely, but, in the absence of these, it may be propagated by means of cuttings made of half-ripened wood placed under a cloche. It may also be easily multiplied by grafting, selecting for a stock either *V. lantana* or *V. opulus*, or some of its varieties. Plants of this Guelder Rose should be treated in every respect like those of *Viburnum macrocephalum*.

It is sufficiently hardy to be grown out of doors; but in cases of extreme cold it is prudent to give it some slight protection. A light soil that is dry, warm, and calcareous, appears to suit it best. This *Viburnum* came originally from China, and we owe its introduction to a rather peculiar circumstance. Horticulturists of the present day are aware that the *V. macrocephalum* is with difficulty reproduced from cuttings, and that grafting is almost the only way by which it can be increased. That the Chinese were acquainted with this peculiarity of the plant may be inferred from the fact that some stems of it which were introduced from China were found to be grafted. A few years ago these might have been seen at MM. Thibaut & Keteleer's. The stock upon which this variety was

grafted having pushed growth, M. Keteleer obtained cuttings from it and gave one to M. Carrière, who planted it in the open air, and the following year it produced a dozen clusters of flowers, one of which was the original of the accompanying illustration. M. Carrière remarks, in the "Revue Horticole," in reference to this plant, that although it has been named *V. Keteleeri*, it should, properly speaking, bear the name of *V. Keteleeri macrocephalum*.

POPLARS AND THEIR FOES.

POPLARS constitute a well-known genus of trees belonging to the Willow family (*Salicaceæ*), and are extensively distributed over the northern hemisphere. As ornamental trees, they are cultivated throughout almost the whole of Europe, and in Siberia and other parts of Asia; they are highly valued for their timber. They are remarkable for rapidity of growth, and all of them are well suited for planting in parks.

The White or Silver Poplar.

This, the most valuable species in this country, is a native of northern Asia. It has a tall, erect, and tapering trunk, from 95 to 110 feet high, and from 3 to 6 feet in diameter. Occasionally individuals, more than 30 feet in circumference at the base, may be met with. The branches are slender and rod-like, have a strong upward tendency, and form an elegant crown. The bark is a light ash-grey in colour and smooth, except upon old trees, where it is split and rent in all directions. The leaves are about $3\frac{1}{2}$ inches long, by $2\frac{1}{2}$ broad, and depend from the small twigs upon long slender petioles, which are covered with a white, soft, woolly material. They are alternate, sharp-pointed, ovate, and serrated, and of a bright green colour; the under surface of each leaf is covered with a short cotton-like substance. The leaves wither and fall off early in autumn. The flowers are amentaceous or in the form of catkins, and appear early in spring, before the leaves begin to expand. The male and female catkins grow upon distinct trees, and consequently, when individuals of one sex stand isolated their seeds are sterile. The male flowers consist of a number of loosely connected florets, each with eight stamens. They wither and fall off as soon as the pollen is emitted. The female catkins do not differ much in appearance from the male. Each floret contains an oval-pointed ovule, a very short pistil, and a quadripartite stigma. The seeds, which are ripe in June, consist of small, oval, curved capsules each of which contains a number of small, black, oval seeds, furnished with woolly tufts. The culture of this species of Poplar has greatly extended in Great Britain during the last few decades. It grows rapidly, and is of great value in districts where there is a scarcity of timber. In Asia, its timber is largely used in house-buildings, for which it is said to be well adapted, being durable, and little affected by atmospheric influences. When the tree is young the timber is soft and white, but, when old, it becomes hard and of a brownish hue. In this country it is chiefly employed for making wooden utensils and trays. The White Poplar thrives best in a rich soft soil, with a surface stratum of moist humus. The best method of propagating it is by cuttings or scions, as the development of young trees from seeds is a very tedious process. The cuttings should be planted in March in a damp soil, and the scions about the end of autumn. The young roots should be carefully protected from frost. This species of Poplar is very common in Germany and Italy. It seems, according to report, to have been a favourite ornament of the parks and pleasure-grounds of the ancient Romans.

The Common or Black Poplar.

This well-known tree is found in almost every part of the United Kingdom. Its leaves, which are 3 inches long, by 2 inches broad, are almost triangular in form, thick, and tough in texture, and grass-green in colour. It is a very rapid-growing tree, and in a rich fresh soil frequently rivals the Oak in size. The bark is ash-grey, but upon the branches and young trees it is of a light yellowish tint. The leaf-buds are sharp-pointed, thick, and glutinous, and emit a strong balsamic odour when bruised. Bees are very fond of this tree, and it is said that they obtain material for wax from its leaves. The truth of this belief is very questionable. A few Black Poplars, however, should always be planted in the immediate vicinity

of gardens where bees are kept. The Black and White Poplars are also admirably adapted for nurse trees to young plantations and shrubberies, especially in the vicinity of towns. The Black Poplar is well adapted for planting in damp boggy soils, and it thrives exceedingly well upon the banks of rivers and lakes. The wood is soft, tough, and difficult to split. The larger roots are beautifully veined, and, in some places, are used for inlaying work. Upon the Continent, the wool found upon the seeds is not unfrequently used, with the addition of some cotton, in the manufacture of bed-covers, mats, gloves, and stockings.

The Aspen.

The Aspen (*Populus tremula*) is of very little value, except as an ornamental tree. The wood is soft and useless, and is not even adapted for fuel. The leaves are ovate and serrated, and depend upon petioles so long and slender that the slightest breath of wind sets them in motion. The Aspen generally attains a great height and circumference. The trunk is usually from 90 to 100 feet in height, with a diameter of 6 or 10 feet. In the Pessbar Forest, in Hungary, there are several Aspens whose trunks are not less than 110 feet high, and some 15 feet in diameter.

Other Species.

There are several other species of Poplar, chiefly indigenous to North America and Asia. One of the handsomest and most valuable of these is the Balsam Poplar (*Populus balsamifera*), an American species, which has been acclimatised in this country. The leaves are about 5 inches long by 3 inches broad, sharp-pointed, deeply serrated, and of a light green colour. The fresh young leaves of this tree, when applied to external inflammations, are said to produce a very beneficial and cooling effect. When the buds are distilled in spirits or strong brandy, before they begin to expand, a glutinous balsam is obtained, which is said to be very valuable in surgery. The wood of this tree is comparatively worthless; but it has a handsome green foliage, and forms a very beautiful object in the landscape. It is propagated by cuttings, and grows very quickly. It thrives best in a damp mild humus, with a sub-soil of moist boggy earth; if planted in a dry sandy soil, it almost invariably dies. The Balsam Poplar suffers much from the ravages of insects, which pierce the wood. The Laurel-leaved Poplar (*Populus laurifolia*) is a variety of this species. It is a native of Siberia, and is characterised by the smallness and dark colour of its leaves. Besides those, there are still several other kinds of Poplar to which attention may be directed, and amongst which may be mentioned the Grey Poplar and the Libyan Poplar. A very handsome variety of the latter is the *Populus bicolor*, so called from the circumstance of the upper surface of its leaves being white, whilst the under surface is green. The habits of this tree are the same as those of the White Poplar, and it is well adapted for cultivation in this country. The Italian or Lombardy Poplar (*Populus dilatata*) is a native of the plain of the Po. It is distinguished chiefly by its close handsome pyramidal crown. The trunk attains a height of 60 feet, and a diameter of 2 feet. The branches are long and slender, and but sparingly clothed with foliage, which, in form and colour, resembles that of the Black Poplar. This tree still abounds in the plains of Lombardy and Venice, where its timber is extensively used for flooring.

Insects that infest Poplars.

All species of the Poplar tribe are liable to the ravages of insects, of which the most destructive are as follow:—*Chrysomela populi*, which, in its grub state, feeds upon the foliage of the trees from June until August, and passes through the chrysalis stage upon the leaves. It is of a steel-blue colour, and is chiefly found upon Aspens. *Melolontha hippocastani* is scarcely distinguishable from the common cockchafer. *Melolontha horticola* is a very destructive insect, and attacks all kinds of trees and shrubs, of which it devours the leaves, blossoms, and even fruits. Its ravages begin in the month of June. *Cerambyx carcharias* is found only upon Poplars. *Cerambyx populneus* lays its eggs in rents in the bark, whence the grubs bore into the wood. *Chrysomela quadripunctata* attacks not only Poplars, but also Oaks, Alders, Willows, Birches, and Hazels.

JOHN HUTCHINSON, M.A.

A SMALL GREENHOUSE LAMP-STOVE.

A CHEAP and good method of heating pits, frames, and small greenhouses has long been wanted by those who grow a few common decorative plants. Gas possesses great heating power, and is not difficult to manage; but, on the other hand, when it escapes or when combustion is incomplete, it is fatal to plant life. Candles have been used to exclude frost from tender bedding plants in frames; but these, unless used in large quantities, do not throw off sufficient heat for that purpose. One of the best of all appliances of this kind, for heating small areas, has been sent us by Messrs. Dietz, of Carter Lane, St. Paul's; it consists of a strong paraffin lamp, which burns pure rock-oil, and generates no gases injurious to plant life. This little stove consists of a paragon burner, set in the base of a metal cylinder, with a metal in lieu of a glass chimney. A double casing is given to the oil-well, so that the heat of the wick tube cannot be transmitted to the oil. A great heat is generated, and in a couple of hours the temperature of a greenhouse or room can be raised between 20° to 30°. By removing the outer casing, and substituting a glass chimney, the stove becomes a lamp. We give a view of this very useful stove.

A small Lamp-stove.

THE AMATEUR AND THE AURICULAS.

ONE of the pet flowers of amateurs is the Auricula. Happy the flowers which have escaped savants and amateurs; they have not received ridiculous names; they are not tormented, distorted, or subjected to a thousand whimsical exigencies; they blossom in peace. The learned require that the Auricula should be yellow; if it presents itself clothed in any other colour it is pronounced a monster, as double Roses are. Amateurs grant it permission to wear what colours it pleases; but this is only an appearance of liberty. I once saw an amateur in a state of fury. Some Auriculas had been sent to him from I don't know what country: he had cultivated them with care; he had tormented them after the methods most approved of by amateurs; he had deprived them of water, and more particularly of sun and earth, by placing them in a pot, and as I went into his house he was tearing them up, one by one, and trampling them under his feet. I understood, from his broken exclamations, that the Auriculas had avenged themselves for the ill treatment they had received, by not fulfilling the conditions he required and had hoped for. I, however, ventured a few questions to assure myself of the fact, and at the same time to learn what horrible offence could have been committed by these poor flowers, which appeared to me to be decked with the richest colours, and to be in perfection. He continued his execution, pronouncing upon everyone his motives of judgment and condemnation, before he crushed it under his feet. I will place you in a condition to do as I did, and to derive instruction; that is to say, to learn what are the duties of the Auricula towards its cultivator, and how it transgresses them. He took up one of a beautiful velvety blue. Its stalk is too short, said he, and he crushed it. To this succeeded another of a rich velvet-brown, with a white circle which is called the eye; its stalk is too long—crushed. A velvet-orange; the flower is not exactly round—crushed. A deep purple-velvet; the bouquet has only eight flowers; it ought to have twelve—crushed. A velvet-olive; the eye slimy (that is to say, it is slightly tinged with the olive colour)—crushed. A velvet-yellow; the eye does not occupy a third of the circumference of the flower; that is the least it ought possibly to do; I have a friend who requires half—I am more indulgent, but I cannot admit this—crushed. A velvet pale violet; the eye is not exactly round—crushed. A deep violet-velvet; eh! what do you do here? your clou exceeds your paillettes, a pretty thing that! Here I stopped the judge and executioner to request an explanation. Auricula fanciers call the pistils the clou, and the stamens the paillettes. The stamens ought to extend beyond the pistils, and appear alone; it is a very serious thing when the contrary happens to be the case. Whatever may be the colour or the splendour of the flower, a true amateur would scorn to keep such a one in his collection. A hundred charming flowers were thus sacrificed before my eyes. I in vain endeavoured to save them by begging that he would make me a present of them; my entreaty was rejected. "Not at all, not at all; I will give you some others." "But these please me very much." "Nonsense; you are joking!"

"Not at all, I assure you." "I cannot consent that such flowers should come from me; if it were known that I had given them I should subject either my collection or my friendship to animadversion." He was inflexible. Do not imagine that I invent or exaggerate; seek for an amateur of Auriculas, and read to him this passage of my letters. I can assure you beforehand that he will not smile, that he will see nothing ridiculous in it, that he will say his brother amateur was right, perhaps even a little too indulgent. In addition to the florist's lesson, this is a chapter to add to the rights of man. You now know what are the duties of Auriculas, and I hope you will see how to make them perform them.

ALPHONSE KARR.

GARDENING FOR THE WEEK.

Kitchen Garden.

Late Peas.—In the majority of soils these are best sown in trenches made something similar to those for Celery, and I allude to this matter now because I have generally found it to be an advantage to have the trenches prepared a month or six weeks before it is necessary to sow the Peas, especially if the summer should turn out to be dry. In gardens, however, where close and continuous cropping must be adopted, it is often requisite that late Peas should follow Broccoli or some other crops, that cannot be removed till just before the ground is required for the Peas, and, in that case, if it is possible to clear off a row here and there at suitable intervals apart, it will be advisable to do so. In planting the Broccoli, by marking where the Pea rows will come, and at each of those places planting a row of some kind of Broccoli that will turn in during March or April, making some little allowance for the variation of the seasons, this might easily be done. In preparing trenches for Peas, they should be, if possible, from 15 to 18 inches wide and 1 foot deep, and from 4 to 6 inches of manure should be placed in the bottom of them, and thoroughly incorporated with the next foot of soil beneath. Some portion of the soil taken out should then be returned in order that the trench may not be more than 6 inches below the level of the surrounding soil. This will be ample for watering, and deeper trenches only lessen the depth of soil available for the roots of the plants. The thorough and deep incorporation of the manure in the bottom of the trenches is, however, an important matter, as it tends to encourage the roots to descend beyond the influence of heat and drought, and, consequently, they are rendered less liable to the attacks of mildew. Where sticks are easily obtained, tall Peas are better than dwarf ones, and *Ne Plus Ultra*, of tall kinds, and *British Queen*, are still two of the best, and for late use they may be planted in quantities at intervals of a fortnight from the 1st of May till the middle of June. Without wishing to endorse all that has been written in favour of what is called double cropping, in the matter of late Peas I have practised it to some extent in the following way with considerable advantage:—At this season, when we are planting the main crop of Potatoes, in setting out the rows, which are usually 2½ feet, about every 5 yards or so, a space of 3 feet is left vacant for a row of Peas, and in the centre of those spaces the Pea trenches are prepared before the Potatoes are planted; thus when the time comes for sowing the Peas all that is necessary is to set a line and draw a drill 6 inches wide along the centre, plant the Peas 2 inches apart all over the drill and cover with 2 inches of soil. If the weather should be very dry, the drills should be well watered before planting. I have invariably found the rows of Peas amongst the Potatoes to be more productive and more lasting than others in another part of the garden where the rows were placed side by side; but the free and abundant circulation of air on all sides will easily account for this superiority.

Early Celery.—Early sown Celery should now, or very soon, be pricked off into boxes from 2 to 3 inches apart, and be placed in a frame where a little steady bottom-heat can be furnished, and kept close for a few days; checks of all kinds must be guarded against or all labour will be thrown away by the plants "bolting" when they ought to be coming into use. A sowing of Celery should now be made for the main crop in a slight hot-bed. A good red and a good pink kind may be had in *Williams's Matchless Red*, and the *Sulham Prize*, or *Ivery's Pink*. In addition to sowing those kinds in gentle heat, sow a little at the same time thinly in the open air, in the best soil available. If a very warm spot is vacant at the foot of a south wall, sow a row of French Beans, about 4 or 5 inches from the wall, in a shallow trench; they can be easily protected on cold nights in such a position, and will come in at least a fortnight earlier than others sown in more exposed situations. In the neighbourhood of rookeries, rooks and jackdaws are often troublesome at this season, and will, if not looked

after, dig up and carry off Potatoes, Peas, Beans, and other seeds. I never destroy life except it is absolutely necessary, but I am compelled in self-defence to shoot a jackdaw now and then, and to lay it on fresh planted crops outside the walled garden. If a dead jackdaw is laid on the ground, breast downwards and the wings pegged out, I will guarantee no living one will settle on that land again while his body remains in sight. Sow in a gentle heat Basil and Sweet Marjoram for transplanting in the open air in May. These are largely used, therefore provision should now be made for a good supply of them. The roots of Tarragon should also be divided and re-planted; this is apt to go off in wet heavy soil, and, where this is the case, cuttings of the forced shoots will root at this season in heat, and a stock of young plants may soon be obtained. Sow Vegetable Marrow in a warm frame, three seeds in a 48-sized pot, filling the pots only two-thirds full of soil. Allow room for earthing up the plants. A part of the land might be planted by having the hills prepared, and the seeds put in under hand-lights, about the middle of the month, where they are intended to remain.—E. HOBDAV, *Ramsay Abbey*.

Indoor Fruit Department.

Vines.—Fruit on the earliest pot Vines will, in some instances, have been cut during the past week. As soon as it is all removed from one rod it should be thrown out, and another, not so far advanced, substituted. Few Vines are worth keeping to fruit a second time in a pot, as unfruited or maiden canes always give far more satisfaction. When the eyes of any new or valuable variety, which has been fruited in a pot, are likely to be scarce, the plants must be looked after until they are thoroughly matured and ready to cut off. Encourage the growth of late Vines when they seem willing to grow, as no good is derived by starving them in a low temperature, in order to start them at a fixed date. That the fruit may be thoroughly ripe, and in a fit condition for keeping throughout the winter, all Vines should be in growing order by the first week in April. To start early and ripen early is a much better practice than starting late, and leaving the ripening a matter of uncertainty. As Vines break more evenly now than during the short days and long nights, it is not necessary to let the upper half of the rod remain untied and hanging down; but they may be tied into their allotments without delay. Rather than smother any promising piece of young wood of last year's growth with side shoots from neighbouring rods, keep all such well pinched in, especially those not bearing fruit. Indeed, it is generally the best plan to restrict shoots not in fruit to within two eyes from the main stem, and to give those with bunches attached the benefit of more light. The atmosphere about Grapes in the early Vineries may, with advantage to the flavour, be kept in a drier condition as soon as a change of colour is perceptible in the fruit.

Pines.—Much care is still necessary in watering all kinds of Pines so as not to overwater, and thus cause a sour condition of the soil about the roots. When lately-potted plants have been watered, after the operation some weeks often elapse before they need it again; for the second, as well as the first watering, clean water only should be used, as it is not safe to use powerful stimulants until the roots are plentiful at the outside of the ball. Pine stoves directly facing the sun require to be slightly shaded during the warmest part of the day about this time. A thin piece of canvas laid temporarily on the glass when the sun is strongest is sufficient for a time, but by-and-bye shading must be kept continually on, and then it is the best and cheapest way to paint the roof sashes with a mixture of milk and whiting, which should be worked up to the consistency of paint, and put on with a brush upon a hot day, when it dries quickly and firmly, is always neat, and remains on until shading can be dispensed with in the autumn.—J. MUIR.

Flower Garden and Pleasure Grounds.

Of all the coloured-leaved plants used for the decoration of the flower garden during the summer months the most beautiful are the various species of the Brazilian *Alternantheras*, and of these the loveliest and also the most delicate of all are *A. amoena*, and its somewhat improved variety, *A. amoena spectabile*. The entire species, however, are indispensable in the flower garden, more particularly where carpet-bedding is practised. It is generally found to be difficult to induce these plants to grow so as to furnish cuttings during winter and early spring, but if the stock of old plants or store pots are now introduced into a brisk bottom-heat they will rapidly furnish the necessary material for this purpose, and the cuttings will strike root very freely if placed in a close propagating case; and, after being gradually hardened off, will be ready to be turned into the flower-beds by the beginning of June, which is as early as this plant, together with the *Coleuses*, *Iresines*, &c., can be trusted in the open air. Where it is intended to use any of the fine varieties of the garden Beet as an edging to flower-beds, or

in ribbon-borders, &c., the seeds should be sown now, and the plants, when large enough to handle, should be thinned out to a distance of 6 inches from plant to plant; or the seeds may be sown in pans, from which they may be transplanted. The first-named method, however, is the best, as they are not found to transplant well, more particularly should very dry weather set in about the time this is attempted. If a good variety of this plant is obtained, it will be found that there are few, if any dark foliaged plants, which will surpass, or even equal in richness of colour, or which are better suited to special decorative purposes, than this culinary plant. The rich metallic hue of its ample foliage harmonising perfectly with the *Centaurea* and other white-foliaged plants, as well as with the Golden Feather *Pyrethrum*, *Stellaria graminea aurea*, &c. The present is the most suitable time for sowing annual flower seeds of all kinds in order that they may flower throughout the summer months, and this may be done in the open air where they are intended to bloom or in seed-pans under glass, to be pricked out into other pans or boxes, and finally transplanted into the open air; the latter method, on account of the seeds of many varieties being so exceedingly small, is in most cases the most advisable; the comparatively larger kinds, such as the Sweet Pea, the *Tropæolum*, &c., and *Mignonette*, which does not transplant well, may be sown where they are now intended to flower. There are many annual flowers which, on account of their ephemeral character and somewhat weedy aspect, are, to a great extent, excluded from the flower garden. The bedding-out system has also had much to do with this result, and the circumstance, as regards many of them, is not to be regretted; while, on the other hand, there are many varieties which will, as it were, continue to assert their right to a position in every garden.

Select Annuals.

Among these may be mentioned improved varieties of French and German Asters, Ten-week and other Stocks, besides *Mignonette*, which, on account of its delightful perfume, will always be in favour. During the last few years greatly-improved varieties of this plant have been introduced to the public, which are found to be quite as sweet-scented as the old sort. There are also the various and beautiful varieties of the *Phlox Drummondii*, many of which are exceedingly pretty; the *Zinnia elegans*, which of late years has been greatly improved, and is well deserving the consideration it now obtains. Many of the everlasting are also well worthy of cultivation, such as *Rhodanthe Manglesii*, *Helichrysums*, *Xeranthemums*, &c., together with *Dianthus Heddewigii* and its many varieties, the dwarf and beautiful *Candelabra Larkspurs*. Some of the dwarf French Marigolds, such as *Tagetes aurea floribunda* and *Tagetes signata pumila* are, from their dwarf and compact habit of growth, their profuse and long-continued flowering, even valuable as bedding plants. *Gaillardia picta*, *Godetia Whitneyi* and *Dunnetti*, *Linum grandiflorum*, *Viscaria cœrulea*, &c., are all showy and useful annual flowers; while, from the description of the new *Romneya Coulterii*, it appears to be a remarkably beautiful flower, and may probably be found to be useful for the production of blooms for cutting, as well as for the decoration of the flower garden. Among dwarf or trailing annual plants the following will be found valuable. *Abronia umbellata* and *Abronia grandiflora*, producing *Verbena*-like clusters of bloom throughout the summer months, and *Portulacas* of many colours, with double, as well as single flowers. These plants are admirably adapted for a warm sunny border, on poor or light gravelly soil, producing, as they do, throughout the summer months a long succession of truly brilliant flowers. *Clintonia pulchella* is also a very beautiful dwarf-growing annual, producing a profusion of brilliant-coloured *Lobelia*-like blooms, *Sanvitalia procumbens*, is an old favourite dwarf annual flower, which continues to bloom throughout the summer months, the flowers being yellow with a black centre; and there is also a double-flowered variety, in which the black disc entirely disappears. *Leptosiphon roseus* is another exceedingly dwarf and beautiful annual, seldom more than 3 or 4 inches in height, and producing a profusion of terminal clusters of rose-coloured flowers during the summer. It requires tolerably rich soil, but when it can be induced to do well it is one of the most beautiful of annual flowers. There are also several climbing annuals which are found to be exceedingly useful for the summer decoration of the flower garden, in covering trellis work of all kinds, and can be made to form graceful festoon-like wreaths of gay-coloured flowers throughout the summer months. Among the most suitable plants for this purpose are the following, viz.:—The "Morning Glory" or the *Convolvulus major*, and its still more beautiful striped blooms, which it unfolds with the early morning light; hence its trivial though appropriate name. Several of the closely allied species of *Ipomœa* are also well suited to this purpose, together with *Tropæolums*, *Eccremocarpus*, *Lophospermums*, *Loasas*, *Maurandias*,

&c. It is sometimes desirable, during the summer months, to shut out or conceal certain objects which may be considered unsightly or not in character with their surroundings, and this concealment can generally be effected by the use of climbing annual plants, such as the Scarlet Runner, &c. A very effective and ornamental screen may also be formed by such annuals as the *Tropæolum canariense*, *Convolvulus major* and *C. major picturatus*, and the various kinds of Sweet Peas, which should all be sown in one drill, and the plants should have supports as soon as they require them, in the form of stakes such as are used for the taller kinds of Marrow Peas, for the *Tropæolum* and the *Convolvulus* will grow to any desired height, and will ultimately overpower the Sweet Peas, which will, however, come into flower first, and will be succeeded by the *Convolvulus* and the *Tropæolum*, both of which will continue to flower until they are destroyed along with other tender bedding plants by the frosts of October. The effect produced by the gay-coloured flowers of *Convolvulus* and the pale yellow blooms of the Canary-flower, with Sweet Peas of various shades, will be found to be very remarkable and by no means unpleasing. Patches of the more hardy annual flowers may also be sown now on the margins of shrubberies and similar situations wherever there may be found sufficient space for doing so; and the most compact-growing and dwarf sorts should be kept near the front, while taller kinds may occupy the background. Plenty of Mignonette, however, should be used for this purpose, as this plant is not only very ornamental but, on account of its delicious perfume, is very much appreciated.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Orchids.

The East India-house this month should have a night temperature of 68°, and should be allowed to rise to 80° by day in bright weather. In the Mexican-house the night-heat should be 62°, and that by day, if bright, 75°. The temperature for the *Odontoglossum*-house should be 50° at night, and it may be allowed to rise to 60° on bright days, and for the benefit of all freshly-potted plants little air should be given until they have made plenty of fresh roots. Where evaporating troughs are used on the pipes, they should be kept filled with water to create more moisture in the house—treatment which will tend very much to keep the plants from shrivelling. Syringe the leaves of *Aërides* and *Vandas*, once a day, an operation in which great care will be required to prevent the water from getting into the centre of the plants. *Cattleyas* should be watered sparingly until they have made plenty of roots. *Odontoglossum Bluntii* and *Oncidium macranthum* should be liberally supplied with water, and a sprinkling of it over their leaves on bright days will add to their health and vigour. *Disa grandiflora* should be sprinkled with water at least twice a day, an operation which must not be neglected as the weather becomes warmer. Plants of *Dendrobium chrysanthum*, that have made growths 2 feet long, would be benefited by being watered with weak liquid manure once a week. Nearly all *Dendrobiums* enjoy a warm atmosphere while growing, and if kept too dry many of them are subject to red spider. *Pleiones* must not be allowed to suffer from want of water, and as they advance in growth they should be watered with weak liquid manure twice a week. *Masdevallias* will require great care as regards watering until they have made young growths from 2 to 3 inches in length. Many of the varieties will be in flower this month, and we shall no doubt hear of some wonderful varieties occurring in the Harryana section, which is one that should be grown in large quantities, as the colour harmonises so well with that of other Orchids, particularly with *Phalænopsis* and *Odontoglossum*, both cut and otherwise. In the case of plants that have scales on them, no time should be lost in eradicating it before they begin to make growth, for if this is neglected they will not make healthy plants. *Aërides*, *Saccolabiums*, and *Vandas*, are subject to small brown scales, which attach themselves to the edges of the underparts of the leaves, and which are so small as to be easily over-looked. Where these appear, wash the leaves with weak tobacco-water and soft soap mixed together, and applied with a soft sponge; never use a brush. Fumigate often, as it is better to do so frequently than to be compelled to over-fill the house with smoke, which might injure some of the plants. Orchid-houses will now be gay with *Epidendrum atro-purpureum*, *Dendrobium Devonianum*, *D. Wardianum*, *D. infundibulum*, *D. Cambridgeanum*, *D. fimbriatum*, &c., *Leptotes serrulata*, *Lycastes*, *Cypripediums*, *Trichopilias*, *Oncidium leucochilum*, *O. flexuosum*, *Odontoglossum Alexandræ*, *Saccolabium giganteum*, *Phalænopsis grandiflora*, *P. Schilleriana*, *Vandas*, and other kinds.—E. CULLEY.

The Sextus Potato.—This is one of the best late Potatoes grown. It is so disinclined to sprout in spring that it may be kept until June in a suitable place. It is nearly disease-proof, a capital cropper, and so good in quality that it may be described as a rich Potato. There are fifty good sorts I would lose rather than this.—S. H., in "Gardeners' Magazine."

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

MARCH 31st.

Spring Exhibition.

THIS show was fully up to average exhibitions of the kind in former years, and, the weather being all that could be desired, it was well attended. Hyacinths were fairly represented, Messrs. Cutbush, Barr & Sugden, and Carter & Co. being exhibitors in the nurserymen's classes; while Mr. Douglas represented the amateur growers. Messrs. Paul & Son's collection of pot Roses, Mr. W. Paul's Camellias, and Mr. Charles Turner's collection of Ivy in pots, and standard Aucubas profusely laden with brilliant fruit, contributed very materially to the attractions of the exhibition. The Society's conservatory, which is always interesting, is now unusually so, being well furnished with spring flowers, and a magnificent specimen of *Rhododendron Countess of Haddington*, although rather past its best, is still covered with its large waxy white blossoms.

Hyacinths and Tulips.—In both of these Mr. J. Douglas, of Loxford, had well-grown examples; but, as the varieties differed little from those named in our report of the South Kensington exhibition, on March 17th, there is no need to describe them here. In the nurserymen's classes, among the white varieties, the following Hyacinths were in excellent condition, viz.:—*Mont Blanc*, *La Grandesse*, *Madame Van Der Hoop*, and *Miss Nightingale*. Prominent among the blues were *Marie*, a dense and effective variety; *Charles Dickens*, a good bluish-lilac; *King of the Blues*, a fine dense dark blue; *Grand Lilas*, bright porcelain-blue; *Laurens Koster*, a good double blue. Among reds, we remarked *Von Schiller*, a good bright rose; *Macauley*, rosy-salmon; *Cavaignac*, salmon, inclined to flesh; and *Garibaldi*, a bright rosy-crimson. Amongst the Tulips were *Colour Cardinal*, bright scarlet; *Van der Neer*, purple; *Pottebakker*, white; *Keizer Kroon*, golden-yellow, flaked with scarlet; and *Prosperine*, a bright rosy flower.

Stove and Greenhouse Plants.—Mr. J. Ward, gardener to F. J. Wilkins, Esq., of Leyton, had a small but well-grown group, in which were well-flowered plants of *Cytisus racemosus elegans*, a dense-habited variety, with glaucous leaves and spikes of bright yellow flowers; *Eriostemon buxifolium*, a yard high, and 2 feet in diameter, studded with pure white star-like blossoms; a small but wonderfully vigorous plant of *Anthurium Scherzerianum*, bearing four splendid spathes 5 inches in length, and fully 4 inches in width, the colour being bright glowing scarlet; and *Erica M'Nabiana*, about 2 feet in diameter. Mr. G. Wheeler had a smaller group, in which were a good *Erica Lindleyana*; the purple-flowered *Cochlostemma Jacobianum*, with three spikes of purple *Tradescantia*-like flowers; *Imantophyllum miniatum*, bearing half-a-dozen good trusses of showy flowers; *Pancratium fragrans*, furnished with a good truss of bloom; also *Azalea Marie*, a bright rosy-scarlet kind; *Dendrobium nobile*; and the ever-welcome lemon-yellow-flowered *Acacia Drummondii*. Mr. Wheeler had also an effective and well-arranged group of miscellaneous plants. Mr. Ward's *Azaleas* were in excellent condition, and though rather small as exhibition plants, they were well bloomed. The varieties were *A. Borsig*, one of the best semi-double white kinds in cultivation, and very useful for bouquets or wreaths, as its flowers last well after being cut, while the single-flowered varieties fall quickly. The collection also contained *Model*, a kind with clear rosy flowers; *Stella*, a well-known favourite, having large glossy scarlet or crimson-tinted flowers; *Punctata omnicolor*, a striped or variegated variety, in which either red or white predominates; *Roi des Beautés*, a fine semi-double lilac flower, with white edges; and *Madame Van der Cruyssen*, a large rosy-lilac, slightly inclined to be double. Mr. G. Wheeler had a fine little group of *Azaleas*, among which we noted a large crispy-petalled salmon-tinted variety, named *La Paix*, in good condition. The foliage is large and good, and it may be considered one of the best of the salmon-tinted varieties. Mr. J. Child, gardener to Mrs. Torr, Ewell, had six fine plants, among which were the white crisped petalled *A. Marie Vervæne*. The best *Deutzias* came from Mr. J. Douglas, of Loxford, who furnished compact cylinder-shaped ten-year-old plants, about 2 feet high, and very profusely-bloomed, both foliage and flowers being well developed. Mr. G. Wheeler staged a dozen small, but well-bloomed plants of *Clematis*, the plants being trained in a globular form, and profusely studded with large star-shaped purple, blue, or white flowers. Mr. B. S. Williams contributed a well-grown and effective collection of Ferns, Palms, and other fine-foliaged and flowering plants, among which were a narrow-spathed variety of the *Flamingo* plant (*Anthurium Scherzerianum*), very brilliant in colour; *Tillandsia Lindenii*, with elegant grassy recurved foliage, and erect spikes of rich blue Iris-like flowers, having a white eye; a splendid specimen of *Imantophyllum miniatum*, with about a dozen spikes, and a brilliant scarlet white-striped *Amaryllis*, named Mr. Little, with three or four flowers on a scape. Mr. W. Paul, of Waltham Cross, staged a good collection of Camellias in excellent condition, and two stands of beautiful cut blooms; also a stand of his new Chinese *Primula*, named *Waltham White*, a kind which produces stout trusses of large white flowers, of good substance. A well-grown collection of Persian *Cyclamens* came from Mr. James, of Isleworth; and Mr. Little, of Twickenham, had more compact plants of the same, all in the freshest and best condition possible. Messrs. Carter and Co. sent *Coleus Duchess of Edinburgh*; and a crisp-leaved kind, named *Mandarin*; also a bright lilac-purple-flowered variety of the common *Primrose*, named *Lady Adelaide Taylor*, very bright, and well deserving attention. Messrs. Barr & Sugden exhibited a named collection of *Polyanthus Narcissus*. Mr. Charles Turner, of Slough, had a basketful of a new

pale mauve or lilac double Violet, named Lady Hume Campbell, which flowers profusely, the blooms being extra large and deliciously fragrant.

Orchids.—A fine plant of the old *Dendrobium fimbriatum ocellatum* (D. Paxtoni of some gardens) came from Mr. T. Stevens, gardener to Mr. G. Simpson, of Reigate. The plant was fully a yard high, and quite as much in diameter, and bore, at least, fifty drooping spikes of golden-yellow, crimson-eyed or blotched flowers. In Mr. Ward's collection we noted a fine plant of *Cypripedium villosum*, bearing between thirty and forty flowers, and a vigorous plant of *Odontoglossum triumphans*, bearing two spikes, one of which bore five branches and some thirty-six flowers and unopened buds. The smaller spike bore seven finely-formed richly-coloured flowers. This is the best of all the yellow-flowered *Odontoglossa*, and it grows freely in a cool moist temperature. In the same group a well-grown specimen of *Lycaste Skinneri* bore twenty-five flowers and buds, the sepals, petals, and crimson-blotched lip being suffused with bright rose. Mr. G. Wheeler had a fine plant of the old *Epidendrum Stamfordianum* bearing two branched spikes. This plant is remarkable for producing its flower-spikes from the base of the pseudo-bulbs, and not from their apex, as is the case with all others. On one spike were nearly 100 flowers, each about an inch across, the sepals and petals being lance-shaped, of an apple-green tint, and blotched with chocolate; the lip is three-lobed, and of a creamy-yellow tint, the central divisions being elegantly fringed; the apex of the white column and the crest of the lip is of a bright lilac-purple, a colour which gives a bright and delicate aspect to its blossoms. Mr. B. S. Williams staged a small plant of *Cypripedium villosum*, bearing five brown varnished flowers; and a well-bloomed example of the Trumpet-lipped *Dendrobe* (D. lituiflorum), which somewhat resembles D. nobile, but is more slender in habit. The flowers are about 3 inches across, the sepals and petals being white at the base, suffused with bluish-lilac or purple at the tips; the lip is white, shaded with purple, and has a rich purple velvety blotch in the throat. The same collection also included a vigorous plant of *Cymbidium eburneum*, on which there were five flowers; *Aërides Fieldingii*, bearing a small branched spike; and plants of *Trichopilia suavis*, *Lycaste Skinneri*, and the elegant crispy white-flowered yellow-lipped *Dendrobium thrysiflorum*.

Roses.—Mr. W. Paul exhibited three plants of the new Hybrid Perpetual Rose Star of Waltham, which promises to be a favourite. Its colour is rosy-carmine, shaded with purple, the petals being smooth, and of good substance. It obtained a botanical certificate. Mr. H. Bennett, Stapleford, sent a new Tea Rose, named Marie Guillot, a kind having glossy foliage, and creamy-white flowers; and a new Hybrid Perpetual, named Comtesse de Serenyi, in the way of Baroness Rothschild but not so good. Messrs. G. Paul & Son, of Cheshunt, sent a very effective group of Roses in pots, profusely flowered. The blooms on these plants were well-formed, and, as usual, attracted much attention. A new Tea Rose, named Mlle. Marie Finger, was shown in this collection; and Mr. W. Woodley, of Oakwood Lodge, sent a box of cut blooms of *Maréchal Niel*.

Useful Water Barrels.—Where much watering has to be done, a light handy barrel mounted on wheels will be found very useful. One of the best and cheapest appliances of the kind that I have seen of late years was introduced by Messrs. Boulton & Co., of Norwich, some ten or eleven years ago. The barrels had been used for importing and storing paraffin oil, and though by no means heavy were very strong, and were mounted on light iron carriages. We have two of them that have been in regular use in summer for ten years, and are now in good sound condition.—E. HOBDAK.

Plant Labels.—I cannot quite agree with your contributor's article (see p. 253) on this subject. I have long advocated the manufacture of a white delf or porcelain label, with black letters burnt in. Such a label could be made at a small cost, and would, I feel sure, command universal adoption, from its legibility and superiority to anything of the kind extant.—WINCHMORE. [We should ourselves adopt no label which is not capable of being used for other plants besides the one for which it was first written, as the plants in a garden undergo frequent change; and we have always observed that in the case of labels such as those of which our correspondent speaks, there is much waste.]

Generation and Explosion of Gas under a Saddle Boiler.—A nurseryman who is a neighbour of mine, and who has had all his houses heated with hot water by a local firm of ironmongers, is sadly troubled and annoyed by the generation and explosion of gas after his stoker has banked the fire up for the night and shut the furnace and ash-pit doors. These doors open or shut with a lateral motion, and therefore cannot be blown out very easily, but the soot-doors are, on most nights, blown out, and this with such force as to be sent two yards across the stoke-hole. Can anyone suggest a remedy? The stoker has tried various ways of arranging the fire, but, as yet, he has not been able to hit upon the right one.—N. H. P.

OBITUARY.

WE have to record with much regret the death of Mr. Daniel Hanbury, which took place on the 24th ult., at the comparatively early age of 49. As a scientific writer he has been known for upwards of twenty years; but he will be best remembered by the latest of his literary works, the "Pharmacographia," which was the joint production of himself and Professor Flückiger. The value of this work, a review of which appeared a short time back in these columns, is already widely recognised, and will always remain an honourable record of the persevering patience and knowledge of its authors. In horticulture, Mr. Hanbury took much interest. He was better acquainted with medicinal and officinal plants than any other botanist with whose writings we are acquainted, and cultivated many of the rarer kinds.

NOTES AND QUESTIONS—VARIOUS.

The Japan Oak Fruiting.—I have a plant of Japan Oak (*Quercus glabra*) which has at this time a considerable number of very small Acorns on it growing in spikes. I am not sure whether this occurrence is sufficiently rare to be worth mentioning in THE GARDEN, but shall be very glad to learn from any of your correspondents if it is at all uncommon.—K.

Yew Poisoning.—We have had many deaths here from Yew poisoning, but only in the winter, when the sap is down. I have known live Yew to be eaten during summer without any ill effects, while dead Yew is certain death. Laurel will kill during summer and winter, but both in the case of this and Yew dead or decayed leaves are most to be guarded against.—A. MACFARLANE, Great Tew, Enstone.

Telegraph Cucumber.—For six years past I have grown many kinds of Cucumber for winter work, but last season determined to grow none but Telegraph, and right well they have served me. I am no advocate for freezing my Cucumbers at night and broiling them during the day, but keep the temperature at from 65° to 70° at night just now, with an increase of 10° during the day.—R. GILBERT, Burghley.

Lateness of the Season.—According to present appearances, there will be little need of fruit tree protection this year. On Tweedside, few Apricots are in flower, while last year they were in full bloom, and in some places past; of Pears, scarcely one is expanded, and even the common *Ribes sanguineum*—to show the backwardness of blossom—is not in flower, or near it. Horse Chestnuts are still motionless, and their young buds show as yet no symptoms of growth.—CHEVALIER.

Fine Specimens of *Lilium giganteum*.—With reference to "G. K.'s" note in last week's GARDEN on this subject, I may point out that Professor Owen's plants are grown in the open garden throughout the year—a very different thing to growing them in pots. It is not uncommon to see this Lily grown to a large size in pots. It is however, better to grow it in the open air where this can be well done, and the effect of the stately Lily among the round-headed Rhododendrons and other shrubs is very striking.—R.

How to Grow Spinach.—If you want a profitable crop of Spinach, give the leaves plenty of room for full development. A distance of 12 inches from plant to plant is not at all too much, and Winter Spinach should have about 18 inches. The quality of the crop under this treatment will surprise those who grow it thickly. In sowing, use very little seed, and when the crop is well up thin out with a hoe, so as to leave the plants from 6 to 9 inches apart, and then use every alternate plant when large enough, cutting only the largest leaves of the permanent plants when ready.—R. P. B.

Top-dressing Rose Beds.—Beds of Roses on their own roots are often in this season dug over after pruning. The better plan is to surface the bed with almost any kind of soil than to do this. Even a heavy clayey soil, which in one place would be useless, when put on the surface of Rose beds is of great value. In fact, I prefer a mulching of soil to a mulching of dung. After the soil is put on and allowed to lie for a time, it can be raked over, the rough lumps broken, stones picked out, and otherwise left smooth. The shoots may then be pegged down.—CHEVALIER.

Spanish Chestnut.—At page 265 it is stated that the Spanish Chestnut does not ripen its nuts north of the Thames. This is barely correct, for in warm seasons I have eaten the kernels of it in Dumfriesshire and also in Yorkshire; they were not large, however, but apparently ripe enough. The tree grows well here in our thin soil, about the coal measures. In fact, the soil is not above a foot deep, the bottom being a loose kind of rag-stone of a yellowish iron character, among which the roots of the trees penetrate. No other tree grows so fast with us.—J. S. W., Sheffield.

Bitterness in Cucumbers.—In addition to the causes assigned for this by your correspondent "B." (see p. 263) may be mentioned dryness at the root, which, of course, would cause slowness of growth. It doubtless often happens that the bottom of the bed in which Cucumbers are growing in houses (they are seldom bitter on dung-beds) is quite dry, whilst the top is moist or even wet; and in such cases I should expect the fruit to be bitter, even if nothing worse was the result. But bitterness arising from this cause may always be removed in twenty-four hours by thoroughly saturating the rubble, in which the pipes are laid, with water.—E. HOBDAK.

Loose Hay as a Protector.—Mr. Wildsmith advises (p. 269) his readers to shake hay over dwarf bushes and pyramids of hardy fruit, in order to protect them. Does he mean that it should be thrown broadcast over the trees? I can understand twisting hay into ropes, and winding them round, upwards and downwards, and in and out, among the branches; but if he shakes hay loosely over the trees, he must be living in a very sheltered spot, or the cleanliness of his grounds must be a secondary consideration with him. A large farmer once consulted me as to altering the site of his garden, which was close to his stack-yard; and it was always strewn with bits of hay and straw. I pointed out the protective nature of the stack-yard, but order and neatness were to him of more importance than a slight protection.—CHEVALIER.

Hardiness of Sweet Peas.—Your correspondent, Mr. Muir, in his article on Sweet Peas (see p. 255) seems to have ignored the fact, which appears not generally known, that the Sweet Pea is perfectly hardy, and if sown in October, November, and December may be had in bloom a fortnight or three weeks earlier than when sown in April, and, if I mistake not, the early blooms used for bouquets in Covent Garden are obtained in this manner. If sown in February they will bloom earlier than when sown in April. I have some now earthed and staked which were sown in an exposed place in December; the early-sown plants are more vigorous than those put in later, and this applies generally to the annual species of the hardy Leguminosæ. It will hardly, therefore, be an advantage to sow in pots or under glass to gain time.—P.

***Dracæna australis* in the West of England.**—Fourteen or fifteen years ago, I had seed of this plant sent from New Zealand, under the name of the Cabbage Tree of that country, from which I raised a large batch of plants; some of which were planted in the open air, in good well-drained soil. They grew remarkably well, soon formed handsome specimens, and were quite unprotected and uninjured throughout the winter, until the severe weather in 1866, when they were killed to the ground. In the following spring they threw up suckers, and from that time have been quite uninjured. One plant I have just measured, which threw up two suckers, each 11 feet high, has clear stems of 4 feet, the leaves drooping to within 18 inches of the ground. Another is 8 feet high, with a single stem and leaves to the ground: it is not so high, having been transplanted. There are several others of various heights, but all are handsome specimens, and give the place a very tropical appearance. I have raised plants from seed produced in the open air, grown by Mr. Culley, then gardener to W. W. Buller, Esq., Strete Raleigh. The young plants, when first planted out, require protection from rabbits and hares.—JOHN GARLAND, Killaton, Exeter.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE BEST METHODS OF TRAINING FRUIT TREES.

It is exceedingly important that training should be thoroughly understood by every one who has to deal with fruit tree culture, or serious disappointment will almost sure to be the result; for the same method of training is not adapted to all kinds of trees nor to all situations, and timely thought on these matters would always be advantageous. When trained on walls, or as espaliers, the horizontal or the fan systems are most generally practised in the case of Apples and Pears on the natural stock; and, as there are few situations in which either the one plan or the other may not be adopted with success, let us first speak of these two systems. There are modifications of the fan, but the ordinary "spread fan" is the simplest, and it embraces all the advantages of the others, of which it is unnecessary to speak. The primary object of the fan shape is to secure an equal distribution of the sap throughout the whole tree, while directing it into as many channels as possible at the outset, in order to cover the wall quickly, and at the same time expend the vigour of the tree in as many outlets as possible—the first step towards fruitfulness. In originating a fan-shaped tree the branches should be started at the point nearest the graft. Nothing like a stem should appear, however short, in the centre, but every branch should diverge from the root, at equal distances apart, with rather an open centre in the tree than otherwise while it is young. The training of a fan is very easy, and consists in simply carrying the points of the main limbs forward as fast as they will grow consistently with well-ripened wood, and in originating auxiliary branches from their upper side, as the radius of the tree extends and the spaces widen between the branches. The fan system should never be adopted on low walls, with trees on the natural stock, as the central branches reach the top of the wall in a few years, and can then only be kept within bounds by a constant system of mutilation, fruitfulness being out of the question. There are some good fan-trained Jargonelles here, with bottom branches 30 feet long; but the wall being only 12 feet high, the middle branches are thick, and make nothing but gross wood annually. Had the trees had room, some of them would have covered 500 yards superficial area, if not more, and by this time such a tree might bear sufficient fruit to fill an ordinary-sized fruit room. It is simply astonishing how much surface a vigorous-growing fruit tree will cover in time, or even in a few years, on the extension system. At Thoresby Park are to be seen wall trees of large size and in excellent bearing condition, that were planted only ten or twelve years ago by the present superintendent, Mr. Henderson. Nothing covers walls of high buildings so fast, nor with such good results, as some of the strong-growing Apples and Pears. If the trees can have a vertical extension of 50 feet or more all the better. At Cannon Hall, in Yorkshire, there are, or were, some fine Pear trees to be seen trained against lofty walls of some of the offices near the gardens, which bore great crops of excellent fruit every year. In such a position a Jargonelle or Marie Louise, for instance, would be at home under a free system of training and extension. For espalier or wall trees of moderate height, the horizontal system of training is undoubtedly the best to adopt in the case of all strong-growing varieties. The simplest method—the training up one straight stem, from which the horizontal branches are all originated about 9 inches apart, and trained at right angles to it, is that here alluded to. By no other system of training can the sap and vigour of the tree be so equally distributed; consequently, while on fan or oblique-trained trees the fruit is often borne in greatest quantity at the extremities of the branches, leaving the heart of the tree unfertile and bare, on the horizontal it is evenly distributed over the whole surface of the tree. This is a well-marked and constant result of the system, and is exhibited to perfection in the little cordon, which is simply a horizontally-trained tree, with one or two limbs instead of fifty. In training young

horizontal trees, it is only necessary to preserve a central shoot, which must be cut back every winter to the bud next to, and above, the two which are to form the horizontal branches the following season, the top bud being the leader, which must be stopped at the height of 18 inches or 2 feet, and the two horizontal shoots allowed to grow as much as they will. Care must be taken also that the latter do not dip, but rather ascend a few inches, at their point of origin. The oblique system of training is generally adopted in the case of weak-growing varieties, the side branches, as the name indicates, being all trained in a slanting, upward direction from the central trunk, instead of at right angles to it, otherwise this mode of training differs in no way from that of the horizontal. The slightly upward direction of the branches is favourable to the flow of the sap. Of the curvilinear, upright, wavy systems, &c., nothing need be said, as they possess no advantages over those described, while they are more fanciful, without being more ornamental, and are often much more difficult to carry out. The fan system of training is undoubtedly the best for stone fruits. Unlike the Apple and Pear, these often make gross shoots in an irregular manner, and, as in the case of the Apricot and Plum particularly, the branches often die off here and there, leaving blanks that could not be filled up successfully by any other system of training than the fan, which permits of a re-arrangement of the branches. Besides, anything approaching the horizontal method renders the branches more liable to die off, and encourages a disposition to make gross shoots, which are the forerunners of "gumming," and often make stone-fruit culture a difficulty in some situations, unless the trees are in experienced hands. Still, though it is pretty well known that horizontal training is altogether inimical to the well-being of stone fruits, it is a method not unfrequently adopted; but a good example of it is seldom met with. On the contrary, one of the worst specimens of Peach-tree training perhaps ever seen was the result of an attempt of this kind. The trees were bare of wood at the bottom, though rampant at the top; and, though strong watery shoots could occasionally be originated lower down from the main trunk, no sooner were they bent down to the horizontal position, than their vigour seemed to be gone; for the following year, if they did not die, they remained stationary, originating a fresh shoot near the base, perhaps, which grew well enough while it was allowed to grow upright, but went the way of the others when bent down in its turn. The trees had to be headed down eventually, and trained on the fan system, than which no other should be recommended. Consequently, stone fruits should never be planted against low walls, unless time can be afforded to pinch and root-prune in a systematic manner, for, when there is room for extension, root-pruning is not often required. Fan and espalier trees are generally planted about 40 feet asunder, and between them are placed "riders" or standards, with 6 feet stems, as extras, to cover the top part of the wall until the dwarfs grow up. Before leaving the subject of wall and espalier training, let us just refer to the more modern plan of furnishing walls with cordons, on the upright or oblique system of training. Undoubtedly this is a first-rate plan of covering low walls with trees on the Quince or Paradise stocks. In some cases a wall 12 feet high may be covered completely in three or four years, by planting the trees 1 foot apart, and taking up one stem from each. Of course a continuous and persistent system of summer-pinchings of the side-shoots is the great desideratum with trees of this description. No systems of training trees in the open ground—round a kitchen garden, for instance—are more conducive to fruitfulness, or more ornamental, than those indicated above. We have had experience of other systems, and notably of the pendulous or balloon plan of training Pears and Apples, but it has not been favourable, if results are to be estimated by the returns given for much labour and pains—in the first instance to make the trees, and afterwards to keep them in shape; for, while they bear no better than bush trees, and not nearly so well as espaliers, generally speaking they want much tying and training and close attention to the rubbing off of the buds at the top of the trees at an early stage, as these persist in pushing with great vigour, to the detriment of the lower branches. Neither can such trees, which eventually assume a rude table shape when the limbs get thick and old, be con-

sidered ornamental in appearance compared with an easy and naturally trained pyramid or well-shaped bush tree growing as Nature intended it. In fact, the "balloon," the "vase," and other rigid forms of training, belong to the age of clipped Hollies and other shrubs, when no tree was considered beautiful that had not been tortured into fanciful shapes according to the taste of the operator. A properly trained bush tree may be made to look symmetrical without being rigid or formal, and by keeping the centre of the tree open, like a Gooseberry bush, and pinching the side shoots of the main limbs once or twice during the summer, as fertile a fruit tree may be created as could be by the most elaborate system of training. Bush trees in some gardens are grown in the form of a round ball, the centre of the tree being filled with wood; this, however, is a wrong practice. They should be trained in the form of a cup, with sloping sides, so as to present as great a surface to the sun and air as possible, and in order that the branches may bear equally on both sides—i.e., inside and outside the cup. A tree of this kind can be formed easily, without the use of a single stake or tie, by simply attending to the practice of always cutting back to an outside bud when shortening the leading shoots. The young tree should at the outset be cut over about 9 inches from the ground. It will push perhaps from four to six shoots the following year. Those which point outwards should be pruned to an out-pointing bud, and the most central shoots removed. The third year the divergence of the branches will be still greater, and the same tactics must be pursued, and so on annually till size and form are secured, which cannot be expected till the branches become somewhat numerous. Apples and Pears of a spreading habit assume the cup form most readily, but the most upright-growing kinds conform easily to systematic pruning, and in the end make the most symmetrical specimens. A somewhat aged Apple tree, scarcely a hundred yards off, which has been operated upon in this way for years, is now almost as perfectly circular in shape, and as evenly balanced as if it had been trained by rod and line, while the limbs are well-furnished with bearing spurs to the ground. Of pyramidal training it need only be said that it is one of the most elegant, easy, and best methods that can be adopted, especially in small gardens, where space is an object.

J. S. W.

RETARDING FRUIT BLOSSOMS ON WALL TREES.

IF the unusual lateness of the season has been trying to spring gardeners, it has been pleasing to fruit growers, for it is a sure fore-runner of a full crop. The greatest difficulty or danger with fruit trees in the spring arises from their precocious excitability. The early bright hot days that awaken the Violets from their winter's sleep in shady places, and quicken the Primroses into beauty on their warm hedge-banks, likewise arouse the dormant buds of our fruit trees into activity, at the risk of almost certain destruction. The buds of all fruit trees are exceptionally late this season, and therefore tolerably safe, and as this is universally admitted, it is somewhat surprising that so little is generally done to retard the blossoming of fruit trees on walls. Various expedients might be adopted for this purpose, the most obvious of which are to shade the trees from early sunshine, to move them off the wall during the winter and spring months, and to change the aspect in the case of some of our more excitable fruits. The question of shade is a somewhat difficult one, and has been brought into disrepute through a reckless and thoughtless use of it; for instance, where canvas rollers are used tolerably close to the wall, they are often let down during bright days, and no doubt shut out the direct light of the sun; but, on the other hand, they allow his heat to pour through them into the small space between the canvas and the wall, whence there is no outlet for the heated air. Without ventilation at the top, such modes of shading are useless, and are even worse than if the blinds had been left up. The increase of temperature and close atmosphere draw out and induce the buds to expand with unusual rapidity, and add to their tenderness and delicacy. If any sort of textile fabric is used for shading, there should be a free space left between its upper edge and the face of the wall. By such a disposition of the shading material, the direct rays of the sun are not only kept off the blossoms, but a current of air is established. Next to opaque screens, woollen netting, &c., perhaps the most useful kind of shading for fruit trees on or off walls are boughs of Spruce, Yew, or branches of Laurel, and other shrubs. If properly arranged they shut out the sun by day, and help to keep off frost at night. They cause innumer-

able eddying currents of air in the immediate vicinity of the blossoms, tending to the modification alike of the heat of the warmest day and the cold of the coldest night. These primitive shades may also be said to be self-adjusting. They gradually become defoliated, and so get thinner, and by the time they are least wanted, they have become mere skeletons, and may be removed, without risk or injury to the blossoms they have sheltered or shaded. Rough straw bands, mounted on poles a foot or two from the walls are also among the most efficient of all available means for the shade and protection of fruit trees. The loose straws, in motion or at rest, cut asunder, as it were, the direct rays of the sun, and likewise tend to impede the energy of radiation. The removal of fruit trees off the walls in winter is a sure mode of retarding their blossoming. Trees thus treated also enjoy a much more uniform temperature than those left upon the walls. In fact, a south wall, while furnishing, upon the whole, the highest temperature available in our climate, also exposes trees to extreme variations. It is the latter, rather than any absolute degree of cold, that creates most damage among fruit trees. The sudden alternations of heat and cold so unsettle the blossoms that they are often ready to drop off, or be destroyed by the merest breath of cold that would not have injured them in the least had it found them in sound condition. Unfastening trained trees annually will be condemned by many as troublesome and impracticable. No doubt it would involve much labour; and where the latter is scarce, as it is in most gardens, the practice may not be possible. Nevertheless it would save many a crop, and would also, in many cases, add to the strength and improve the health of the trees, while the bare walls could be readily cleansed from the larvæ of insects that too often find a congenial and a safe home behind the branches, in old shreds and in ties. But why should Peaches, Nectarines, and Apricots, always have a south or even a west wall? In many parts of England these fruits would perhaps ripen perfectly on a north-west or east aspect. One of the most fruitful Apricots I ever saw was on an east aspect. Perhaps your correspondents will kindly give their experience in this matter, as it is one that needs ventilation. In the eastern counties, for instance, we often find the hotter the aspect the shorter lived are the wall trees. Peaches and Apricots stand longer on west than on south walls; Apricots will ripen on east walls. Has anyone tried them on a north wall, and with what results? I have found the Golden Drop Plum, on an average of seasons, fruit more plentifully on a north-east or north-west than on a south wall. The chief reason seemed to be that the blooms were a fortnight or three weeks later, and consequently a crop became more certain. Singularly enough the fruit least exposed to the sun had at times the most flavour. I have observed the same in regard to Peaches and Apricots. Apricots, on the whole, may be higher flavoured on a west than on a south wall. That the sun may burn the flavour out of fruit is pretty generally acknowledged by practical men. Be that as it may, however, the retarding of the blossom of fruit trees by a change of aspect is one of those questions that might be profitably discussed at the present time, when an unusually late season shows us the importance of the late-blooming of fruit-trees as regards a plentiful fruit harvest.

D. T. FISH.

SHADING PINE-APPLE PLANTS.

I OBSERVE that in your "Calendar" the old-fashioned system of shading Pine plants is recommended, and that too as early as the first week in April. This plan of growing the Pine-apple dates from the last century, when it was considered as an annual-rooted plant which required to be dis-rooted every spring, and started afresh. At that time, nothing was known of the various modern methods of heating, and there was some excuse for the use of shading; but in these days, when Pine-growers have every convenience of this description, and are familiar with the application of artificial heat and the means of regulating the temperature and humidity of the atmosphere of their Pine stoves, one may be forgiven for wondering why a practice, which was once considered obsolete, should again be revived. The advice that the roof-sashes of Pine stoves should be painted with milk and lime will be considered by a large number of Pine-growers as wholly unsound. It will appear to them quite as unnecessary to shade Pine plants as it is to shade early Vineries, Peach, Fig, Cherry, Plum, or other fruit houses. In such a climate as that of England, it is no wonder, when such a practice obtains, that there are so many badly swelled and imperfectly coloured fruit, and that so many complaints of "black-hearted" Pine-apples, and watery insipid Melons, &c., should be made. No wonder either that your contributor should some time back have condemned that splendid variety, the Queen, on account of its taking such a long time to furnish a fruiting plant. He spoke of two, three, or even four years being required to accomplish this; for my own part, I never knew any kind of Pine-apple that

gets sooner into a fruiting condition than the Queen, a variety of which I have fruited many thousands, from eight to fifteen or sixteen months old, and the fruits thus obtained were perfect, both in point of size and beauty. An experience in Pine growing which extends over fifty years, enables me to assert that Pines produced by old plants never were, and never can be, as fine and perfect as those cut from sturdy, robust plants of a few months' growth, pushed on without check and without that period of rest that is so strongly, but I think so unadvisedly, recommended by some Pine growers. My system is to grow them on continuously until they have fruited; and, although it may be true that a Pine plant may, by shading, and by the administration of poor, insufficient nourishment, be kept growing on, without showing fruit, the latter, when it does appear, will invariably be of a comparatively inferior quality. The complaint of your contributor, that his Queens took a long time to fruit, may be a perfectly true and just one, but the circumstance requires no further explanation than the candid admission which he makes respecting the treatment to which they were subjected. J. BARNES.

Fruit Prospects in Yorkshire.—Fruit prospects generally are good. Apples, Pears, and Plums are well set with fruit buds. Many Apricots are grown in the north of Yorkshire, and the trees are now loaded with bloom. Peaches and Nectarines are promising, but are not grown in large quantities hereabouts, on account of the uncertainty of the crop ripening in unfavourable seasons. The Gooseberry crop is not very promising, on account of the great destruction of buds committed by birds during the late severe winter. Long shoots of last year's growth, 18 inches long, may be seen with every bud stripped off, except two or three at the end of each shoot. They are now coming into bloom, and appear to be a fortnight later than usual. Raspberry canes, owing to the dry summer last year, are small. Should there be no severe May frosts, we may look forward, in the north of Yorkshire at least, to an abundant fruit crop. This account applies also to the great fruit-growing district of Thirsk.—H. T., *Fencote*.

American Cranberries.—I happened to receive from my valued friend Mr. Gloede, the celebrated Strawberry grower, several numbers of THE GARDEN, and in one of them (p. 232) a correspondent, Mr. E. W. Cooke, asks for hints as to the culture of the American Cranberry. About this part of the subject I know nothing, but I can inform him, I believe, as to the right time to gather the fruit. In the moors and marshes of the Russian province of Kiew the European Cranberry (*Vaccinium*) is very much grown, and the berries are brought to market in large quantities, but not until they have been subjected to a hard frost; for, without this, the jam which is made from them never has the agreeable flavour that makes it such a favourite in some countries. So far as harvesting the fruit goes, there most likely is no difference between the European and the American variety. The jam made from the fruit of the former has an unusually delicate flavour.—EDMUND NIBELSIECK, *Villa Albertina, Hamburg*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Apricot Branches Dying Off (see p. 278).—By raising seedling Apricots, and planting them instead of worked plants, your correspondent will find branches dying off to greatly diminish. This hint I got some years ago from Mr. Powell, of the Royal Gardens, Frogmore, whose skill in all matters relating to fruit culture is well known.—R. GILBERT, *Burghley*.

Grapes well Kept in Bottles of Water.—As I find considerable prejudice is still entertained against the cutting of Grapes, when thoroughly ripe, and preserving them in bottles of water, I send for your inspection a bunch of Lady Downes, cut six months from the Vine, and preserved in bottles of water, as was described by me in THE GARDEN (see Vol. I., p. 348). The Grape-room here is also used for storing our finest varieties of Pears and Apples for dessert.—RICHARD NISBET, *Aswarby Park Gardens*.—[The berries looked as if they had just been gathered from the Vine, and were perfect in flavour.]

Fruit Prospects in Northamptonshire.—Apricots with me on 700 feet of south walling promise to be a good crop; for the last fortnight the blossoms have been most attractive, and just now (April 4th) they are to all appearance setting well. Peaches and Nectarines on south walls are one sheet of bloom. Cherries and Plums on both east and west walls are thickly set with fruit buds, which are swelling rapidly. Pears are also full of fruit buds, more particularly Passe Colmar and Fondante d'Antoine. Apples I have never seen more promising. Fruit trees this season have been at least three weeks later in coming into bloom than usual.—R. GILBERT, *Burghley*.

Loose Hay as a Protector.—In answer to "Chevalier" (p. 292), allow me to say that, unfortunately for my own comfort, I am so constituted as to consider no labour too great if by it my end can be gained, and having more than once saved my Gooseberries from destruction by frost by shaking loose hay over the bushes, I have considered the accomplishment of this worthy of the time requisite to put the place in proper trim again. I did not for a moment think that anyone would take it for granted that I recommended loose hay as a permanent covering; on the contrary, it is only to be adapted on an emergency. Generally the keenest frosts occur on the calmest nights, when but little litter need be feared from the hay, and if there should be, what then? Is not a crop of fruit of more value than a few days untidiness? Let me have the fruit first and the neatness afterwards.—W. WILDSMITH, *Heckfield*.

THE INDOOR GARDEN.

PITCHER PLANTS AT DRUMLANRIG.

WHEN I wrote (see p. 233), asking for a little further information respecting these, I did not for a moment doubt the accuracy of the description given; but I was under the impression that there had been a mistake as to the variety named that had produced the large pitchers in question. It appears, however, that such is not the case. I can assure "F. W. B." that, in objecting to baskets for growing Pitcher plants in, I was perfectly aware of what I was about, having given them a fair trial. No matter how much Sphagnum you clothe the basket with, the roots will protrude through it—and perish, too, unless the atmosphere of the house is kept like a vapour-bath, and too moist for most other plants. The nurserymen who grow *Nepenthes* in baskets simply do so because they have a neater appearance than when in pots, and consequently sell better. When Pitcher plants are produced in baskets half as fine as those which have been repeatedly seen in pots, I shall feel better satisfied with basket culture. Pitcher plants being amongst the most singular of vegetable forms, I should like to see them everywhere where means exist for their culture. They will succeed perfectly in an ordinary stove, where the night temperature in winter is not allowed to fall below 60° or 65°. They like to be hung up close to the glass, and moderately, but not too heavily, shaded from the sun, from the middle of March to the end of September. They cannot endure their roots in soil of a close adhesive character, or at all sour or retentive of stagnant moisture. The quantity of water which they must have, especially while growing, makes it necessary to be particularly careful to guard against such conditions; therefore, nothing but fibre from the best peat, with nearly all the earthy matter removed from it, should be used. This, cut or pulled into pieces about the size of pigeons' eggs, with about an equal quantity of chopped clean Sphagnum, and one-fifth of charcoal or broken crocks, are what I have always used. I fill the pots one-fourth with drainage, over which I place a little Sphagnum. In re-potting, I do not even move the crocks from the bottom, if the roots are matted amongst them, for they are the most brittle, as well as impatient of injury, of any roots with which I am acquainted; so fragile are they, indeed, that I have known persons, in potting these plants, pull the roots off, under the impression that they are dead. They dislike over-potting; a 6-inch pot is large enough for a plant of *N. Rafflesiana*, with a single shoot until it gets 3 feet high, when it may be shifted into one a couple of inches larger. The soil must never, even when the plants are at rest, be allowed in the smallest degree to approach a dry condition; water thoroughly twice or three times a week in winter, and every day when they are growing. Syringe overhead every day, as they are liable to thrips, which, if allowed to remain on them, will destroy the Pitchers long before they arrive at perfection. By following diligently these details, anyone may grow Pitcher plants. In conclusion, I would say, especially to those who have not had experience in their cultivation, grow them in pots; and, if there is any objection to the appearance of the latter, plunge them in baskets lined with living Sphagnum. T. BAINES.

Top-dressing Azaleas and Camellias.—Mr. Muir's further explanation of his views on this subject (see p. 276) only makes the practice which he advocates appear more palpably bad. Injurious as it is to a plant to destroy its roots in moving the existing surface-soil to make way for new material, it is infinitely worse to lay the new soil on without removing any to make room for it. More of the least easily managed hard-wooded plants are killed in potting through not keeping the collar of the plant and the thick roots at their junction with it sufficiently elevated and in a measure above the soil than through any other cause. If ever we see a hard-wooded plant continue in health and vigour to an age beyond the generality of its species, it is sure to be one that has the collar and principal roots, where they proceed from it, almost above the surface; for to cover these with fresh soil would simply be to ensure destruction. All seeds of trees and shrubs are naturally self-sown on the surface; having vegetated, the young plants are invariably found with the collar and some portion of the roots more or less above ground. Deep planting, or, what is the same thing, adding soil to the surface at any time after planting are alike injurious in their effects. Some plants are enabled through the strength and vigour of their constitution to bear up under unnatural treatment, but delicate-rooted hard-wooded subjects usually die. Let us, therefore, endeavour, if possible to obviate such a result.—T. B.

Begonia erecta multiflora.—This makes a pretty and useful decorative plant, having metallic-coloured leaves and pale pink flowers, which are produced in great profusion at every leaflet. In large 60-sized pots placed along the curbs of the plant-stove, it contrasts well with other plants, either in or out of bloom, and ought to find a place in every collection.—R. GREENFIELD.

NOTES OF THE WEEK.

— TWELVE years ago few gardens contained any Lilies at all, beyond perhaps a few of the Japan kinds in pots, all the other hardy kinds having been discarded; since then they have, fortunately for our gardens, become remarkably popular. The number of fine species is multiplying so rapidly in our gardens, and so many desire to have them correctly named, that we have thought it well to translate Mr. Baker's exhaustive account of the species (originally published in Latin in the "Linnean Society's Journal"). For various reasons it has been considered best to publish the description of all the species in one number, and we have attempted to illustrate, as well as possible under the circumstances, all the kinds of which figures are obtainable. It may be as well to add that Mr. Baker is not responsible for the selection of these illustrations, or for the appearance of the article in its present form. Upwards of twenty of the best illustrations are from the pencil of Mr. Burbidge, engraved by Mr. Hyde.

— In the Edinburgh Botanic Garden, Mr. M'Nab states that, in spite of the severity of the winter, comparatively little injury has been done to vegetation. He adds that the small number of plants in flower on the 1st of January is in marked contrast to that of the same day last year. In 1875, the only blossoms obtainable were *Jasminum nudiflorum*, four species of *Helleborus* or Christmas Rose, and *Gentiana acaulis*; whilst, in 1874, no fewer than 138 species and varieties were collected in flower. Dr. Moore writes to us from Glasgow, and says that it is the latest spring they have experienced at Dublin for many years.

— WE have received a canister of Oyster Bay Asparagus which is said to be better than French preserved Asparagus. Oyster Bay township on Long Island is the place where it was grown and preserved. It is a specimen of very good Asparagus cut at its best, and therefore delicate in texture, and of a good green colour. We confess, however, that like all preserved Asparagus, it tastes somewhat of the can. This, however, may be an insurmountable difficulty in the preservation of Asparagus, for nothing could be more carefully preserved than this appeared to be.

— WE are requested to state that the Pelargonium trial at Chiswick will be carried out as usual; and that the officers of the Royal Horticultural Society, desirous of keeping up to the utmost the status of the Chiswick Garden in the present precarious state of the Society's affairs, will this season make a special effort in this direction. They, therefore, trust that the raisers of seedlings, as well as the introducers of foreign novelties, will, as usual, send for this purpose plants of such new varieties as they may be able to spare; and if they will, at the same time, specify whether or not they would desire any of them to be grown in pots, Mr. Barron, the superintendent, will be ready to give effect to their wishes. The superintendent is prepared to receive and take charge of the plants at once, and requests that those who intend to send will do so as early as possible, addressed to him, at the Royal Horticultural Gardens, Chiswick.

— A CONFERENCE consisting of delegates from the Agricultural, Botanic, Royal Dublin, Horticultural, and Meteorological Societies, has, at the request of the last-mentioned, drawn up some "Instructions" for the observation of the appearance of certain plants, insects, and birds. In the preparation of these instructions the conference was greatly assisted by the Rev. T. A. Preston, of Marlborough College, who has worked for many years laboriously at such records. A list of seventy-one of the most widely-distributed and commonest plants is given, and those who cannot undertake to observe so many are requested to pay attention to fourteen of them printed in capitals. This is followed by some necessary instructions, and a table of average dates for ten years, as observed at Marlborough, of the appearance of the various species. So far as appears, it is only the observation of the date of first flowering that is required. Forms for such records may be obtained at the Meteorological Society's offices, 30, Great George Street, Westminster.

— SOME time since a suggestion was made that the Pelargonium Society should hold its show in the great conservatory at Chiswick, instead of at South Kensington, and the proposal seemed so apposite, that many of the members felt inclined to adopt it. On more mature consideration, however, it was found that the competition for Messrs. Veitch's fruit prizes was fixed for the same day. As these two items, fruit and Pelargoniums, made up last year one of the best South Kensington shows of the season, and as Messrs. Veitch objected to the competition for their prizes taking place at Chiswick, the committee felt that any change of the original arrangements would do an injury to the Royal Horticultural Society, without yielding any corresponding benefit to the Pelargonium Society. The show will, therefore, be held this year at South Kensington, as announced in the circulars already issued. The Committee hope, moreover, to be able to make

arrangements to hold the Pelargonium show next year at Chiswick, at a date which, as nearly as possible, may coincide with the height of the blooming season of the bedding varieties, which could scarcely have been the case this year, the date being fixed for July 21.

— THERE is no chance of the contemplated exhibitions of Amsterdam and Brussels interfering with each other. At a meeting of delegates held at Antwerp during the exhibition just closed, it was decided that Brussels will celebrate its centenary next year, and that Amsterdam will hold its great exhibition in 1877.

— BIRDS often destroy the blooms of Crocuses, a fact which may be observed in the case of those in the flower-beds in Hyde Park. It is remarkable, however, that while the yellow flowers are extensively destroyed, the white ones remain uninjured.

— LAST season, General Bidwell, on his estate of 22,000 acres, planted 110,000 Grape Vines of the White Muscat of Alexandria, the great raisin Grape of California. He commenced making raisins of this Grape last autumn, and those he has on hand now are, according to the "Californian Horticulturist," certainly as fine as any Malaga raisins can be.

— A DISEASE, similar to dry rot, is stated to have attacked the Lemon plant. It seizes sometimes the roots, sometimes the branches, whence it gradually spreads through the whole tree, drying up its sap in its course. Attempts have been made to check its ravages, but hitherto without success. It is said that similar appearances have been noticed in Orange plantations.

— WE have recently purchased some preserved Lima Beans in London, and find they retain to a great degree their good and peculiar flavour. This excellent Bean is too tender for open-air cultivation in this country, but it would probably repay those who gave it a chance in a forcing house. It is very popular in warmer countries than ours.

— AN official decree has been published in France, prohibiting the importation into, and the transit through, that country of Potatoes from the United States or Canada. Dead leaves, as well as sacks and barrels, or other articles which have been used for the packing of Potatoes, are included in this prohibition.

— THE well-known Manley Hall estate, near Manchester, including the mansion, the conservatories, Ferneries, and shrubs, and 80 acres of freehold land on which they stand, has been sold by Mr. Sam Mendel to Mr. Ellis Lever, of Spring Bank, Bowdon, who is well-known in Manchester as the principal of the Midland Coal Company. The estate realised, we understand, nearly £150,000.

— THE Enclosure Commissioners have made their annual report of proceedings under the Metropolitan Commons Act of 1866. Since the passing of the Act there have been five schemes certified by the Commissioners and confirmed by Parliament, viz., for Hayes Common, Kent, about 200 acres in extent; Blackheath, 267 acres; Shepherd's Bush Common, 8 acres; Hackney Common, 166 acres; and Tooting Beck Common, 144 acres.

— AMONG beautiful hardy flowers now in bloom in London gardens are the rich blue *Scilla sibirica*, five or six species of Daffodils, the delicate porcelain blue-tinted *Puschkinia scilloides*, and several rosy and white-flowered ornamental-leaved Dog's-tooth Violets. Gold-laced Polyanthuses, and white, purple, lilac, and crimson Primroses are likewise now very attractive, as is also the lovely blue Forget-me-not (*Myosotis dissitiflora*) in sunny corners. Moreover, the rich purple gold-spotted bulbous *Iris reticula* is very effective, as is also the crimson-purple *Sisyrinchium grandiflorum*, a plant possessed of fairy-like grace, and perfectly hardy.

— THERE are some happy spots not visited by such easterly breezes as in Europe and America have of late withered buds and men alike. The "Californian Horticulturist" of March says, the rapid development of the season is now seen in all warm and sheltered districts in this region. In Solano, Suisun, Napa, and Sonoma, since the rains, the grains and Grasses have grown as rapidly as "Jonah's Gourd," and in these regions the Almond and Plum trees are bursting into bloom. Most fortunate has it been for our fruit crop, that we have had cold weather and no rains till recently. Thus far everything bids fair for an immense crop of fruit of all kinds. The supply of Green Peas was never known to be so large as it was about the end of February. A few were generally to be found in market all winter, but they were never before sufficiently abundant in February to sell for 3d. or 4d. per pound. Within two or three years a considerable tract of land along the foot-hills in the vicinity of Warm Springs, Alameda County, has been found peculiarly adapted to the growth of early Peas, in consequence of its almost entire exemption from frost, and this region now furnishes almost the whole supply. The daily receipts average nearly 100 sacks, or about 4 tons. Asparagus came forward at the same time in limited quantities, but the abundance of Peas interfered materially with its sale, and kept articles below the fancy figures usually obtainable at this season.

THE FLOWER GARDEN.

ALL THE LILIES.

Generic Characters.

PLANTS of the temperate zone of both the New and the Old World, with scaly bulbs, numerous leaves, either scattered or in whorls, and with handsome summer-blooming flowers produced in racemes or solitary. Perianth, corolla-like, deciduous, in six divisions, funnel-shaped, with equal ob-lanceolate segments, which are more or less falcate in the expanded flower, smooth, or on the upper surface marked with flat prominences, white, or of a splendid yellow or red colour, never tessellated, the claws furnished with a distinct nectariferous groove, which, however, is sometimes wanting; stamens, six in number, equal in length, faintly perigynous, included; filaments, elongated, thread-like, or slightly flattened, more or less curved; anthers, versatile, attached on the inside by the middle of the back, dehiscing outwardly along the entire margins; ovary, sessile, cylindrical, three-celled; ovules, numerous, horizontally arranged in each cell; style, club-shaped, more or less curved, most frequently longer than the ovary; stigma, rounded, three-lobed; capsule, coriaceous, obovoid, six-angled, with a three-valved loculicidal dehiscence; seeds numerous, discoid, margined, and with a brown membranous skin.

Sub-genus I. Cardiocrinum.—Perianth, funnel-shaped, with oblanceolate segments, falcate only at the apex.

Leaves, stalked, heart-shaped, ovate.—1, cordifolium; 2, giganteum.

Sub-genus II. Eulirion.—Perianth, funnel-shaped, with oblanceolate segments, which are falcate only at the apex; leaves, linear or lanceolate, sessile, or nearly so.

Tube scarcely widened from the base to the middle.—3, philippense; 4, Wallichianum; 5, longiflorum; 6, neilgherrense.

Tube gradually narrowing from the base to the neck; leaves, scattered.—7, japonicum; 8, Krameri; 9, nepalense; 10, candidum; 11, Belladonna.

Leaves in whorls.—12, Washingtonianum.

Sub-genus III. Archelirion.—Perianth, open, funnel-shaped, with deeply-spreading segments, which are broadest below the middle; stamens, diverging from the curved style.

Leaves, sessile.—13, tigrinum; 14, oxypetalum.

Leaves, shortly-stalked.—15, speciosum; 16, auratum.

Sub-genus IV. Isolirion.—Perianth, erect, with segments, which are falcate in the expanded flower, but not revolute; stamens diverging on all sides from the straight style.

Leaves in whorls.—17, philadelphicum; 18, medeoloides.

Leaves, scattered; style longer than the ovary.—20, bulbiferum; 21, croceum; 22, davuricum; 23, elegans; 24, Catesbæi.

Sub-genus V. Martagon.—Perianth, cernuous, with the segments very revolute; stamens diverging on all sides from the curved style.

Leaves in whorls; American species; bulbs, annual, bearing rhizomes.—25, canadense; 26, pardalinum; 27, superbum; 28, Rœzlei; 29, columbianum; 30, Humboldtii.

Old-world species.—31, Martagon; 32, avenaceum; 33, Hansoni.

Leaves, scattered—leaves, lanceolate—many-nerved; perianth, falcate above the middle.—34, monadelphum.

Perianth, revolute to below the middle.—35, polyphyllum; 36, ponticum; 37, carniolicum.

Leaves, narrowly linear, with one or few nerves; segments of the perianth, from six to twelve lines broad in the middle.—38, testaceum; 39, Leichtlinii; 40, pseudo-tigrinum.

Segments of the perianth, from three to six lines broad in the middle.—41, pomponium; 42, chalcedonicum; 43, callosum; 44, tenuifolium.

§ **Cardiocrinum** (Endl.).—Perianth, funnel-shaped, with oblanceolate long-clawed segments, which, in the expanded flower, are falcate only at the apex, and are not papillose on the inner surface, and have a shallow groove on the keel; stamens, slightly curved, and parallel with the style; leaves, heart-shaped-ovate, with a reticulated venation and long stalks. It is distinguished from the other sub-genera by its Smilax-like leaves.

1. L. cordifolium.—Thunb. Linn. Trans. ii., 332; Schult. fil. Syst., vii., 420; Sieb. et Zucc. Flor. Jap. fasc., iii., 33, t. 13, fig. 2 and 14; Kunth, Enum., iv., 268; Miquel Ann. Mus. Lug. Bat., iii., 157; Saussurea cordifolia, Salisb. Linn. Trans., viii., 11; Hemerocallis cordata, Thunb. Fl. Jap., 143; Gaertn. Fruct., ii., 484, t. 179, fig. 5.—The bulb of this plant is, in every respect, like that of *L. giganteum*, but smaller, and with thicker, more wrinkled, and less regular scales; stem, 3 to 4 feet high, naked at the bottom, and with the leaves at first arranged in rosettes, the lowest ones stained with blood-red, the stem-leaves ovate, deeply heart-shaped, and with long stalks;

the raceme, in the specimens which I have seen, is not quite a foot long, contains from four to ten flowers, and, when fully expanded, is from 9 to 14 inches across, the foot-stalks of the flowers being

Heart-shaped leaved Lily (*L. cordifolium*).

2. L. giganteum.—Wallich, Tent. Fl. Nep. 21, t. 12-13 (excl. syn.); Kunth, Enum. iv., 268; Hook. Bot. Mag. t. 4,673; Flore des Serres, t. 771-2; Belg. Hort. iii., t. 21.—*L. cordifolium*, D. Don, Prod. Nep. 52, non Thunb.—Bulb, globose, caespitose, perennial, 3 to 4 inches thick; scales, ovate, somewhat spreading; stem, 6 to 10 feet, high, terete, smooth, green, 1½ to 2 inches thick at the base; radical leaves, green, not tinged with red; stem-leaves, twelve to twenty in number, extending to the base of the stem, scattered, ovate-acute, deeply cordate at the base, of a deep green colour, reticulated-veined, the lower ones 12 to 18 inches in length and breadth; leaf-stalks, erect-patent, channelled, 9 to 12 inches long, the upper ones gradually smaller, and on shorter foot-stalks; raceme, of ten to twelve flowers, and from 1 to 2 feet in length, attaining a foot in width when fully expanded; bracts, boat-shaped, large, ovate, caducous; pedicels, 3 to 12 lines long, at first almost nodding,

Giant Lily (*L. giganteum*).

but ascending when bearing fruit; perianth, funnel-shaped, fragrant, 5 to 6 inches long, white, tinged with purple on the inside, and with green on the outside; tube, gradually widened from the base (where it is 6 or 7 lines in diameter) to the neck (where it is from 18 to 21 lines in diameter); segments, ob-lanceolate, 9 to 12 lines broad at the base of the upper quarter of their length, gradually narrowed towards the base, inner ones broader; stamens, two-thirds the length of the perianth; filaments, flattened downwards, nearly straight, 3 to 3½ inches long; anthers, yellow, 3 to 4 lines long; pollen, yellow; ovary, cylindrical, 1 inch long; style, scarcely curved, one and a half, or nearly twice the length of the ovary; capsule, broadly oblong, 2 or 3 inches long, obtuse-angled, umbilicated at the apex; neck, large, top-shaped. Temperate region of the whole Himalayan chain, from Kumaon and Gurwhal to Khasia and Sikkim, at an altitude of from 5,000 to 10,000 feet. "It flowers in the rainy season, from May to the end of July," Wallich.

§ **Eulirion** (Endl.).—Perianth, funnel-shaped, with long-clawed oblanceolate segments, which are falcate only at the apex, not papillose on the inside, seldom dotted; groove on the keel shallow; stamens, slightly curved, parallel with the style; leaves, linear or lance-shaped, sessile, or nearly so; flowers, fragrant, often white, never brilliant red nor yellow.

3. L. philippense.—Hort. Veitch; Baker, Gard. Chron., 1873, with a plate.—Bulb, ovoid, perennial; stem, 1½ to 2 feet high, one-headed, slender, terete, smooth, green, or spotted with purple; leaves, thirty to forty in number, scattered, patent-falcate, narrowly linear, 3 or 4 inches long, 1½ to 2 inches broad, smooth, three-nerved,

and of a shining green colour; perianth, horizontal, white, slightly tinged with green on the outside near the base, narrowly funnel-shaped, 7 or 8 inches long; tube, $\frac{1}{2}$ inch in diameter near the middle;

Philippine Island Lily (*L. philippense*).

Wallich's Lily (*L. Wallichianum*).

segments, oblanceolate, falcate only at the apex, long-clawed, 15 to 18 lines broad at three-quarters their length from the base, smooth and undotted on the inside; keel, indistinct, green; stamens, a little shorter than the perianth; filaments, greenish, slightly curved, 5 to 5 $\frac{1}{2}$ inches long; anthers, 2 $\frac{1}{2}$ to 3 lines long; pollen, yellow; style, together with the ovary, $\frac{1}{2}$ an inch shorter than the perianth; Philippine Islands; Wallis in hort. Veitch.

4. *L. Wallichianum*.—Schultes fl. Syst. vii., 1689; Kunth, Enum. iv., 267; Wall. Cat. 5,076; Hook., Bot. Mag. t. 4,561; Lindl. et Paxt. Flow. Gard. 1850, 120, with a plate; Lemaire, Jard. Fleur, t. 105, 106; Flore des Serres, t. 612.—*L. Batisua*, Hamilt. M.SS.—*L. japonicum*, D. Don, Prod. Nep. 52, non Thunb.—*L. longiflorum*, Wallich, Tent. Fl. Nep. 40, t. 20, non Thunb.—Bulb, ovoid, 2 to 3 inches long; scales, thick, white, acute, closely imbricated; stem, 4 to 6 feet high, green, straight, terete, horizontal at the base; leaves, fifty to sixty in number, somewhat distant from each other, scattered, ascending, sessile, acuminate, smooth, green, the lower ones 6 to 9 inches long, 3 to 6 lines broad in the middle, three-nerved, the upper ones shorter and broader, often five-nerved; flowers, often solitary, sometimes two or three in number, fragrant, horizontal from the top of the pedicel or slightly ascending; perianth, white, greenish on the outside at the base, 5 or 6 lines in diameter, at 3 inches above the base; 7 to 9 inches long; tube, 3 or 4 lines in diameter at the base; segments, with oblanceolate claws, acute, 1 $\frac{1}{2}$ to 2 inches broad at three-fourths their length from the base; stamens, 2 inches shorter than the perianth; anthers, yellow, 12 to 14 lines long; ovary $\frac{1}{2}$ inch to 2 inches long; style, together with the ovary, as long as the stamens. The sub-temperate region of the Central Himalayas (Kumaon, Nepal, &c.), at an altitude of from 3,000 to 4,000 feet. In Max Leichtlin's garden there is a smaller and more slender form, with about twenty-five leaves, which are distant from each other, the lower ones smaller than the upper ones; anthers, 6 lines long; and another form, which has numerous leaves (200) much more closely set, and a stem 5 feet high.

White Japanese Lily (*L. longiflorum*).

5. *L. longiflorum*.—Thunb. Linn. Trans. ii., 333; Bot. Reg., t. 560; Lodd. Bot. Cab., t. 985; Bury, Hexand., t. 8; Kunth, Enum. iv., 266; Flore des Serres, t. 270; Miquel, Ann. Mus. Lug. Bat. iii., 157.—Bulb, perennial, globose, yellowish, with lance-shaped scales; stem, 1 to 3 feet high, straight, smooth, green, 3 or 4 lines in

diameter; leaves, twenty to forty in number, scattered, ascending, tolerably closely set, of a shining green colour, five-nerved, those at the middle of the stem 3 to 4 inches long, and 4 to 6 lines broad in the middle, the upper ones more distant from each other, shorter, and lance-shaped; flowers, usually solitary (sometimes two to six in number), nearly horizontal; perianth, white, fragrant, narrowly funnel-shaped, 5 to 7 inches long; tube, 2 or 3 inches long, scarcely widened above the base; segments, oblanceolate, obtuse in the expanded flower, falcate in the upper fourth of their length, 12 to 18 lines broad at two-thirds of their length from the base; inner ones

Dwarf White Japan Lily (*L. eximium*).

broader; filaments, white, 4 or 5 inches long; anthers, yellow, narrow, 6 to 9 lines long; pollen, yellow; ovary, 1 to 1 $\frac{1}{2}$ inches long, and, along with the slightly curved style, scarcely exceeding the stamens in length; stigma, 4 to 4 $\frac{1}{2}$ lines in diameter; capsule, narrowly oblong, obtuse-angled, umbilicated at the apex. Temperate regions of Japan, Oldham, 734, Maximowicz, &c.; China, Fortune, 57, 66, Reeves; Hong Kong, Capt. Urquhart; Formosa, Wilford, 548; Swinhoe; Oldham, 565; Capt. Champion; Loo-choo Islands, Capt. Beechey, C. Wright. For the various forms of this plant, see Duchartre, Obs. pp. 37-40. The finest variety of all is *L. eximium*, Court. Spae Mon. 14; Flore des Serres, t. 283-4.—*L. Jama-juri*, Siebold et De Vriese, Tuinbow Flora i., 319, t. 11.—*L. eximium Wilsonii*, Hort. Angl., is of taller growth, and has broader leaves and larger flowers, 8 or 9 inches long.

—*L. Takesima* and *abchasicum*, Hort., are forms of *longiflorum*.

6. *L. neilgherrense*.—Wight, Ic., t. 2,031-2.—*L. tubiflorum* Wight, Ic., t. 2,033-4.—*L. Wallichianum*, Wight, Ic., t. 2,035, non Schultes, fl.—*L. Metzii*, Steud. in Hohen. Ind. Or. Exsic., No. 954.—*L. neilgherrense*, Hort. Veitch. Lemaire; Ill. Hort., x. t. 353.—Bulb, globose, 2 or 3 inches long; scales, thick, lance-shaped; stem, 2 or 3 feet high, straight, smooth, decumbent for some length at the base; leaves, thirty to forty in number, of a shining green colour, ascending, firm, closely set, scattered (*i.e.*, not in whorls), distinctly three-nerved, the lower ones 3 or 4 inches long, and 12 or 13 lines broad in the middle; flowers, one to three in number, ascending, white, fragrant; perianth, narrowly funnel-shaped, 6 or 7 inches long; tube, 2 or

The Tube-flowered Lily (*L. neilgherrense*).

3 inches long, scarcely widened above the base; segments, oblanceolate-clawed, in the expanded flower falcate only at the apex, cuspidate, callous at the apex, downy, 15 to 18 lines broad at three-quarters of their length from the base; stamens, a little shorter than the perianth; anthers, narrow, yellow, 9 to 12 lines long; pollen, yellow; ovary, 12 to 14 lines long, and, along with the slender style (which is from 3 to 3 $\frac{1}{2}$ inches long), equal in length to the stamens; capsule, oblong, obtuse-angled. Temperate region of the Pulnies and Neilgherry Mountains, in the Indian Peninsula; Wight, Gardner, &c.—*L. tubiflorum* and *Wallichianum* (Wight), are forms with smaller and nar-

rower leaves (6 to 9 lines broad in the middle), and with narrower perianth-segments (12 to 15 lines broad).

7. *L. japonicum*.—Thunb. Fl. Japan, 133; Mém. Acad. Péters. iii., 205, t. v. fig. 2; Bot. Mag., t. 1,591; Lodd. Bot. Cab., t. 438; Reich. Exot., t. 88; Kunth, Enum. iv., 257; Miquel, Ann. Mus. Lug. Bat. iii., 157.—*L. odorum*, Planch., Fl. des Serres, t. 876-7.—Bulb, globose, perennial; stem, 1 to 2 feet high, straight, smooth, spotted with purple; leaves, twelve to twenty in number, scattered, ascending, dark green, more slender than those of *L. longiflorum*, smooth, lance-shaped, acute, five to seven-nerved, 8 to 12 lines broad in the middle, the lower ones 4 to 6 inches long; flowers, sweet-scented, usually solitary, white on the inside, and more or less tinged with purple on the outside; perianth, 5 or 6 inches long, broadly funnel-shaped, gradually widened from the base to the neck, where

it is from 15 to 18 lines in diameter; segments, oblanceolate-clawed, obtuse, in the expanded flower, falcate in the upper third part of their length, 15 to 18 lines broad at two-thirds of their length from the base; filaments, whitish-green, shorter than the perianth by one-third; anthers, thick, oblong, 5 or 6 lines long; pollen, red; ovary, 12 to 15 lines long (together with the style, a little longer than the stamens); stigma, 4 lines in diameter; capsule, obovoid, 2 inches long, deeply and obtusely six-angled. Temperate regions of Japan, Maximowicz; Islands of the Corea, Oldham, 869.—*L. Brownii*,

Brown's Japan Lily (*L. japonicum* var. *Brownii*).

Japan Lily (*L. japonicum*).

Mielli, *Flore des Serres*, t. 47 (*L. japonicum*, Bury, *Hexand.*, t. 2) is a tall, large-flowered form, with from twenty-five to thirty leaves, and with larger flowers, which are more deeply tinged with purple on the outside.

8. *L. Krameri*.—Hort. Teutschel, Hook. fil., *Bot. Mag.*, t., 6,058.—Stem, 3 or 4 feet high, slender, terete, smooth, spotted with purple; leaves, distant from each other, scattered, fifteen or sixteen in number, linear-lance-shaped, acuminate, very shortly stalked, firm, green, five-nerved, with minute papillæ on the margins, 6 to 9 inches long, and 6 to 9 lines broad; perianth fragrant, horizontal, solitary, broadly funnel-shaped, whitish with a slight reddish tinge, 6 or 7 inches long, gradually narrowed from the base to the neck; segments, oblanceolate-oblong, in the expanded flower, falcate above the middle in the upper third part, the outer ones 15 or 16, and the inner ones 20 or 21, lines broad; filaments about half the length of the perianth; anthers, of a dull brown colour, 8 or 9 lines long; pollen, red; ovary, 15 to 18 lines long, half the length of the slightly curved style; stigma, 4 to 4½ lines in diameter. Japan; flowers in the beginning of July. Probably a hybrid between *L. speciosum* and *L. japonicum*, having leaves like those of the former, and perianth and anthers like those of the latter (v. v. ex hort. Wilsoni).—Var. *Barrianum*, Baker.—A smaller and slenderer form, with more numerous and more crowded leaves, which are three-nerved and from 2½ to 3 lines broad; perianth, white, 4 inches long; outer segments, 9 or 10 lines broad in the middle, inner ones, 15 to 18 lines broad; ovary, an inch long; style, ½ inch long; anthers, ½ inch long (v. v. in hort. Barr).

Kramer's Japan Lily (*L. japonicum* var. *Krameri*).

9. *L. nepalense*.—D. Don, *Wern. Trans.* iii., 412; *Prodr. Nep.* 52; Wallich, *Pl. Asiat. Rar.* iii., 67, 291, *Cat.* 5,078; Kunth, *Enum.* iv., 267—*L. ochroleucum*, Wall. in *hb. Lindley*.—Bulb, not known to me; stem, 2 or 3 feet high, straight, slender, smooth; leaves, thirty to fifty in number, scattered, of a shining green colour, ascending, smooth, lance-shaped, acute or linear, the lower ones 3 or 4 inches long, 6 to 9 lines broad in the middle, distinctly five to seven nerved,

the upper ones shorter and distant from each other; flowers, solitary, or few in an umbel, slightly fragrant (pedicels with bracts at the base in a whorl of reflexed leaves), or few in a loose raceme, the

Buff Nepal Lily (*L. nepalense*).

lower pedicels ascending, 2 or 3 inches long, nodding at the top; perianth, 4 or 5 inches long, broadly funnel-shaped, whitish-yellow, more or less tinged with purple on the inside, often marked with scattered dots; segments, oblanceolate-clawed, bluntish, in the expanded flower, falcate in the upper third part, 6 to 12 lines broad at two-thirds of their length from the base; stamens, shorter than the perianth by one-fourth; anthers, narrow, 6 or 7 lines long; pollen, yellow; ovary, 9 to 12 lines long, together with the style, a little longer than the stamens; capsule, ovate, 2 inches long, obtuse-angled. Temperate regions of the Western and Central Himalayas, from Gurwhal and Kumaon to Nepaul. Wallich, Thomson, Jacquemont, &c.

10. *L. candidum*.—*L. Sp.*, 433; *Bot. Mag.*, t. 278; *Red. Lil.*, t. 199; Bury, *Hexand.*, t. 38; Reich., *lc. Germ.*, t. 445; Kunth, *Enum.*, iv., 266.—Bulb, ovoid, perennial, large, yellowish; first leaves produced in winter, sessile, oblanceolate, 1½ to 2 inches broad; stem, 3 to 4 feet high, straight, smooth, blackish-green; leaves, 100 or more in number, scattered, ascending, green, acute,

Monstrous White Lily (*L. candidum* var. *monstrosum*).

Common White Lily (*L. candidum*).

two to five-nerved, with minute papillæ on the margin, those at the centre of the stem linear, 3 to 6 inches long, the lowest ones oblanceolate obtuse, the upper ones gradually smaller, the highest lance-shaped, 1 to 1½ inches long, and pressed close to the stem; raceme, short, deltoid, containing from six to twenty flowers, and, when fully expanded, 6 to 8 inches broad; lower flowers nodding; bracts, lance-shaped or linear; pedicels, ascending, the lowest ones 2 or 3 inches long, often with small bracts; perianth, white, fragrant, broadly funnel-shaped, 2 or 3 inches long, gradually widened from the base to the neck (where it is 1½ inches in diameter); segments, in the expanded flower, falcate in the upper third part, obtuse, downy at the apex, 6 to 9 (or, rarely 12) lines broad above the middle; stamens, shorter than the perianth by one-third; anthers, yellow, 5 or 6 lines long; style, together with the ovary, much longer than the stamens, nearly as long as the perianth. Southern Europe, from Corsica to Northern Persia and the Caucasus.—Var. *striatum*, *Flore des Serres*, t. 735, is a form with flowers streaked with purple on the outside.—Var. *spicatum*, Hort., is an abnormal form, the flowers being abortive, and the bracts dilated, white, and petaloid.—Var. *peregrinum*, Linn.—*L. peregrinum*, Mill. Dict., No. 2; Hayne, *Arzne.*, viii., 27; Sweet, *Brit. Flow. Gard.*, ser. ii., t. 367. A slenderer form, with a purple stem, narrower leaves, and segments of perianth narrower, longer, more acute, and more spatulate. A garden variety, long in cultivation, not yet found in a wild state.

11. L. Belladonna.—Hort. Leichtlin.—Stem, a foot or more high, slender, smooth, terete, green; leaves, about twenty in number, lance-shaped, very shortly stalked, distant from each other, green, smooth, acuminate, patent, $1\frac{1}{2}$ to 2 inches long, 3 or 4 lines broad in the middle; flowers, one to three in number, the terminal ones erect at first, the lateral ones horizontal when expanded; perianth, broadly funnel-shaped, 3 inches long, of a deep reddish colour on both sides, tinged with green at the base outside; tube, gradually widened from the base to the neck; segments, oblanceolate, not dotted, in the expanded flower falcate in the upper third part, 8 to 12 lines broad at two-thirds of their length from the base, the inner ones broader; stamens, shorter than the perianth by one-fourth; anthers, narrow, reddish, 3 or 4 lines long; style, slightly curved, and, together with the ovary, longer than the stamens; stigma, small. The plant has the habit of *L. speciosum*, with a perianth like that of *L. candidum*, only reddish. Described from Max Leichtlin's figure. It is, perhaps, a garden hybrid from *L. speciosum* and *L. longiflorum*.

12. Washingtonianum.—Kellogg, Proc. Calif. Acad., ii., 13; Wood, Proc. Acad. Phil., 1868, 166; Baker, Gard. Chron., 1871, 709, t. 142; Regel, Gartenf., t. 170; Flore des Serres, t. 1, 975.6.—*L. Bartramii*, Nuttall, herb.—Bulb, oblique, white, sub-rhizomatous, with small lance-shaped scales; stem, 3 to 5 feet high, terete, smooth, green, racemose at the top, bare below the raceme; leaves, in six to nine whorls, each containing from five to twelve leaves, or the upper ones scattered, oblanceolate, patent, sessile, smooth, 3 or 4 inches long, 8 to 12 lines broad above the middle, acute, green, gradually narrowed from the middle to the base; lateral veins, oblique and indistinct; raceme, from 6 inches to 1 foot long, containing from 12 to 20 flowers when expanded, 8 or 9 inches broad, pedicels ascending, the lower ones, 2 to 4 inches long; bracts, small, oblanceolate or linear; perianth, fragrant, funnel-shaped, whitish, $2\frac{1}{2}$ to 3 inches long, slightly tinged with reddish or purple on the inside; dots, few, small, lilac-coloured, scattered; segments, oblanceolate, 6 to 8 lines broad at two-thirds of their length from the base (from which point they are gradually narrowed to the base), falcate in the upper third or fourth part when the flower is fully expanded; stamens, shorter than the perianth by one-fourth; anthers, yellow, 5 or 6 lines long; ovary, 8 or 9 lines long, about one-third the length of the curved style. California, in woods on the Sierra Nevada, &c. — Jeffray, 1, 139; Bridges, 270; W. Lobb, 248.—Var. *purpureum*, Hort. Bull.—A smaller and slenderer form; stem, 12 to 18 inches high; leaves, 1 to $1\frac{1}{2}$ inches long; flowers, in umbels of four to eight; segments, more falcate, 5 or 6 lines broad, of a deep vinous-purple colour, and with small dots scattered over the entire inner surface; style, 9 to 12 inches long. California, in the Yosemite Valley. Extensively cultivated in English gardens in 1873.

Nevada Lily (*L. Washingtonianum*).

§ **Archelirion** (Baker).—Perianth, broadly funnel-shaped, or campanulate; segments, ovate, or oblong-lance-shaped, and deeply falcate in the expanded flower, dotted on the inner surface, and with papillæ on the lower part; groove on the keel very deep; stamens, diverging widely from the curved style.

13. L. tigrinum.—Gawl., Bot. Mag., t. 1, 237; Red. Lil., t. 395 and 475; Kunth, Enum. iv., 259.—*L. speciosum*, Andrews, Bot. Rep., t. 586, non Thunberg.—Bulb, perennial, globose, with oblong-lance-shaped, acute scales; stem, 2 to 4 feet high, blackish or brownish, with a white cobweb-like pubescence; leaves, deep green, scattered, smooth, ascending, firm, linear, 3 or 4 inches long, 3 to 6 lines broad in the middle, five to seven-nerved, the upper ones shorter, and bearing brownish red bulbils in the axils; raceme, consisting of three to ten (rarely twenty to twenty-five) flowers, broad, deltoid when expanded, sometimes 12 to 15 inches in length and breadth; bracts, small, ovate; pedicels, divaricated, straight, nodding at the top, the lower ones 3 or 4 inches long, and often furnished with bracts; perianth, 3 or 4 inches long, and of a brilliant red colour, or tinged with orange; segments, broadly falcate, acuminate, callous at the apex, downy, 9 to 18 lines broad below the middle, the inner ones much broader, all with large dark-purple dots on the inner

surface; claws, covered with numerous black-headed papillæ, groove on the keel very deep, and with pubescent edges; filaments, crimson, 2 to $2\frac{1}{2}$ inches long; anthers, blackish, 6 to 8 lines long; pollen crimson; ovary, green, 9 to 12 lines long; style, $1\frac{1}{2}$ to 2 inches long, very much curved. I have not seen the capsule. Temperate regions of Japan and China. Flowers at the end of July and during the whole of the month of August. For the forms in cultivation see T. Moore, Florist, 1873, 14.—*Splendens*, Flore des Serres, t. 1, 932; Wilson, Journ. Hort., 1873, 251, with a figure; Floral Mag., t., 509 (Leopoldi, Hort. is a large-flowered, very late-blooming form, with larger dots, broader leaves, and stem with less cobweb pubescence.—*Fortunei* is a form which does not bloom so late, and has the stem densely covered with less cobweb-like pubescence.—*Lishmanni*, Moore, Florist, 1873, 13, with a figure, is a form which has the dots confined to the central part of the segments, the upper part and the base being without dots.—*Erectum* has the pedicels less divaricated, and the flowers nearly erect.

14. L. oxypetalum, Baker.—*Fritillaria oxypetala*, Royle.—Ill. Him., 388? Hook., Bot. Mag., t. 4, 731; Lemaire, Fleur., t. 422.—

Snake's-head Lily (*L. oxypetalum*).

Lilium triceps, Klotzsch, Reise, Wald., 33, t. 93.—Bulb, oblong; scales, few, lance-shaped, acuminate, $1\frac{1}{2}$ inches long; stem, slender, terete, green, one-headed, smooth, 1 to $1\frac{1}{2}$ feet high; leaves, twenty to thirty in number, at first densely rosulate, scattered, ascending, green, smooth, lance-shaped or linear, 2 or 3 inches long, and 3 to 6 lines broad in the middle; perianth, horizontal, broadly funnel-shaped, 15 to 18 lines long; segments, oblong, acute, broadly imbricated, 8 or 9 lines broad in the middle, purplish, tinged with green on the back, dotted with purple on the lower half of the inner surface, and with numerous papillæ crowded together at the base; claw, short, deeply furrowed and bearded on the outside; stamens, shorter than the perianth by one-third; anthers, purplish, 3 or 4 lines long; filaments, diverging; ovary, club-shaped, 5 or 6 lines long; style, straight, shorter than the ovary; capsule, obovoid-oblong, 9 to 12 lines long, obtuse-angled; valves, emarginate at the apex. Temperate regions of the Western Hima-

Showy Japan Lily (*L. speciosum*).

Red-spotted Japan Lily (*L. speciosum* var. *rubrum*).

layas, Hoffmeister; Kumaon to Pindari, at an altitude of 12,500 feet; Strachey and Winterbottom.

15. L. speciosum.—Thunb., Linn. Trans., ii., 332; Bot. Reg., t. 2,000; Zuccarini, in Sieb. Fl. Jap., iii., 31, t. 12, and t. 13, fig. 1;

Kunth, Enum. iv., 259; Bot. Mag., t. 3,785; Flore des Serres, t. 276.—*L. lancifolium*, Mussche, Paxt. Mag., v., 267, with a figure, non Thunb.—Bulb, perennial, globose, brown or brownish-red; scales, lance-

shaped, an inch long, somewhat loosely set; stem, 2 or 3 feet high, straight, terete, smooth, green, or spotted with red; leaves, twelve to twenty in number, scattered, distant from each other, very shortly stalked (the stalk pressed close to the stem), oblong-lance-shaped, acute or acuminate, of a shining green colour, firm, smooth, rounded at the base, the lower ones 5 to 6 inches long, 15 to 18 lines broad in the middle, and with five to seven distinct nerves distant from each other; raceme, deltoid, containing from three to ten

flowers; pedicels, divaricated and furnished with bracts, the lowest 3 to 5 inches long, the central ones nearly erect, the lateral ones nodding at the top; perianth, 3 or 4 inches long; segments, ovate-lance-shaped, deeply falcate, 12 to 21 lines broad, the inner ones broader, white, usually more or less suffused with red, dotted with red on the inner surface, and with numerous papillæ; groove on keel deep and smooth; filaments, diverging widely, $2\frac{1}{2}$ to 3 inches long; anthers, narrow, 9 to 12 lines long; pollen, saffron or red; ovary, 1 inch long; style, slender, very much curved, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long; capsule, obovoid-oblong, 2 inches long, obtuse-angled, umbilicated at the apex. Temperate region of Japan, flowers in the beginning of August. For the forms in cultivation, see Masters, Gard. Chron., 1872, p. 1,522.—Punctatum, Lemaire (*lancifolium*, Paxt. Mag., v. t. 267, *albiflorum*, Hook., Bot. Mag., t. 3,785), is a form which has white flowers with red dots and papillæ; Tametomo, Zucc., and Spae. (*eximium*, Hort. olim; *L. Broussartii*, Morren, Mém. Acad. Roy. Brux., Feb., 1834, with a figure; *vestale*, Masters, loc. cit.), is a variety which has white flowers without dots; Krætzneri, Duchartre, has white flowers, the segments of which are marked with broad streaks of green on the outside.

16. *L. auratum*.—Lindl., Gard. Chron., 1862, 644b; Hook., Bot. Mag., t. 5,338; Flore des Serres, t. 1,528-1,531; Ill. Hort., ix., t. 338; Rev. Hort., 1867, t. 371; Miquel, Ann. Mus., iii., 156.—*L. Dexteri*, Hovey, Mag. Hort., Aug. 1862.—*L. Wittei*, Suringar in K. Koch, Wochen, 1867, 294.—*L. speciosum imperiale*, Hort., Siebold.—Bulb, exactly like that of *L. speciosum*; stem, 2 to 4 feet high, green, or tinged with purple, slender, terete, smooth; leaves, 20 to 30 in number, scattered, distant from each other, very shortly stalked (stalk pressed close to the stem), lance-shaped, acuminate, of a deep green colour, smooth, firm, five-nerved, the lower ones 6 to 9 inches long and 9 to 15 lines broad; raceme, deltoid, containing from three to ten flowers;

pedicels, divaricated and furnished with bracts; perianth, 5 to 7 inches long; segments, broadly falcate, 1 to 2 inches broad in the middle (the inner ones broader), white, usually streaked with yellow in the middle, and with scattered purple dots and papillæ on the lower part of the inner surface; groove on the keel, distinct and with smooth edges; filaments, 3 to $3\frac{1}{2}$ inches long; anthers, narrow, 9 to

Golden-rayed Japan Lily (*L. auratum*).

Red-rayed Japan Lily (*L. auratum* var. *rubrum vittatum*).

12 lines long; pollen, red; ovary, 12 to 14 lines; style, slender, very much curved, $2\frac{1}{2}$ to $3\frac{1}{2}$ inches long; capsule, 3 inches long, oblong, longer and narrower than that of *L. speciosum*, emarginate at the apex.—Japan, Oldham, 186, Maximowicz. These are forms approaching *L. speciosum* with flowers streaked with red; some of these have from twenty-five to thirty broader leaves, and others from forty to fifty narrower leaves.—*L. Wittei*, Suringar, is a variety with white undotted leaves.

§ **Isolirion** (Baker).—Perianth, broadly funnel-shaped, standing erect for a considerable time, usually of a brilliant red or yellow colour; segments, oblong, lance-shaped, spatulate, or clawed at the base, with dots and papillose, lamellæ on the inner surface, and with a deep groove on the keel; stamens, diverging on every side from the erect style.

17. *L. philadelphicum*.—*L. Sp.* 435; Miller, Ic. t. 165, fig. 1; Bot. Mag., t. 519; Red. Lil., t. 104; Lodd. Bot. Cab., t. 976; Herb. Amat., t. 92; Bot. Reg., t. 594; Kunth, Enum. iv., 263.—Bulb, small, annual, stoloniferous; scales, fragile, thick, nearly club-shaped; stem, 1 to 3 feet high, green, slender, terete, smooth; leaves, twenty to thirty in number, lance-shaped, or linear, patent, slender, smooth, finely-nerved, sessile, the lower ones 3 or 5 inches long, 3 to 6 lines broad in the middle, arranged in whorls of four to six, or six to eight leaves, or few or many scattered; flower, solitary, terminal,

Canadian Whorl-leaved Lily (*L. philadelphicum*).

erect, or a few in an umbel; pedicels, 2 or 3 inches long, ascending, with a whorl of large leafy bracts at the base; perianth, 2 or 3 inches long, of a brilliant yellowish-red colour; segments, oblong-lance-shaped, 6 to 10 lines broad in the middle, with a distinct claw 6 to 8 lines long at the base, marked with large scattered purple dots on the lower half of the inner surface; groove, smooth, deep, margined on the edges by the revolute claws; stamens, shorter than the perianth by one-third; anthers, 5 or 6 lines long; pollen, red; ovary, 9 or 10 lines long, about half the length of the style; capsule, narrowly-obovoid, obtuse-angled. North America, from Canada to Carolina.—Var. *L. andinum*, Nuttall, Gen. i., 221.—*L. umbellatum*, Pursh, Flora i., 229.—Var. *wansharaicum*, Hort. Leichl.; Duchartre, Obs. 88.—Leaves, linear, all scattered. Rocky Mountains, Douglas, Bourgeau, &c.

18. *L. medeoloides*.—A. Gray, Mem Amer. Acad., vi., 415; Miquel, Ann. Mus. Lug. Bat., iii., 156.—*L. maculatum*, Thunb., Linn. Trans., ii., 334; Mem. Acab. Petrop., iii., 204, t. 5, fig. 1?—*L. canadense*, Thunb., Fl. Jap., 204?—Stem, 1 to 2 feet high, slender, smooth, terete, flexuose; leaves, mostly arranged in a single whorl of seven to fourteen; leaves, above the middle of the stem, oblanceolate, patent, tender, smooth, green, 4 to 6 inches long, 9 to 15 lines broad above the middle, acute, with two to four distinct lateral veins; there are sometimes a few scattered leaves above the whorl; flowers, solitary, or two to three in an umbel; pedicels, short, erect at the top; perianth, 12 to 15 lines long, erect, of an open funnel-shape, and brilliant orange-red colour, marked on the inside with a few claret-coloured dots; segments, lance-shaped, slightly falcate from the base, callous at the tip, channelled, downy, 3 to 4 lines broad in the middle, slightly spatulate at the base; groove, on the keel indistinct, smooth; filaments, half the length of the perianth; anthers, 4 to 5 lines long; ovary, club-shaped, 4 lines long; style, erect, a little shorter.—Japan, near Hakodadi, C. Wright. The Korean Island, Herschel, in inundated woods, where it flowers in June. Oldham, 873; it approaches most closely to *L. Martagon* and *L. avenaceum*; but is easily distinguished by its erect flowers, falcate (not revolute) segments, and short stamens and pistil.

19. *L. concolor*.—Salisb. Parad., t. 47; Kunth, Enum. iv., 259 and 673; Fisch and Mey. Ind. Sem. 1839, 55.—*L. sinicum*, Lindl. in Paxt. Flow. Gard., vol. ii., Misc. 115, t. 193; Lemaire, Ill. Hort., t. 100; Van Houtte, Flore des Serres, t. 1,206.—Bulb, ovoid, perennial, small; scales, few, whitish, oblong, acute; stem, slender, about a foot high, slightly pubescent, suffused with purple; leaves, twenty to thirty in number, ascending, scattered, lance-shaped, of a deep green colour, acute, $2\frac{1}{2}$ to 3 inches long, 4 to 6 lines broad in the middle, indistinctly seven-nerved, fringed with papillæ on the edges; flowers, one to three in number; pedicels, somewhat downy, purple, ascending, $1\frac{1}{2}$ to 2 inches long, sometimes bracteolated; perianth, 15 to 18 inches long, of a dark crimson colour, without spots on the inside,

paler on the outside; segments, broadly falcate, lance-shaped, 4 to 9 lines broad in the middle, callous at the tip, somewhat downy, slightly papillose at the base; groove on the keel, deep, with smooth edges; filaments, half the length of the perianth; anthers, 3 or 4 lines long; pollen, red; ovary, club-shaped, 5 or 6 lines long, deeply furrowed; style, club-shaped, 3 or 4 lines long, shorter than in any other species; capsule, 1 inch long, obovoid-oblong, obtuse-angled. China; flowers in the end of June.—*L. concolor*, Bot. Mag. 1,165, is a form in which the segments have a few dark spots on the inside, near the base.—Var. *L. Buschianum*, Lodd, Bot. Cab., t. 1,628.—*L. pulchellum*, Rev. Hort., 1862, 131, with a figure.—*L. concolor*, var. *sinicum*, Bot. Mag., t. 6,005. This variety sometimes grows taller, and has a larger and solitary bulb (the scales of which are few and broad), narrower dark green leaves, flowers sometimes four to six in number, segments of the perianth a little broader and of a brilliant crimson on the inner surface, the lower half of which is covered with numerous scattered small blackish dots; capsule, narrowly obovoid, $\frac{1}{2}$ inch long, umbilicated at the apex. Southern Siberia.—Var. *L. partheneion*, Sieb. and De Vriese, Tuinbow Flora, ii., 341, with a figure, scarcely differs from *L. Buschianum*, except in its slenderer habit, shining leaves, and caespitose bulbs. Japan.—*L. Coridion*, Sieb. and De Vriese, loc. cit., Duchartre, Obs. 42, is the same plant with yellow flowers.—Var. *L. pulchellum*, Fisch. and Mey., Ind. Sem. Petr., 1839, 56; Kunth, Enum. iv., 266, 676; Regel, Gartenfl., 1860, 81, t. 284, fig. 2.—Bulb, ovoid, scarcely an inch long; stem, very slender, about a foot high; leaves, twelve to twenty in number, narrowly linear, ascending, 2 to $2\frac{1}{2}$ inches long, and $1\frac{1}{2}$ to 2 lines broad; perianth, often solitary, red, 12 to 15 lines long; segments, oblan- ceolate, obtuse, 3 to 5 lines broad in the middle, covered on the lower half with numerous minute blackish dots; filaments, 5 or 6 lines long; ovary, 3 or 4 lines long, longer than the style. Eastern Siberia. A yellow-flowered variety is cultivated in Japan, Maximowicz; on stony hills in Chinese Mongolia, Meyer and Turczaninow, in herb. DC.

Crimson Erect-flowered Lily (*L. concolor*).

20. *L. bulbiferum* (Parkinson, Parad., 37, t. 2).—*L. Sp.* 433 ex parte; Jacq., Fl. Austr., t. 226; Bot. Mag., t. 1,018; Fisch. and Mey., Ind. Sem., 1839, 54; Kunth, Enum., iv., 264, 674; Regel, Gartenfl., 1872, 231, with a figure of the bulb.—Bulb, ovoid, perennial; scales, few, broad, acute; first shoots, broad, obtuse, tinged with red; stem, 2 to 4 feet high, straight, furrowed, spotted with purple, covered with white cobweb-like down on the upper part; leaves, fewer and more ascending than in *L. croceum*, the lower ones about 3 inches long and 3 to 6 lines broad in the middle (the upper ones drawn back), and bearing bulbils in the axils; flowers, in wild specimens, one to three in number, in cultivated plants often more numerous, and arranged in an umbel or deltoid raceme; pedicels, thick, short, spotted with purple, and covered with a white cobweb-like down; perianth, 2 to $2\frac{1}{2}$ inches long, erect, scentless, of a brilliant red colour, often tinged with orange at the bottom; segments, oblong-spathulate, 9 to 15 lines broad in the middle, the inner ones less clawed than in *L. croceum*, all with black dots, and numerous lamellæ and papillæ on the inner surface; groove, $\frac{1}{2}$ inch long, very deep, with pilose edges; filaments, 18 to 21 lines long; anthers, 3 or 4 lines long; pollen red; ovary, 7 or 8 lines long, half the length of the style; capsule, $1\frac{1}{2}$ inches long, obovoid, obtusely six-angled, umbilicated at the top. Central Europe, and South-eastern Scandinavia, flowering in our gardens amongst the earliest, blooming in June, before *L. croceum* and *L. davuricum*.—*L. latifolium*, Link, Enum., i., 321, is a large-growing garden form with broad leaves.—*L. humile*, Miller, Dict. No. 4, is a

Tiger Lily (*L. tigrinum*).

small form with narrow leaves.—*L. pubescens*, Bernh., Kunth, Enum., iv., 265, is probably a garden form with peduncles thickly covered with cobweb-like down. For its various forms, see Parkins, Parad., 38.

21. *L. croceum* (Fuchs).—Chaix. in Vill. Delph., i., 322; Kunth, Enum., iv., 265 and 675; Fisch. and Mey., Ind. Sem., vi., 56; Gran. Flor. France, iii., 182.—*L. bulbiferum*, DC., Fl. France, iii., 202; Bot. Mag., t. 36 (the figure much above the natural size).—*L. aureum*, Parkinson, Paradisus, 37, t. 3.—Bulb, globose, perennial; scales, large, ovate-lance-shaped, not narrowed at the middle; first shoots, broad, obtuse, tinged with red; stem, 3 to 6 feet high, stout, furrowed, green, spotted with purple on the upper part, more or less covered with cobweb-like down; leaves, 50 to 100 in number, scattered, very close, patent, or the lower ones slightly squarrose, linear, the lower ones 3 or 4 inches long, 3 or 4 lines broad, three to five-nerved, sessile, smooth, firm, never bearing bulbils in the axils; flowers, in wild specimens, often solitary, in cultivated plants often

Orange Lily (*L. croceum*).

ten to twenty in number, arranged in a deltoid raceme or umbel; pedicels, ascending, 2 or 3 inches long, covered with white cobweb-like down; perianth, erect, broadly funnel-shaped, 2 to $2\frac{1}{2}$ inches long when fully expanded, 3 inches broad, at first covered with white cobweb-like down on the outside; outer segments, oblong-lance-shaped, 8 or 9 lines long, broad below the middle, spatulate at the base; inner ones, ovate-lance-shaped, 12 to 14 lines broad below the middle, distinctly clawed at the base, all of a brilliant orange colour scarcely tinged with crimson, cuspidate at the apex, somewhat downy, imbricated in the expanded flower, marked with numerous dots and lamellate papillæ; groove $\frac{1}{2}$ inch long, very deep, with pilose edges; filaments, 15 to 18 lines long; anthers, 4 lines long; pollen, red; ovary, 8 or 9 lines long; style, 12 to 14 lines long; capsule, obovoid, $1\frac{1}{2}$ inch long, somewhat acutely angled. Switzerland, France, Northern Italy; long grown in gardens under many forms. Flowers in the beginning of July, after *L. bulbiferum*.

22. *L. davuricum*.—Gawl., Bot. Mag., sub. t. 1,210; Kunth, Enum., iv., 264; Regel, Gartenfl., t. 740, and 1872, 295.—*L. pennsylvanicum*, Gawl., Bot. Mag., t. 872.—*L. spectabile*, Link, Enum., i., 321; Reich., Ic. Exot., t. 30; Fisch. and Mey., Ind. Sem. vi., 58; Kunth, Enum., iv., 676; Regel, Gartenfl., t. 349, 1872, 231, with a figure of the bulb.—Bulb, globose, perennial; scales, small, fiddle-shaped, acute, white, brittle, contracted in the middle; first shoots, narrow, acute, tinged with brown; stem, 2 or 3 feet high, slender, green, slightly covered with white cobweb-like down in the upper part; leaves, twenty to fifty in number, ascending, sessile, linear, three-nerved, the lower ones 4 or 5 inches long, 3 or 4 lines broad in the middle, never bearing bulbils in the axils; flowers, in wild specimens, often solitary, in cultivated plants, few, in umbels or short racemes; pedicels, naked or slightly covered with cobweb-like down; perianth of a brilliant red colour, 2 to $2\frac{1}{2}$ inches long when fully expanded, 3 to $4\frac{1}{2}$ inches broad; segments, oblong-lance-shaped, 9 to 12 lines broad below the middle, scarcely imbricated in the expanded flower, less dotted and lamellated than in *L. croceum* and *L. bulbiferum*, spatulate at the base; groove, very deep, 8 or 9 lines long, with pilose edges; filaments, red, 18 to 21 lines long; anthers, 5 or 6 lines long; pollen, red; style, twice the length of the ovary; capsule, $1\frac{1}{2}$ to 2 inches long, obtuse-angled. Central and Eastern Siberia, from the Altai Mountains to Kamtschatka. It flowers in our gardens in July along with *L. croceum*, and after *L. bulbiferum*.—*L. umbellatum*, of most gardens, is a luxuriant garden form of *L. davuricum*. For its varieties, see Regel, Gartenfl., 1872, 295.

Umbel-flowered Lily (*L. umbellatum*) *davuricum*).

23. *L. elegans*.—Thunb., Mem. Acad. Petr., iii., 203, t. 3, fig. 2.—*L. bulbiferum*, Thunb., Linn. Trans., ii., 333.—*L. philadelphicum*, Thunb., Fl. Jap., 135.—*L. Thunbergianum*, Schultes fil., Syst. Veg. vii., 415; Lindl. Bot. Reg., 1839, t. 38; Maund. Bot., t. 158; Regel., Gartenfl. 1872, 296.—*L. aurantiacum*, Paxt. Mag., vii., 127, with a figure.—Bulb, like those of *L. bulbiferum* and *L. croceum*; stem, about a foot high, smooth, or slightly covered with cobweb-like down, or pilose, stout, furrowed; leaves, twenty to thirty in number, ascending, scattered, firm, deep green, smooth, distinctly five to seven nerved, the lower ones 3 to 4 inches long, the upper ones shorter, 6 to 12 lines broad in the middle, not bearing bulbils in the axils; perianth, usually solitary, 3 to 3½ inches long, when fully expanded 5 or 6 inches broad, of an orange-red colour; segments oblong, spatulate, obtuse, scarcely dotted, much less lamellated and papillose than those of *L. davuricum*, outer ones 12 or 13 lines, and inner ones 15 to 18 lines broad in the middle; groove, distinctly excavated, 8 or 9 lines long, with pilose edges; filaments 1½ to 2 inches long; anthers, 4 or 5 lines long; ovary, 1 inch long, half the length of the style; capsule, obovoid, 2 inches long, sub-acutely six-angled, one half longer than its breadth. Japan; it flowers in our gardens in the beginning of July, under very many forms, of which the following are the most notable:—Var. 1, *brevifolium*, Baker and Dyer, Gard. Chron., 1872, 1,356.—*L. alternans*, hort.; leaves, broader and shorter, the lower ones 2 to 2½ inches, the upper ones 1 to 1½ inches long, all 7 to 9 lines broad, and of a deep green colour; perianth, less open, of a pale red colour throughout, with a few black dots at the bottom; filaments and style a little longer. Var. 2, *bicolor*, Moore, Floral Mag., t. 104.—*L. pictum*, hort. Siebold.—*L. aurantiacum*, hort. Krelage; stem, scarcely a foot high; leaves, about forty in number, narrower, the lower ones 4 to 6 lines broad; perianth, 3 to 3½ inches long; segments, broader than in any other variety (the inner ones 18 to 21 lines broad), with yellow centre, red sides, and a few dots near the base.—Var. 3, *pardinum*, Moore, Florist, 1861, 121, with a figure. This scarcely differs from var. 2, except in having a taller stem (2 to 3 feet), and the flowers few and in an umbel. Var. 4, *alutaceum*, Baker and Dyer, Gard. Chron., loc. cit.—*L. Thunbergianum aureum nigro-maculatum*, Flores des Serres, t. 1,627; stem, dwarf; leaves about thirty in number; flowers, solitary; perianth of a pale apricot colour; inner segments, 12 to 13 lines broad, with numerous purplish dots on the lower half.—Var. 5, *armeniaceum*, Baker and Dyer, loc. cit. Stem, about a foot high; leaves, thirty to forty in number, the lower ones linear; flowers one or two in number, orange, not dotted, and without lamellæ or papillæ; segments 9 to 12 lines broad.—Var. 6, *citrinum* hort., Wilson, scarcely differs from *L. armeniaceum*, except in having the stem 2 to 2½ feet in height, the leaves lance-shaped, and flowers two to three in number.—Var. 7, *sanguineum*, Lindl., Bot. Reg., 32, t. 50. Stem, 1 to 1½ feet high; leaves, about forty in number, lance-shaped; flowers one to two in number; segments broad, blood-red, slightly tinged with orange, and with a few small dots near the base; papillæ and lamellæ nearly obsolete.—Var. 8, *atrosanguineum*, Baker and Dyer, loc. cit.—*L. coruscans*, hort. Stem, 1 to 1½ feet high; leaves, lance-shaped; flowers, usually solitary; segments, broad, deep red, with numerous dots on the lower half; papillæ and lamellæ, numerous and only slightly raised.—*L. hæmatochroum*, Lemaire, Ill. Hort., t., 503, is a similar form, with darker livid red flowers.—Var. 9, *fulgens*, Morren, in Spæe Mem., 29; Lemaire, Ill. Hort. t. 657, approaches *L. davuricum*. Stem, 1 to 1½ feet high; leaves, about forty in number, linear; flowers, often four to six in number, of a deep red colour; dots, lamellæ, and papillæ, almost obsolete.—*L. venustum*, Kunth, Flore des Serres, t. 652, is a similar form with a more brilliant flower more tinged with orange.—*L. Wilsoni*, hort., according to Max Leichtlin, is probably a hybrid between *L. elegans* and *L. speciosum*.

Thunberg's Orange Lily (*L. (Thunbergianum) elegans*).

24. *L. Catesbæi*.—Walt., Fl. Carol., 123; Bot. Mag., t. 259; Lodd., Bot. Cab., t. 807; Sweet, Brit. Flow. Gard., ser. ii., t. 185; Kunth, Enum., iv., 263.—*L. spectabile*, Salisb., Stirp. Rar., t. 5, non Link.—*L. carolinianum*, Catesby, Car., ii., t. 58, non Michx.—Bulb, exactly like that of *L. philadelphicum*; stem, 1 to 2 feet high, slender, terete, smooth, green; leaves, twenty to thirty in number, scattered, ascending, smooth, green, lance-shaped, or linear, the

lower ones 2 or 3 inches long, 4 to 6 lines broad, the upper ones gradually smaller; perianth, solitary, erect, broadly funnel-shaped, 3 or 4 inches long, of a brilliant orange-red; segments, oblong-lance-shaped, 6 to 12 lines broad in the middle, distinctly cuspidate for some length, and with purple spots scattered over the inner surface; claw, channelled at the base, 9 to 15 lines, with revolute margins; filaments, 2½ to 3 inches long; anthers, narrow, 4 to 6 lines long; pollen, red; ovary, 9 to 12 lines long; style, slender, twice the length of the ovary. North America, from Georgia and Carolina to Florida.

§ **Martagon** (Endl.).—Flowers, in racemes, nodding, dotted, usually of a brilliant red or orange colour; perianth, broadly campanulate; segments, lance-shaped, deeply falcate; grooves, deep; stamens, diverging on all sides from the curved style.

Catesby's Orange Lily (*L. Catesbæi*).

25. *L. canadense*.—Linn. Sp., 435; Bot. Mag., t. 800 and 858; Kunth, Enum., iv., 258; Bury, Hexand., t. 12; Flore des Serres, t. 1,174.—*L. penduliflorum*, DC. in Red Lil., t. 105.—*L. pendulum*, Spæe, Mem., 28.—*Martagon sive Lilium canadense maculatum*, Parkins, Parad., 32., t. 2.—Bulb, annual, emitting runners 5 or 6 inches long; scales, thick, obtuse, scarcely ½ inch long; stem, 1½ to 2 feet high, slender, smooth, terete, green leaves, often arranged in four or five regular distant whorls of four to eight leaves (the whorls being, however, sometimes more or less broken up), oblanceolate, acute, 3 or 4 inches long, 6 to 9 lines broad above the middle, green, slender, five to seven-nerved, the veins sometimes ciliated; flowers, solitary, or a few in an umbel or corymb; pedicels, 2 to 6 inches long, nodding very much at the top, sometimes bracteolate; perianth, 2 to 2½ inches long, broadly funnel-shaped, brilliant orange-red; segments, oblanceolate, 6 or 7 lines broad, falcate above the middle, with numerous claret-coloured spots on the inner surface, lamellated in the upper part; groove, distinctly sunk, with smooth edges; filaments, shorter than the perianth by one-third; anthers, 4 to 6 lines long; ovary, 8 or 9 lines long, a little shorter than the almost straight style; capsule, turbinate, obtuse-angled, 1½ inch long, not umbilicated at the apex; septa, delicate. North Eastern America, from Canada to Georgia. It recedes (along with *L. monadelphum*) from the *Martagon* section towards *Enlirion*, the funnel-shaped perianth, in the expanded flower, being revolute only above the middle.—Var. *penduliflorum*, hort., Leicht., is a form

Canadian Bell-flowered Lily (*L. canadense*).

with segments revolute to or below the middle.—Var. 1, *L. parvum*, Kellogg, Roc. Calif. Acad., ii., t. 52; Regel, Gartenflora, t. 725; Duchartre, Obs. 98.—Bulb and perianth, like those of the type, but in our gardens the plant has a smaller and slenderer habit; stem, green, 1 to 1½ feet high; upper leaves, usually scattered; flowers, much less nodding, sometimes nearly erect; perianth, 15 to 18 lines long, brilliant orange-red, with numerous dots; segments, acute, 3 to 5 lines broad, falcate above the middle; anthers, oblong, 2 or 3 lines long; ovary, 3 or 4 lines long, half the length of the almost straight style. California, on the Sierra Nevada chain, at an altitude of 6,000 feet. Jeffray, 1,283. According to Kellogg, it attains a height of 5 feet, and bears as many as fifty flowers.—Var. 2, *Walkerii*, Wood, Proc. Amer. Acad., 1868, 166.—Stem, 3 feet high, or more; leaves, tender, narrower, arranged in regular whorls of seven or eight leaves, the whorls being very distant from each other; lower leaves, 4 or 5 inches long, 4 or 5 lines broad, the veins very slender in comparison with the mid-rib; flowers, more numerous, arranged in an elongated raceme; perianth, funnel-shaped, 10 to 15 lines long; segments, 2½ to 3 lines broad, falcate only at the apex; stamens, a little shorter than the perianth; anthers, oblong, 1½ line long; ovary, 4 lines long, half the length of the straight

style; stigma, very small. California, Walker, Bridges, 268.—Var. 3. *Parviflorum*, Hook., *Flor. Bor. Am.*, ii., 281; L. Sayii, Nuttall, MSS.; L. canadense var. minus, Wood, *Proc. Acad. Phil.*, 1868, 166.—Stem, 2 or 3 feet high; leaves, in whorls, or most of them scattered; oblanceolate, tender, the lower ones 6 to 12 lines broad; flowers, solitary, or a few in an umbel, nodding; perianth, 18 to 21 lines long; segments, oblanceolate, bluntish, deeply reflexed from the middle, where they are 3 or 4 lines broad; stamens, shorter than the perianth by one-third; anthers, 3 lines long; ovary, 6 lines long, as long as the style. British Columbia and Oregon, Nuttall, Douglas, Lyall, &c. Bulb, like that of L. canadense; perianth, more revolute, but smaller than in L. pardalinum and L. superbum.

26. L. pardalinum.—Kellogg, *Proc. Calif. Acad.*, ii., 12, with a figure; Duchartre, *Obs.* 97.—Bulbs (annual or biennial), shortly rhizomatous; scales, few, lax, lance-shaped, acute; stem, 3 or 4 feet high, terete, green, smooth; leaves, often arranged near the middle of the stem in three or four whorls of nine to twelve leaves, the whorls distant from each other; upper leaves, few, scattered, oblanceolate, of a shining green, 3 or 4 inches long, acute, 9 to 12 lines broad in the middle, smooth, tender; lateral veins, sunk; flowers, three to six in number, arranged in a corymb or lax umbel; pedicels, elongated, nodding at the top; perianth, 2 to 2½ inches long, of a brilliant red, orange at the base; segments, lance-shaped, bluntish, 6 to 9 lines broad in the middle, deeply revolute, the lower half abruptly orange, covered with large purplish-brown spots, and slightly lamellate-papillose; groove, deep, with smooth edges; stamens, shorter than the perianth by one-third; anthers, red, 4 or 5 lines long; style, 12 to 14 lines long, scarcely longer than the ovary; capsule, oblong, umbilicated at the apex, with somewhat acute angles. California, W. Lobb, 249, &c.—Var. 1. *californicum*, hb. Lindley: *Florist*, 1873, t. 33 (by an error the figure there is subscribed "Washingtonianum")—Leaves, fewer, smaller, and in less regular whorls; flowers, one to three in number, longer, 3 or 4 inches long; segments, bluntish, 9 to 12 lines broad, the upper half, as in the type, of a brilliant scarlet, the lower half abruptly orange, with large purplish-brown dots; filaments and style, 1½ to 2 inches long. California, Hartweg. (I have seen the original specimen in Lindley's herbarium, now at Cambridge.)—Var. 2. *pallidifolium*, Baker.—L. *puberulum* hort. Leichtlin, non Torrey.—Taller, in our gardens the stem being 4 or 5 feet high, green and smooth; leaves, 50 to 80 in number, oblanceolate, smooth, pale green, firmer than those of L. pardalinum, distinctly five to seven-nerved, the upper ones usually in regular whorls, the lower ones scattered at the base, at the time of flowering; flowers, if more numerous, in a loose raceme or umbel; pedicels, elongated, nodding at the top; perianth, 2 to 2½ inches long; segments, more acute, 5 or 6 lines broad in the middle, deeply reflexed below the middle, of a paler red on the inner surface than in L. pardalinum, and more tinged with yellow at the base, with fewer and smaller dots; stamens, shorter than the perianth by nearly one-third. California, hort.; Leichtlin.—Var. 3. *Bourgæi*, Baker, differs from *pallidiflorum*, in the few specimens I have seen, by having narrower leaves all arranged in regular whorls, and distinctly three to five-nerved, the veins on the lower part of the inner surface ciliated, and the dots more numerous and larger, after the manner of L. pardalinum. Banks of Lake Winipeg, Bourgeau. Very recently introduced into English gardens.

Superb Orange Lily (*L. superbum*).

27. L. superbum.—L. Sp., 434; Bot. Mag., t. 936; Red. Sil., t. 103; Bury, Hexand., t. 36; Kunth, *Enum.*, iv., 258; *Flore des Serres*, t. 1, 014-15.—Bulbs, large, caespitose, globose, perennial; scales, numerous, acute, closely imbricated, tinged with red; first leaves, firm, glaucous green; stem, 4 to 6 feet high, stout, tinged with purple; leaves often arranged in three or four whorls of eight to ten leaves, few or numerous scattered, narrowly lance-shaped, acute, somewhat firm, of a dull green colour, smooth, distinctly three to five-nerved, the lower ones 4 or 5 inches long, 6 to 9 lines broad in the

middle; flowers, often six to twelve in number, sometimes twenty to forty, arranged in a deltoid panicle 9 to 12 inches broad, pedicels nodding at the top, the lower ones 3 to 5 inches long, divaricated; perianth, 3 or 4 inches long, brilliant orange-red; segments, acute, lance-shaped, 6 to 9 lines broad, deeply revolute, with conspicuous claret-coloured slightly lamellated dots on the lower half; groove, deep, with smooth edges; filaments, 2 to 2½ inches long, very divergent; anthers, reddish, 6 to 7 lines long; ovary, 9 to 12 lines long, a little shorter than the curved style; capsule, obovoid, obtusely six-angled. From Canada to Georgia and Carolina, in woods and marshy places.—Var. L. *carolinianum*, Michx., *Flora*, i., 197; Bot. Mag., t. 2,280; Bot. Reg., t. 580; Kunth, *Enum.*, iv., 258.—L. *Michauxii*, Poir., *Ency.*, iii., 457.—L. *Michauxianum*, Schult. fil., *Syst.*, vii., 258.—L. *autumnale*, Lodd., *Bot. Cab.*, t. 355.—Bulb, exactly like that of the type; first leaves appearing earlier, of a shining green, and thicker; leaves much fewer, broader, and shorter, often five or six in number, arranged in whorls near the middle of the stem, the others scattered; stem, 1 to 2 feet high, bearing one or few heads; perianth, exactly like that of the type, but the segments are sometimes broader and more obtuse. From Virginia and Carolina to Florida, flowering in our gardens in August, among the late-flowering kinds.

28. L. Roezlei.—Regel, *Gartenfl.*, t. 667.—L. canadense, var. *Hartwegii*, Baker, *Gard. Chron.*, 1871, 321.—Bulb, perennial, rhizomatous; stem, 2 or 3 feet high, slender, smooth; leaves, in the specimens I have seen, twenty to thirty in number, a few of the upper or lower ones in whorls, or all scattered, ascending, firm, glaucous, narrowly linear, acute, indistinctly three to five-nerved,

Roez's Orange Lily (*L. Roezlei*).

the lower ones 4 or 5 inches long, 3 or 4 lines broad in the middle; flowers, one to ten in number, if several, in a corymb or raceme; pedicels, elongated, nodding at the top; perianth, 2 or 3 inches long, brilliant orange-red; segments, acuminate, 5 or 6 lines broad in the middle, lower half yellow, with several purple spots, closely reflexed above the base; groove, distinct, with smooth edges; stamens, shorter than the perianth by one-third; anthers, 5 or 6 lines long; style, curved, twice as long as the ovary; I have not seen the capsule. Rocky Mountains in the Utah territory, introduced by Roez

into European gardens. California on the Santa Cruz Mountains, Hartweg, 2,000. Easily distinguished from allied forms, by having narrow acute leaves and perianth segments.

29. L. columbianum.—Hanson in hort., Leicht.—Bulb, ovoid, perennial, small white, acute, with lance-shaped scales; stem, 1½ to 2 feet high, slender, green, smooth; leaves, few, the lower ones in whorls of four or five leaves, the upper ones scattered, oblanceolate, acute, 1½ to 2 inches long, 5 or 6 lines broad in the middle; flowers, two or three in number, in an umbel; pedicels, slender, 2 to 4 inches long, nodding at the top; leaves, reflexed, bracted at the base, sometimes bracteolate; perianth, 1½ to 2 inches long, brilliant orange-red; segments, lance-shaped, closely reflexed from the middle, where they are 4 to 6 lines broad; inner surface covered thickly with purple dots; groove, shallow, smooth; stamens, shorter than the perianth by one-third; anthers, 3 or 4 lines long; style, scarcely longer than the ovary.—Oregon, W. Lobb, 350, hort., Leichtlin. It scarcely differs from L. canadense var. *parviflorum*, except in the bulb not being rhizomatous.

30. L. Humboldtii.—Roezl and Leicht., *Duchartre*, *Obs.* 105; Regel, *Gartenfl.*, t. 724; *Flore des Serres*, t. 1973-4.—L. *Bloomerianum*, hort. Aug.—Bulb, large, 2 to 4 inches in diameter, oblique, perennial, not rhizomatous; scales, few, ovate-lanceolate, acute, 2 or 3 inches long; stem, terete, stout, 4 or 5 feet high, smooth or downy, green, with reddish spots; leaves, usually in four to six regular whorls of ten to fifteen leaves, oblanceolate, the lower ones 4 or 5 inches long, 9 to 12 lines broad above the middle, acute, firm, of a deep green colour, undulated; lateral veins, distinct, sometimes ciliated on the lower part of the inner surface; flowers, often six to ten in number, sometimes thirty to forty, in a deltoid panicle, which is a foot across when fully expanded; pedicels, divaricated, nodding at the top, the lower ones 3 to 5 inches long; leaves, oblanceolate, very much reflexed, bracted; perianth, 3 or 4 inches long, brilliant orange-red, greenish at the base outside; segments, acute, 9 to 12 lines

broad in the middle, closely reflexed above the base, with numerous claret-coloured dots on the inner surface, slightly lamellate-papillose near the base; groove, distinctly excavated, with smooth edges; filaments, $1\frac{1}{2}$ to 2 inches long; anthers, red, 6 to 8 lines long; style, 6 or 7 lines long, about one-third the length of the ovary; capsule large, obovoid, acutely six-angled, as in *L. Martagon*. California, on the Sierra Nevada, Roezl, in hort. Leichtlin.—*L. canadense*, var. *puberulum*, Torrey, Bot. Whipple, 90 (Hartweg 2,004), is a form of this species which has the stem and under-surface of the leaves puberulous.—Var. *ocellatum*, Kellogg, Proc. Calif. Acad., v. 88, t. 4, from the island of Santa Rosa, is a form with a yellow perianth, marked on the inside with conspicuous purple dots.

31. *L. Martagon*.—*L. Sp.*, 435; Jacq., Austr., t. 351; Bot. Mag., t. 893 and 1,634; Red., Lil., t. 146; Eng. Bot., t. 279, edit. 3, t. 1,518; Reich., Ic. Germ., t. 451.—Bulb, ovoid, $1\frac{1}{2}$ to 2 inches long, yellowish, perennial, with very numerous narrow scales; stem, 3 to 6 feet high, terete, smooth or puberulous in the upper part, green or spotted with purple; leaves, mostly in two to four whorls of six to nine leaves, the upper ones (rarely all) scattered, horizontal, oblanceolate, spatulate, sessile, tender, the lower ones 4 to 6 inches long, 12 to 15 lines broad above the middle, tender (with three to five distinct distant veins on each side of the mid-rib), smooth or pubescent; central internodes, 6 to 9 inches long; raceme, lax, elongated,

Humboldt's Orange Lily (*L. Humboldtii*).

Flower-spike of Martagon Lily.

Common Martagon Lily (*L. Martagon*).

containing from three to twenty flowers; bracts, small; pedicels, nodding when bearing flowers, the lowest ones 1 to 3 inches long; perianth, fragrant, claret-coloured, 15 to 18 lines long, pubescent on the ridge outside; segments, lance-shaped, very revolute, with numerous livid purple dots on the inside; claws, slightly lamellated (groove deep, with papillose edges), hooded, thick, and puberulous at the apex; filaments, 8 to 10 lines long, twice the length of the anthers; pollen, red; ovary, 5 or 6 lines long, shorter than the very curved style by one-third; capsule, turbinate, acute-angled, umbilicated at the apex. Central and Southern Europe, to Siberia and Japan, flowering in our gardens at the end of June and beginning of July. For the forms of this species, see Parkinson, Parad., 31.—*L. hirsutum*, Miller, Dict., No. 10 (*L. Milleri*, Schultes, Obs., 67), is a stout form with a puberulous stem.—*L. glabrum*, Spreng, Syst., ii., 62, is a form with white flowers, a smooth stem, shining green leaves, and yellow pollen. There are also forms with claret and flesh-coloured undotted flowers.—Var. *L. Cattanae*, Visiani, Fl. Dalm., Suppl. 32, t. 3.—Segments of the perianth, thicker than in any other species, of a dark, purplish claret colour; dots, nearly obsolete. Dalmatia, Hort., Leichtlin.—*L. Marticum dalmaticum*, Maly, is a similar form, or the same.

32. *L. avenaceum*.—Fischer, Maxim. in Regel, Gartenfl., 1865, 290, t. 485.—*L. Martagon*, Led., Fl. Ross., iv., 149, ex parte.—Bulb, globose, small, perennial; scales, numerous, lance-shaped; stem, smooth, terete, 18 inches to 2 feet high; leaves, usually in a whorl

of six to nine, leaves at the middle of the stem, a few scattered between the whorl and the raceme, seldom in two whorls or all scattered, horizontal, oblanceolate, 3 or 4 inches long, 6 to 18 lines broad above the middle, smooth, tender, similar in texture and venation to those of *L. Martagon*; flowers, few, sometimes sub-umbellate; bracts, small; pedicels, nodding at the top, 2 or 3 inches long; perianth, slightly fragrant, 15 to 18 lines long, of a brilliant yellowish-red; segments, lance-shaped, 4 to 6 lines broad in the middle, hooded at the apex, covered with minute dots on the inside; groove, smooth and deep; filaments, 9 to 12 lines long; anthers, 3 or 4 lines long; ovary, 4 or 5 lines long, half the length of the curved style. Kamtschatka, Manchuria, Kurile Islands, and Japan; Pallas, Maximowicz, &c. It has the habit and foliage of *L. Martagon*, and the yellowish-red perianth of *L. canadensis*.

33. *L. Hansonii*, Leichl.—Bulb, like that of *L. tigrinum*, globose, perennial, compact, whitish; stem, 3 or 4 feet high, slender, smooth, terete, stout, green; leaves, oblanceolate, acute, green, tender, smooth, with three distinct, oblique, tender, distant, lateral nerves, usually collected in a whorl of eight to twelve patent sessile leaves

Bent-styled Lily (*L. avenaceum*).

at the middle of the stem, the others scattered, 4 or 5 inches long, 8 to 12 lines broad above the middle, gradually narrowed from the middle to the base; flowers, four to ten in number, in a loose raceme or crowded into an umbel; pedicels, erect-patent, $1\frac{1}{2}$ to 2 inches long; bracts, small, ovate-lance-shaped; perianth, 15 to 18 lines long, of a brilliant reddish-orange; segments, thick, lance-shaped, 4 or 5 lines broad in the middle, deeply falcate-revolute, dotted with purple on the lower half inside; groove, long, smooth, very deep; filaments, 10 to 12 lines long, yellow; anthers, narrow, 4 or 5 lines long; pollen, yellow; ovary, club-shaped, deeply channelled, 5 or 6 lines long, a little shorter than the style. Japan, hort., Leichtlin; coming into growth and flowering amongst the earliest. This species is midway between *L. Martagon* and *L. canadense*.

34. *L. monadelphum*.—M. Bieb., Flor. Taur., i., 267; Cent. Pl. Ross., t. 4; Gawl. Bot. Mag., t. 1,405; Kunth, Enum., iv., 260; Fisch. & Lall., Ind. Sem. Petrop., 1839, 57; Reich. Exot., t. 89; Regel, Gartenfl., t. 733.—*L. Loddigesianum*, Schultes, fl. Syst. Veg., vii., 416; Kunth, Enum., iv., 261; Lemaire, Jard. Fleur., t. 204; Paxt. Flow. Gard., t. 58.—*L. Szovitsianum*, Fisch. & Lall., Ind. Sem. Petr., 1839, 58; Kunth, Enum., iv., 674; Regel, Gartenfl., t. 436; Flore des Serres, 507.9.—*L. colchicum*, Steven.—Bulb, ovoid, whitish, perennial; scales, numerous, lance-shaped; stem, 2 to 5 feet high, stout, green, puberulous; leaves, thirty to fifty in number, scattered, ascending, linear lance-shaped, or oblanceolate, green, distinctly many-nerved, the central ones 3 or 4 inches long,

Crimson-anthered Lily (*L. Szovitsianum*).

Caucasian Lily (*L. monadelphum*).

6 to 12 lines broad in the middle, pubescent on the back and edges; raceme, usually containing from two to sixteen (sometimes twenty to thirty) flowers; peduncles, $1\frac{1}{2}$ to 2 inches long, nodding at the top; bracts, large, lance-shaped, in pairs; perianth, fragrant, of a sulphur-yellow, $2\frac{1}{2}$ to $3\frac{1}{2}$ inches long; segments, oblanceolate, falcate

above the middle, 9 to 12 lines broad, tinged with purple at the base and apex, and having a few small blackish dots on the inner surface, not papillose; groove, smooth and shallow; filaments, 18 to 21 lines long, green, flattened from the base, valvate at the base of the upper third of their length; anthers, 5 or 6 lines long; pollen, red; ovary, 7 or 8 lines long, half the length of the almost straight style; capsule, obovoid, 18 to 21 lines long, obtuse-angled, umbilicated at the apex. The Caucasus, and northern Persia, flowering in our gardens in June, amongst the earliest. The original plant of Bieberstein is merely a form which has the filaments united below. This species recedes from the others of this group towards *Eulirion*, which it resembles in the form of the perianth, and the absence of papillae, &c. — Var. *L. Ledebourii*, Baker; *L. pyrenaicum*, Led. Fl. Ross, iv., 151, non Gouan. — A dwarfer variety with narrower leaves (80 to 100 in number), linear, seven-nerved, 4 to 6 lines broad in the middle, scarcely pubescent underneath; segments of the perianth, 6 to 8 lines broad. Caucasus, Gildenstadt, C. A. Meyer. (I have seen it growing in Kew Gardens.)

35. *L. polyphyllum*.—D. Don in Royle, Ill. Him. 388; Kunth, Enum. iv., 677; Klotzsch, Reise Wald., 53.—*L. punctatum*, Jacquem. Duchartre, Obs. 76.—Stem, smooth, terete, 2 to 4 feet high; leaves, forty to sixty in number, ascending, scattered (or the lower ones sometimes whorled, according to Jacquemont), green, sessile, acute, smooth, minutely papillose on the edges, resembling those of *L. Martagon* in their texture and venation, the lower ones oblanceolate, 4 or 5 inches long, 6 to 9 lines broad above the middle, the upper ones narrower and linear; peduncle, naked for 5 or 6 inches below the raceme; raceme, lax, containing from four to ten flowers, branches often opposite; bracts, in whorls; pedicels, nodding at the top when bearing flowers, the lower ones 3 to 5 inches long; perianth, 18 to 21 lines long, fragrant, "of a livid-yellow, with claret-coloured dots" (Jacquemont); segments, oblanceolate, 2 or 3 lines broad, revolute from the middle; filaments, 15 to 16 lines long; anthers, 4 lines long; ovary, 6 or 7 lines long, one-third shorter than the very curved style; capsule, obovoid, 12 to 15 lines long, sub-acute-angled. Temperate region of the Western Himalayas (Kunawar, Kashmir, &c.); Royle, Thomson, Jacquemont.

36. *L. ponticum*.—K. Koch, Linnæa xxii., 234; Duchartre, obs. 22.—Bulb, ovoid, an inch in diameter; scales, numerous, lance-shaped; stem, 1½ to 2 feet high, slender, faintly pubescent in the upper part; leaves, 20 to 30 in number, scattered, lance-shaped, firm, ascending, 15 to 18 lines long, 4 to 5 lines broad, the upper one narrower; veins, numerous, distinct; lower part of the inside and the edges pubescent; flowers, 1 to 6 in number, nodding, 18 to 21 lines long, yellow; segments, oblanceolate, reflexed below the middle, where they are 3 or 4 lines broad, scarcely dotted; groove, shallow; filaments, 3 or 4 lines long, half the length of the perianth; ovary, 6 lines long, a little shorter than the club-shaped style; capsule, 1 inch long, obovoid, obtuse-angled. Mountains of Asia Minor, at an altitude of 6,000 to 7,000, K. Koch; the mountainous region of Lazistan, Balansa, Plantes de l'Orient, anno 1866, no. 1,531. It has the leaves and habit of *L. monadelphum*; but is more slender, and the typical perianth of this species is more revolute. Regel's figure (Gartenflora, t. 436), which is referred by K. Koch to *L. ponticum*, in my opinion represents the true *L. Szovitsianum*. In De Candolle's herbarium there is a narrow-leaved specimen from Lazistan, in which the leaves are more crowded, the lower ones 3 inches long, and 3 or 4 lines broad, resembling a variety of *L. monadelphum*.

37. *L. carniolicum*.—Bernh. in Mert and Koch., Deutsch. Flora, ii., 536; Kunth, Enum. iv., 260; Reich. Ic. Flor. Germ., t., 990; Parl. Flor. Ital., ii., 404. — *L. chalcadonicum*, Linn. sp. Plant., 434, ex parte; Jacq. Fl. Austr. Suppl., t., 20; *Martagon pannonicum* sive *exoticum flore spadiceo*, Parkins., Parad., 35.—Bulb, perennial, ovoid; scales numerous, lance-shaped; stem, 2 or 3 feet high, green, puberulous; leaves, thirty or forty in number, scattered, lance-shaped, or linear-lance-shaped, the lower ones 2 or 3 inches long, 6 to 9 lines broad in the middle, flat, distinctly many-nerved, and distinctly ciliated on the margins and the veins of the lower part inside; upper leaves

shorter; pressed close to the peduncle; raceme, few-flowered; pedicels, 2 or 3 inches long, nodding at the top, sometimes bracteolated; perianth, 1½ to 2 inches long, if a brilliant yellow or vermilion; segments, oblanceolate, closely revolute, 5 or 6 lines broad in the middle, with numerous minute dots on the inner surface, papillose downwards; groove distinctly excavated; filaments, 8 to 12 lines long; anthers, 5 or 6 lines long; pollen, saffron; ovary, 5 or 6 lines long, as long as the club-shaped style; capsule, 1½ inches long, obtuse-angled. Lombardy, Istria, Dalmatia, Illyria, and Bosnia; flowering in June.

38. *L. testaceum*.—Lindl. Bot. Reg. 1842, Misc., 51; 1843, t. 11; Paxt. Mag. Bot., 1843, 221, with a figure; Kunth, Enum. iv.,

Buff Lily (*L. testaceum* var. *excelsum*).

Flat-flowered Yellow Lily (*L. testaceum*).

673; Flore des Serres, t., 39; Regel, Gartenfl., t. 349.—*L. excelsum*; Walp. Ann., xi., 110.—*L. isabellinum*, Kunze, in Mohl. and Schlecht., Bot. Zeit., i. 609.—Bulb, globose, perennial; stem, 4 or 5 feet high, slightly downy, tinged with brown; leaves, sixty to a hundred in number, scattered, very close, linear, ascending, firm, dull green, three to five-nerved, the lower ones 3 or 4 inches long, 3 or 4 lines broad in the middle, the margins covered with whitish down, the upper ones gradually smaller, 1 to 1½ inches long, pressed close to the stem, more distinct, being at some distance from the flowers; flowers, three to ten in number, in an umbel or raceme, fragrant; pedicels, erect-patent, 4 to 6 inches long, nodding at the top, bracted with small white-margined leaves; perianth, 2½ to 3 inches long, dull yellow; segments, deeply revolute, 9 to 12 lines broad, with a few small reddish dots near the base, slightly lamellate-papillose; groove, deep, with smooth edges; filaments, half the length of the perianth; anthers, 5 or 6 lines long; pollen, red; ovary, 6 to 8 lines long, about half the length of the curved style. A garden variety, probably a hybrid between *L. candidum* and *L. chalcadonicum*; flowers in the end of July.

Leichtlin Japanese Lily (*L. Leichtlinii*).

39. *L. Leichtlinii*.—Hook., fil., Bot. Mag., t. 5,673; Ill. Hort., t. 540; Flore des Serres, t. 1,736; Belg. Hort., t. 11; Floral Mag., t. 509.—Bulb, small, perennial, globose; scales, few, broad, acute, thick, closely imbricated; stem, 2 or 3 feet high,

of a dark brown colour, slender, faintly covered with down, creeping at the base; leaves, thirty or forty in number, scattered, linear, ascending, of a deep green colour, firm, flat, distinctly three-nerved, the lower ones 3 to 5 inches long, 3 or 4 lines broad, the upper ones lance-shaped and distant from the flowers; flowers, few, in a loose corymb; pedicels, erect-patent, 3 or 4 inches long, nodding at the top; perianth, scentless, 2½ to 3 inches long, of a brilliant lemon colour tinged with purple on the outside, and sprinkled from the base to above the middle on the inside with conspicuous claret-coloured dots; segments, lance-shaped, 6 to 9 lines broad in the middle, deeply

Nodding Red Lily (*L. carniolicum*).

revolute, callous at the apex, channelled, slightly lamellated near the base; groove, deep with faintly pubescent edges; filaments, yellow, 2 to 2½ inches long, diverging widely; anthers, brownish-red, 6 or 7 lines long; ovary, slender, 9 lines long, one-third the length of the curved style. Japan, Maximowicz. It flowers in our gardens in July, at the same time as *L. tigrinum*.—Var. *majus*, Wils. in Journ. Hort., 1873, 371, with a figure, is a luxuriant form, 5 feet high, with leaves 6 or 7 inches long.—*L. Maximowiczii*, Regel, Ind. Sem., Hort. Petr., 1866, 26; Gart, 1868, 322, t. 596; Animad., 1873, 20, is a variety with brilliant scarlet flowers. Japan, Maximowicz.

40. *L. pseudo-tigrinum*.—Carrière, Revue Hort. 1867, 410, with a figure; Regel. Gart. 1868, 118; Animad, 1873, 21.—Bulb, ovoid, perennial; scales, acute, adpressed, moderately thick; stem, 3 or 4 feet high, erect at the base, covered with whitish down, of a lurid green colour, faintly spotted; leaves, scattered, linear, 4 or 5 inches long, 3 or 4 lines broad, recurved-patent, revolute at the edges, when young covered with whitish cobweb-like down on the edges and base outside; raceme, loose, containing four to six flowers; pedicels, erect-patent, 2 or 3 inches long, nodding at the top; bracts and bracteoles, linear; perianth, 2 to 2½ inches long, brilliant scarlet, with numerous dark brown dots on the inside; segments, ovate-lance-shaped, 8 to 12 lines broad above the base, very revolute, and covered with numerous lamellate papillæ; groove, deep; filaments, 2 inches long, scarlet; anthers, 6 or 7 lines long; pollen, red; style, scarlet, 1½ inches long, very much curved, twice as long as the ovary. China. It flowers in our gardens in the beginning of July.

41. *L. pomponium*.—L. Sp., 434; Bot. Mag., t. 271; Kunth, Enum. iv., 266; Reich. Ic. Germ., t. 991; Gren. Fl. France, iii., 181.

Little Turk's Cap Lily (*L. pomponium*). Flower of Little Turk's Cap Lily.

—*L. rubrum*, Lam. and DC., Gall., iii., 213.—Bulb, ovoid, perennial; scales, numerous, lance-shaped; stem, 2 or 3 feet high, thick, straight, channelled; leaves, 100 or more in number, deep green, scattered, narrowly linear, ascending, the lower ones 2 to 4 inches long, 1½ to 2 lines broad, three-nerved, with papillose and slightly revolute margins, the lowest ones 3 or 4 lines broad, the upper ones shorter and narrowly linear; peduncle, bare for 2 or 3 inches below the raceme; raceme, containing from two to fifteen flowers; pedicels, nodding at the top, often bracteolate; perianth, fragrant, 1½ to 2 inches long, usually of a vermilion-red, furnished with numerous papillæ and black dots on the inside; segments, closely revolute, oblanceolate, 3 or 4 lines broad; groove, smooth, distinctly excavated, with smooth edges; filaments, green, 12 to 14 lines long; anthers, 3 or 4 lines long; pollen, vermilion-red; ovary, 5 or 6 lines long, a little shorter than the style; capsule, ovoid, 1½ inches long, umbilicated at the top, somewhat acutely six-angled. Northern Italy and the South of France. It flowers in our gardens in the end of June.—*L. angustifolium*, Mill. Diet., No. 6, is a more slender form, with very narrow one-nerved leaves.—Var. *L. pyrenaicum*, Gouan. Ill. 25; Red. Lil. t. 145; Reich. Ic. Germ., t. 992; Kunth, Enum., iv., 262.—*L. flavum*, Lam. Gall., iii., 283. A more robust variety, with leaves a little broader and distinctly three-nerved, often extending to the base of the raceme; flowers, yellow and larger; bracts larger and style thicker. Pyrenees.—*Martagon luteum non punctatum*, Parkins, Theat., 35, is a variety which has yellow flowers without dots.

42. *L. chalcedonicum*.—Linn. Sp. Plant., 434, ex parte; Gawl. Bot. Mag., t. 993, non Jacq.—*L. rubrum byzantinum* sive *Martagon Constantinopolitanum*, Parkins., Parad., 34.—Bulb, ovoid, perennial,

yellowish; scales, numerous, lance-shaped; stem, straight, downy, 3 or 4 feet high, green tinged with purple; leaves, 100 or more in number, ascending, very close, sessile, pale green, the lowest oblanceolate, the central ones linear, 2 or 3 inches long, 2 or 3 lines broad, three to five-nerved, covered with distinct white papillæ on the edges and on the veins of the lower part inside, upper leaves smaller and pressed close to the peduncle; raceme, few-flowered; pedicels, nodding at the top, often bracteolate; perianth, scentless, 1½ to 2 inches long, usually of a brilliant vermilion-red without dots (but sometimes having a few minute dots on the inside), seldom yellow; segments,

Scarlet Turk's Cap Lily (*L. chalcedonicum*).

ob lanceolate, closely revolute, 5 or 6 lines broad in the middle, with numerous papillæ; groove, distinctly sunk, with smooth edges; filaments, 12 to 14 lines long; anthers, 4 to 4½ lines long; pollen, vermilion-red; ovary, 5 or 6 lines long, about the same length as, or a little shorter than, the style; capsule, obtuse-angled. Greece and the Ionian Islands. It flowers in our gardens in the end of July and beginning of August among the late-blooming kinds.—*L. albanicum*, Griseb. Fl. Rumel., ii., 385; Schur. Transyl., 662.—*L. pyrenaicum*, Baumg. Transyl., 632, non Gouan, from the mountains of Albania and Transylvania, is a variety found in the mountain woods with yellow and usually solitary

flowers.—*L. gracile*, Ebel, Zwölf Tage auf Montenegro, 8, t. 1, from the mountains of Montenegro (flower not described) is a variety which I have not seen.

43. *L. callosum*.—Sieb. et Zucc., Fl. Jap., ix., 86, t. 41; Kunth, Enum., iv., 262; Miquel, Ann. Mus. Lug. Bat., iii., 156.—*L. pomponium*, Thunb., Fl. Jap., 134, non Linn.—Bulb, small, perennial; scales, few, lance-shaped; stem, 1½ to 3 feet high, slender, terete, smooth; leaves, thirty to forty in number, scattered, linear, ascending, smooth, firm, green, three to five-nerved, with narrowly revolute margins; lower leaves, 3 or 4 inches long, 1 to 2 lines broad in the middle, the upper ones becoming gradually smaller; raceme, narrow, lax, containing from two to twelve flowers; pedicels, short, nodding; bracts, in pairs, ligulate, thick, 4 to 9 lines long, obtuse at the apex, and callous; perianth, always of a brilliant scarlet, 12 to 18 lines long; segments, oblanceolate, spatulate, 2½ to 3 lines broad, hooded at the tip, and without dots of any kind on the inner surface; groove, smooth, deep, and with smooth edges; filaments, one-third shorter than the perianth; anthers, scarlet, 3 or 4 lines long; ovary, 5 or 6 lines long, of equal length with the club-shaped, slightly curved style; capsule, obovoid, 15 to 18 lines long, obtuse-angled. Japan and the Loo-choo Islands, Maximowicz, Oldham, 872; Buerger, &c.

Graceful Japanese Lily (*L. callosum*).

smooth; leaves, forty to fifty in number, very narrow, scattered, ascending, the central ones 1½ to 2 feet long and ½ to 1 line broad, one-nerved, and with revolute margins; peduncle, bare for 2 or 3 inches below the raceme; raceme, loose, containing from one to twenty flowers; pedicels, 2 or 3 inches long, nodding at the top; bracts, linear-subulate, in pairs; perianth, 15 to 18 lines long, of a bright pale crimson colour; segments, oblanceolate, 3 or 4 lines broad in the middle, very revolute, usually of one colour, rarely marked with a few small blackish dots; groove, smooth, distinctly sunk; filaments, pale red, 8 or 9 lines long; anthers, twice as long; pollen, scarlet; ovary, 4 to 4½ lines long,

44. *L. tenuifolium*.—Fisch.,

Ind. Sem. Hort. Gorenk., 1812, 8;

Schultes, fil., Syst. Veg., vii.,

409; Kunth, Enum., iv., 263.—

L. punilum, D. C. in Red. Lil.,

t. 378; Kunth, Enum., iv., 263.

—*L. linifolium*, Hornem, Hort.

Hafn., i., 326.—*L. puniceum*,

Sieb. and De Vriese, Ann. Hort.

Pays-Bas, 1861, 23.—Bulb, small,

globose, annual (?); scales, nu-

merous, lance-shaped; stem, 1 to

2 feet high, very slender, terete,

terete,

one-third shorter than the slender style. Siberia, from the Altai Mountains to Amoor-land and Northern China. Pallas, Maximowicz, &c.—Var. *L. stenophyllum*, Baker.—*L. pumilum*, hort. Leichtlin, non DC.—Bulb, more ovoid; scales, fewer and broader; stem, stouter and taller; leaves, distant from each other, $1\frac{1}{2}$ to 2 lines broad, three-nerved; perianth, 18 to 21 lines long; tube, longer and more cylindrical than in the type; segments, narrow and more ligulate. Eastern Siberia, hort. Leichtlin.

Doubtful Species.

45. *L. nanum*.—Klotsch., Reise Wald., 53.—Six inches high, "downy, as far as the base of the leaves, one-flowered; leaves, linear, Grass-like, bluntish, straight, erect, five-nerved; flower, nodding, small, bell-shaped, white; perigonous leaflets, oblong, obtuse, all sessile; stigma, thickened, three-angled, downy; filaments, subulate; anthers, oblong, obtuse, bluntly bifid at the base." Western Himalayas, Hoffmeister.

Slender-leaved Lily (*L. tenuifolium*).

46. *L. lancifolium*.—Thunb. Linn. Trans. ii., 333; Mem. Acad. Petrop. iii., 202, t. 3; Kunth. Enum. iv., 266.—*L. bulbiferum*, Thunb. Jap., 134.—Habit and leaves similar to those of *L. elegans*. Stem, angular, hairy, erect, simple, a foot high or more; leaves, scattered, somewhat distant from each other, ascending, the lower ones linear, and gradually acuminate, 3 or 4 inches long, 5 or 6 lines broad below the middle; the upper ones lance-shaped, becoming gradually shorter, and bearing bulbils in the axils; flowers erect, two in number in the only specimen yet received; pedicels very short, bracted with small ovate leaves. "Corollas" (I doubt whether they were fully developed), "small, unguicular, white." Japan, Thunberg. Described from Thunberg's notes and a figure of the plant kindly sent me by Professor Areschoug. It is probably an imperfectly developed form of *L. elegans*.

[The preceding has been translated for us from Mr. Baker's exhaustive paper on this subject in the "Journal of the Linnean Society."]

GOLDEN APPLES.

GRATITUDE is due to the nameless benefactor who first revealed to a thirsty and luxury-loving West the Orange of commerce; almost the only fruit of Easter Monday. Whoever this personage was, he is an instance of the truth that "the world knows nothing of its greatest men;" for he added to the dessert-tables of Europe a truly golden gift, and set on foot a business which has been justly called of late one of the curiosities of trade. We know pretty well where the Orange first came from. It was almost certainly brought from China by the Portuguese, and there is a garden in Lisbon, attached to one of the palaces, where a gnarled and venerable tree is still shown, said to be the parent stock of all the innumerable Orange orchards of our commonest sort—namely, the *Citrus sinensis*, or *Citrus nobilis*. It was in 1547 that some travelled "Portingall" brought the pips over from which grew that famous plant, and now an enormous area of Southern Europe produces China Oranges. They fill the warmer provinces of the Iberian peninsula with their vegetable gold; they shine all along the sunny nooks of the Riviera; Corsica, Sardinia, Sicily, and South Italy are gilded with them; and all along the north coast of Africa, to Egypt and the Levant, they supply an important crop. The country round Jaffa, in the Holy Land, and again at El Jeneen, in the plain of Esdraelon, is brilliant in winter with the golden globes of this once unknown and unseen fruit, and we import into England alone more than two million bushels. In fact, that which was the fabulous delicacy of the classic world, the "Golden Apples of the Hesperides"—a thing of such beauty and value as to be guarded by dragons, and kept in charge by heavenly nymphs in some hidden garden of an undiscovered Continent—has become, thanks to the Portuguese benefactor and his packet of Chinese pips, a commodity so common that our street Arabs buy at two a penny the prize which it was the eleventh labour

of Hercules to obtain. It is perhaps rather a classical coincidence that the place with which we do the greatest business in Oranges is the group of the Azores, which learned people identify with the fabled Atlantis. During last season there was shipped from St. Michael's and the adjacent islets to British fruit markets no less than 270,000 boxes of the golden fruitage, and many of our swiftest steamers are employed from the time the first crop turns from green to yellow until the last gold is on the trees in racing home with those well-known packages of thin battens which pour their shining contents out in our shops and markets. Give the Orange tree the moist and warm climate which it loves, and keep it from frosts which it cannot stand, and no plant is more bountiful in produce. As many as 20,000 good fruit have been plucked from a single stem at St. Michael's, besides the windfall and unsaleable ones. A good Orange orchard literally grows gold for its possessor. And yet the Orange-loving public knows but few of the many varieties of this popular fruit. Its favourite sort, the Sweet China, is no doubt one of the best, and perhaps it is that which is represented upon the Willow-pattern plate, with the three little men crossing the bridge to pluck the harvest, and the ship waiting to carry it. This variety grows without culture in the Flowery Land, in Nepaul also, and Malaya, and is the kind produced in the Azores. The Orange of the Riviera is a different species, also well known; and the blood-coloured sort, which used to be considered a cross between *Citrus aurantium* and the Pomegranate, is familiar enough, and comes chiefly from Malta. The Mandarin, one of the most delicate and fragrant, which derives its name from being a common present to high officers of state in China, is also freely imported to us. It is one of the finest kinds, and when quite ripe the pulp becomes completely disengaged from the perfumed rind. Then the Seville Bigarade, which makes the marmalade of our breakfast tables, and the Bergamot Orange, from which the perfumers prepare their essences, together with the Shaddock, Pomello, Pompelouses, or forbidden fruit, are all well enough known. But the amateur of Oranges seldom or never sees over here the Pear-shaped variety, or the Fingered kind, where the fruit splits into two or more divisions; or the Phillipine Orange, no bigger than a Gooseberry; or the Horned Bigarade, which has the sweetest of all blossoms; or the Female Bigarade, a most curious kind, where one perfect fruit encloses another; or, again, the Sweet Lemon, called also the Commander's Pear, which is more an Orange than anything else. And if we should pass into the kindred and almost endless kingdom of the Limes, Lemons, Shaddocks, and Citrons, it is astonishing how many varieties might be named of which the British public knows and sees nothing, though many of them would of necessity be most popular. There is no fragrance in all the vegetable world more exquisite than that which is diffused by the Fingered Citron of the Chinese; it is an enormous fruit, with the carpels separated as in the Horned Orange, and genteeler Celestials place it upon a porcelain dish in their apartments, or at their banquets, to delight the nose, for the flavour of the pulp is not very remarkable. Then, if we could only grow the Persian Citron to its proper size in our hothouses, the public would both see one of the loveliest trees in creation, and taste one of the finest sherbets. This plant has rosy, not white, blossoms upon its dark glossy green branches, and is always full at the same time of buds, flowers, and of fruit forming, formed, and ripe. There is no reason why many of these unknown kinds should not be brought over here, except that trade, with all its supposed vivacity and enterprise, is wonderfully conservative. What is liked in the market suffices for shippers; they follow each other like sheep on a path, and lose their money too often in rivalling competitors; while, if they did but introduce a new article, they would start fresh lines of commerce and make fortunes. If the wonderful figures of our British fruit trade could be cited, it would be quickly seen what a mine of wealth may be opened by those who create a new taste in this way among the community. And, while on this subject of the conservatism of the trade in Oranges and Lemons, it cannot be irrelevant to marvel at the abject want of inventiveness and enterprise shown by our merchants as regards new fruits of other tropical sorts. Beyond a feeble experiment now and then with Pomegranates and with the Banana—which is generally either green or rotten—and some of the coarser Nuts, such as monkeys only eat abroad, Covent Garden strikes out no new line. Yet it has comparatively close at hand, in the West Indies, one of the richest fruit-orchards of the globe, overflowing with delicious and wonderful productions which would take the taste of the public by storm. There is the Mango, for instance, which in its perfection, but for a slight flavour of turpentine, would be a fruit almost too dainty for mortal lips; there is the Anona, a ready-made custard, sweetened and perfumed to hand by the subtle cookery of Nature; the Loquat, the Papaw, the Squash, the Avocado Pear, the Bread-fruit, the Guava, the Jack-fruit, and an almost endless catalogue of similar novelties, which are wasted by thousands of tons for want of a

demand. There is, above all, the Mangosteen, a fruit which unites into one divine combination the juiciness of the Alphonse Mango, the perfume of the Bergamot Pear, the sweet solidity of the Nectarine, and the subtle essence of the Pine-apple. The public benefactor who could bring Mangosteens from Malacca would give our frugivorous people an unknown delight, and accumulate profits "beyond the dream of avarice." We shall be told, of course, that the thing is impossible; but the same used to be said about importing fresh beef and mutton from the Antipodes and South America. It used to be thought equally impossible to bring Oranges from St. Michael's, till some sagacious person hit upon the idea of packing them very dry and rather short of ripeness. Apples are carried in large cargoes along with ice from the American ports to Bombay and Calcutta, and no doubt science could find some method of safely transporting the delicious fruit products of tropical gardens to British dessert tables. The problem cannot be insoluble, and, were it solved, not only would the fruit merchants find their trade expanding into greater proportions, but the food stock of these islands would be augmented, and the sunny world of the East and South would become our orchard.—"Telegraph."

ARTIFICIAL BIRDS' NESTS FOR GARDENS AND GROVES.

As in America almost every country dwelling has its martin-house, so in many parts of the Continent, and especially of Germany, no garden or orchard would be complete without one or two nesting boxes

Artificial Bird's-nest.

which may serve either as a home for the starling, or be let unfurnished to more melodious or finer-feathered birds. Occasionally an owl, or a pair of irrepressible chattering sparrows, will take possession of the residence meant for their betters; and then the serious question of eviction arises. In the case of larger grounds, parks, and woods, on the other hand—as, for example, the Bois de Boulogne near Paris, and the Berlin Zoological Gardens, where artificial nests have been distributed for several years past by the hundred thousand—the would-be tenants remain undisturbed, whatever their plumage, voice, or degree of utility. With respect to the employment of hatching-boxes, from the farmer's, forester's, and gardener's point of view, those who have resorted to them abroad are strongly in favour of their adoption in districts much subject to the ravages of grubs, beetles, caterpillars, slugs, &c.; and instances could be quoted in which they have been the means, by attracting and promoting the increase of insectivorous birds, of preserving whole plantations from permanent injury. Recognising their usefulness under the above circumstances, societies for the protection of animals in France, Germany, and Switzerland, award prizes for nests of superior construction and moderate price, and efforts are made to introduce them wherever the feathered population has been unduly diminished, and the balance thus destroyed between the protectors and enemies of vegetation. One of the first to recommend and adopt them with success in England was Waterton, the naturalist; and certainly, if half the complaints one reads of respecting the wholesale capture and slaughter of small birds in different parts of the country are well founded, these aids to bird colonisation are more needed now than even in his time. Apart from all

question of utility, however, the true lover of birds will find any trouble he may take in supplying his garden and grounds with songsters' homes amply repaid by the entertainment and pleasure he will have in observing the habits and movements of his *protégés* during their matrimonial life, and listening to their melodious voices. Concerning the shape and make of the artificial nests; they vary, of course, somewhat, with the kind of bird it is desired to attract. In parts of Switzerland, and especially in the Cantons of Vaud and Neuchâtel, the cylindrical wooden or earthenware nest, represented by fig. 1, has been distributed with very satisfactory results in gardens, plantations, &c., serving as a family mansion for the starling, titmouse, woodpecker, and other birds which build in holes and hollow trees. In

Fig. 2.

Germany, on the other hand, the hexangular varieties, indicated by figs. 2 and 3, are the ones mostly in use, and very "eligible bijou residences" can be constructed of bark, cork, Cocoa-nuts, wired Moss, and Lichen. As a rule, the opening of the nest should face the east, and in deciding on the exact position of the domicile (height from the ground, in bush or tree, &c.), as far as circumstances will allow, regard should be had to the natural habitat of the birds we wish to entice. For the benefit of anyone desirous of giving the nests a trial,

Fig. 3.

we may mention, in conclusion, that specimens of the more approved varieties may be seen at the office of the Society for the Prevention of Cruelty to Animals, 105, Jermyn Street, or purchased of Messrs. Edelsten & Co., of 17, Upper George Street, W. Some of them distributed last spring, in the environs of London, were soon inhabited by starlings, robins, flycatchers, and other birds, and the time has now arrived for a fresh set of tenants.

T. S.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Carrots, Broad Beans, Peas, &c.—Sow the general crop of these now; it is better to postpone sowing the principal supply of them until the present time, for, if they are put in sooner, a considerable portion will often run to seed, more especially in dry seasons, and where the land is light and sandy. For Carrots heavy dressings of fresh manure should be avoided, as this is liable to produce canker; ground that has been well manured for any previous crop, such as Lettuce, Cauliflowers, or Onions, is the best, and if a liberal dressing of soot be worked into the ground it will both increase the weight of the crop, and act as a preventive to disease. Carrots succeed best on land that is neither too heavy, nor too light; but deeply cultivated. An additional supply of Broad Beans and more Peas should now be sown; of the latter, if Champion of England, Veitch's Perfection, and one of the tall kinds, such as Emperor of the Marrows, or British Queen, are all put in at once, a successional crop will be obtained. Unless where the land is wet, Peas at this and subsequent sowings should be sown in shallow trenches, so that the soil covering the seed should be about an inch below the surface level at each side; this will admit of the liberal application of water, which, in dry weather is necessary to them. To further assist them a quantity of manure should be worked in deeply at the bottom of the trenches. Do not sow too thickly; at this and the succeeding sowings half the quantity of seed required earlier, or when there was more to fear from the depredations of slugs and birds, will now suffice. More Spinach should be put in between the rows of Peas or any vacant spaces, and a little more Turnip seed, if required, should also be sown. Of Seakale, if a sufficient quantity of roots is not at hand for planting, seed may now be sown, making holes with a dibber, and covering it with an inch of soil; drop three or four seeds in each hole, which should be 18 inches apart in the row, with a similar space between the rows, these distances asunder being best suited to the proper development of plants of this description. More Cauliflower and Lettuce should be planted out at the present time, giving them a good open situation. The soil must be well prepared, with a liberal application of manure, without which these vegetables can never be had in perfection.

Pits and Frames.—As Cucumbers advance in growth, keep the shoots regulated, training them evenly over the surface of the bed. Pinch off any fruit that appears, until the plants have got sufficient strength to bear without checking their growth. As the roots protrude, add more soil to the hills of earth in which they were planted,

first laying it, for a day or two, up to the sides of the frame, so as to warm it before putting it up to the plants, and maintain the heat by the application of hot dung round the sides of the bed. Sow Vegetable Marrows; these will vegetate quickly in a Cucumber frame, in which they may be kept for a short time, and then gradually hardened off for planting out. The seeds should be sown singly in 48-sized pots, and moved on into larger ones as they require it. Celery plants, as soon as they are large enough to handle, must be pricked out in cold frames. This vegetable likes a rich soil in all stages of its growth, one part of rotten dung to three parts loam being suitable for it; this should be laid 4 inches thick on a bed of ashes, rammed down quite hard, so as not to allow the roots to enter it much. Place an ordinary garden frame upon this, and put in the plants 4 inches apart each way, watering the soil moderately before planting, and never afterwards allow it, during any stage of their growth, to become dry.

Lawns and Pleasure Grounds.—Take advantage of showery weather to have all the walks thoroughly weeded. Small Grasses are the worst to contend with on walks, but where they are removed before they have time to seed—and this they will do whilst very small—they can be kept under with little labour. The use of salt, either applied in a dry state or in the shape of hot brine, is often resorted to for the destruction of weeds on walks, but except in localities near where it is made, it costs more than hand-weeding, and, however applied, its effects are objectionable in causing the surface of the walks to look black and damp. Keep the walks well rolled whilst moist, and an impression can be made upon them. Weeds such as Dandelion and Plantain will now show most objectionably on the Grass, and regular and persistent use of the “spud” is the best method of eradicating them. Some do not dislike to see the common Daisy on their lawns, but nothing looks so well as the Grass alone, and, when these plants exist in numbers not too great to cope with, I advise their being cut out by the roots, for, when the crown of these is destroyed, they do not, like deep-rooted plants, push again so long as they have strength. If Daisies are found even in small numbers, and are not kept down, they quickly increase to a serious extent where a mowing machine is used, for these implements throw the flower-heads over the ground; where, even in an immature state, the seeds will vegetate. A Mossy lawn is liked by some on account of its elastic nature, but the great objection to it is that a dry spell of weather kills it, and gives it a sombre brown hue. There is no better season for destroying Moss than during the April showers; it cannot bear manure, and many kinds, such as super-phosphate, guano, &c., in small quantities, applied as surface-dressings, are recommended for destroying it, but such applications cause the Grass to grow too strong. Newly-slaked lime in a dry powdery state, mixed with an equal quantity of loam, is by far the best remedy. If a dressing of this be applied after mowing, it will destroy the Moss, and will strengthen the Grass without causing it to grow too strong. Care must be taken that the loam with which the lime is mixed is fresh, or it may contain the seeds of weeds; and thus, in removing one evil another might be substituted. Keep the Grass regularly mown. Where a machine is used, there is nothing saved in labour by letting it grow too long before it is cut, as the work is then double. Nothing is more common than to see these machines set too low, so that they cut the Grass in places right down to the very roots, giving the whole a patchy appearance; and, when dry weather comes, these close cut places are almost bare of Grass. The machine should be set so as to avoid this.

Houses. — Vineries. — There are, throughout the country, numbers of amateurs who possess a single Vinery, which in some cases is used for growing various greenhouse plants as well; and the Vines are in fair condition as regards strength, but not as regards fruiting. This often arises from the wood being insufficiently ripened, and is particularly the case in damp northern districts; this state of the wood is not noticed until the leaves begin to turn yellow in the autumn, and the season is too far advanced to remedy the evil. The result is that the following spring little is to be seen besides tendrils, or half-formed bunches that dwindle away. To avoid this, means should be taken to ensure the wood being thoroughly matured. Vines that have been allowed to come on of their own accord will now be breaking, and, to push them on, the house should be closed early in the afternoon, whilst there is yet some hours' sun to fall upon the glass; until they have pushed leaves, the house should be allowed to get moderately warm before air is given in the morning. After they are in leaf, of course, air must be given before the sun has much power on the glass, or scorched leaves will be the result; but all through the season this early closing should be attended to, shutting off the air as soon as the thermometer, properly screened from the direct action of the sun, gets down to 75°, or even to 80° in very hot weather. After so closing the thermometer will often run up to 90°, or considerably more, but no harm need be feared—it will not only

ensure a ripe fruitful condition of the wood for the ensuing year, but benefit the present crop. Even after the fruit begins to colour I should recommend this early closing, giving a little air later on in the evening. Syringe the Vines as the shoots are pushing every afternoon.

TREES AND SHRUBS.

REMARKABLE LIME TREES.

THE common Lime or Linden (*Tilia europæa*) is one of the handsomest and most valuable of our ornamental trees, and its elegant form, luxuriant foliage, and sweet blossoms, render it a conspicuous and attractive object in our parks and pleasure grounds. It has a tall, erect, and rounded trunk, from 50 to 60 feet high, and from 3 to 4 feet in diameter, and the strong erect branches, numerous drooping shoots, and pliant twigs, form a handsome and symmetrical crown. The roots spread for 15 or 20 feet round the tree, and the tap-root penetrates into the ground for 4 or 5 feet. The bark is ash-grey in colour, tough, and smooth, but upon old trees it is sometimes deeply rent and furrowed; the leaves are pale green in colour and somewhat darker upon the upper surface than upon the under; the blossoms, which are hermaphrodite, spring from the upper surface of a bract or leaf-like appendage attached to the peduncle. The leaves appear in May, and the blossoms in June and July; the fruits consist of small, hard, obovate capsules, which ripen towards the end of October and fall off during the early part of winter. Each capsule contains five cells, in each of which is a small brownish seed. The Lime seems to be indigenous to Central Europe, whence it was introduced into this country towards the middle of the sixteenth century. It thrives best in a fresh, rich, black surface soil, with a sub-soil of heavy loam and chalk. If its seeds be sown in November or December young seedlings from them will appear early in the following spring. Besides the common Lime there are several other species, which are chiefly indigenous to the New World. Amongst the best-known European varieties may be mentioned *Tilia grandifolia* and *T. parvifolia*, distinguished principally by the size of their leaves and blossoms. The average age of the Lime is from 600 to 800 years. Its timber is of great value, as it neither warps nor shrinks; it possesses great smoothness and pliancy, and takes a beautiful polish. The beautiful carvings at Windsor Castle, as well as at Trinity College, Cambridge, are made from the wood of the Lime, and the charcoal obtained from it is extensively used in the manufacture of gunpowder; of its inner bark mats are made. In Russia the bark of old Limes is used in roofing houses, and baskets and hampers are prepared from the finer fibres. It is well adapted for hedgerows, as it grows quickly, has a thick foliage, and bears pruning better than almost any other tree. There are several fine Lime trees in various parts of Europe, and especially in Germany. One of the most remarkable of these grows at Neuenstadt, in Würtemberg. The height of this tree is 65 feet, and the circumference of the crown is 96 feet; the trunk, which is 13 feet in diameter at the base, divides—at a height of 8 feet from the ground—into nine huge branches, of which seven are horizontal and two perpendicular. The colossal horizontal branches are supported by 111 pillars; several Gooseberry bushes grow in its crown. The age of this tree is between 800 and 900 years. In 1476 a Lime was planted at Freiburg, in Switzerland, to commemorate the victory of the Swiss at Murten; in 1831 this tree measured 13 feet 9 inches in circumference. In a village near Freiburg there is a Lime tree which was celebrated in 1476 for its great size; in 1831 it measured 36 feet in circumference at a height of 4 feet from the ground; the age of this tree is probably 1,200 years. The annual increase of the diameter of the Lime tree is from $1\frac{3}{4}$ to 2 lines, when the tree is under 300 years old; but, after that age, the average increase is one-third of a line per annum. At Süderheistadt, in Ditmarsh, there is a very old Lime tree, whose colossal branches are bare and leafless, and regarding any buds or leaves since that country was subdued by the Danes. The Germans have long been accustomed to plant Lime trees in the immediate vicinity of their houses, churches, market places, and villages. The Lime tree occasionally

suffers much from the ravages of insects, of which a species of Coccus is one of the worst; it often covers the branches in thousands, and destroys the finest and strongest trees. A species of hawk moth may also be observed early in the summer mornings, or late in the evenings, flitting about Lime trees, and thrusting its proboscis into the flowers; it lays its eggs in July upon the upper leaves, and the young caterpillars appear in fourteen days afterwards, and feed upon the leaves during summer and autumn. It passes the winter in a hole in the earth, and appears in the following May as a perfect moth.

JOHN HUTCHINSON, M.A.

Yew Poisoning.—It is, I believe, a well-known fact, that the virulence of withered Yew branches is far greater than that of the fresh foliage. I recollect seeing some horses that were unfortunately left near a few old lopped off Yew branches, suddenly stagger, drop, and die, three hours after they had eaten the loppings; and I also remember hearing at the time a gentleman, who had lost a valuable carriage-horse through its eating Yew leaves, say the symptoms were not nearly so rapid in his case, and that the surgeon thought that if he had known the cause of the horse's illness when called in, he might probably have saved it. The poison of the Yew tree is said to reside in the leaves, bark, and seeds. The red covering of the fruit is not considered to be injurious; birds feed on its fruit, starlings especially, but I fancy they do not swallow the seeds; or, if they do swallow the entire drupe, the seeds are not broken. I used to notice last season, that birds regularly feasted on the berries of a fine Yew tree, in Liss Churchyard.—HELEN G. WATNEY.

Ivy on Evergreen Trees.—It is an ungrateful task to find fault with any communication from one who provides so much interesting and valuable matter in your columns as Mr. McNab; but in his article upon Ivy (p. 262) there is a statement which must have crept in inadvertently. He says that he cannot call to recollection any instance of Ivy growing on healthy evergreen trees and shrubs (except the Yew), or on any of the Pine tribe. My experience in the moist climate of the west coast, where Ivy is specially luxuriant, proves that this plant is as common upon evergreens as upon other trees; Scotch Fir, Spruce, and Holly, appear as congenial to it as deciduous trees, and it requires constant watchfulness and work to keep it down. I only know of one tree with which it seems unable to cope, and that is the Beech. It grows upon it, but never attains such hurtful proportions as on other trees; moreover, the strong bark of the Beech is proof against the damage which it works on trees with rougher and softer coverings. There is a very beautiful variety of Ivy, with cordate leaves, which has a peculiarly rich effect on walls; I do not know the name under which it is sold, but it resembles no other kind, and cannot be mistaken, from the peculiar shape, large size, and thick substance of its foliage.—SALMONICEPS.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Scale on Ash Trees.—The bark of many of our Ash trees is covered with scale. Is it injurious to the trees, and will it spread?—D. M. [The Ash tree scale sent is *Chionaspis Fraxini*. In many parts of England and Scotland it is very common, and when it attacks a tree it seems to increase in such prodigious numbers as to be beyond all means of human remedy.—A. M.]

Variegated Laurel.—I have recently seen growing at Highfield, on the estate of the Duke of Wellington at Strathfieldsaye, a very true and handsomely variegated form of the common Laurel. The leaves are splashed and mottled creamy-white, with not a single green one amongst them. It has been in the possession of Mr. Davidson, the bailiff, for some years, and he has found it to be perfectly true to character. Good plants of it intermixed with those of the green-leaved kind would be very effective, and as its growth is not so rampant it would, no doubt, make handsome specimen plants. I believe Mr. Davidson will shortly place the stock into the hands of some nurseryman.—A. D.

A Large Araucaria imbricata.—Passing Fawley, in Hampshire, the other day, I was struck with the appearance of a fine specimen of *Araucaria imbricata* about 60 feet high and 15 feet through. The bottom branches have been cut away to the height of 8 feet, and the others droop, so that the tree is as wide at within 10 or 12 feet of the top as at the bottom. There is a fine Juniper about the same height but nearly twice as wide growing within 15 yards of the *Araucaria*, and both look in the most robust health. There was also a good plant of a Bamboo (*B. glauca*) with canes 8 and 9 feet high. This was planted on the bank of an ornamental pond, and appeared to be quite acclimatised.—W. W., *Eaglehurst*.

Golden Spruce Fir.—I have frequently seen, in a neighbouring nursery, a variety of the Fir called the Golden Spruce. It may have been that the stock was affected in some way, or that there were yet no good specimens of it grown, but I confess the gold was not discernible to my eye. A few days since, however, whilst looking over a large number of Spruce Firs near here, I found a veritable golden Spruce—one so strongly marked with the auriferous hue as to make it stand out prominently amongst its fellows. It is also robust and healthy, and bids fair to be constant in its colour. I shall watch its development with interest.—D.

GARDENING FOR THE WEEK.

Kitchen Garden.

THE utility of drawing earth up in a ridge round the stems of vegetables is an operation which has often been called in question; but, like all other customs that have stood the test of years, it has some good points about it. Now, however, when land is so deeply drained, it becomes a question for consideration whether or not some modification of the plan would not in many places be desirable. Experience has taught me that, in light dry soils, it is best not to earth up; but, in that case, deeper planting should be practised, in order to give the plants a firm hold of the soil, without which they would not thrive. All the Cabbage family should be planted in rather deep drills or trenches, which will, in the early stages of growth, facilitate the application of water, when necessary, whilst the frequent use of the hoe amongst the plants gradually increases the amount of soil round the stems, so that ultimately the plants stand as deeply in the ground as if earthed up. I should only recommend earthing up in cold ungenial soils, or in bleak exposed situations; there is, however, no rule without an exception, and this matter must, in the main, be left to the decision of individual cultivators. If not already done, the main crop of Carrots should be sown immediately; the Scarlet Intermediate and Altringham are good kinds for this purpose. Where young small Carrots are required, a bed, in proportion to the demand, of the Early Horn may be sown every five or six weeks during the summer. Finish planting out early Cauliflowers; plant in rows 2 feet apart, in deep drills or trenches; these will now hardly require protection, and will succeed those now advancing under hand-lights and other shelters. Beet may also be sown in most places during the next week, in deep well-worked land. Large roots are not desirable; therefore, too much room should not be given—15 inches between the drills will be ample. The Pine-apple, when true, and Dell's Crimson are perhaps as good kinds as any. A good breadth of Spinach Beet may be sown at the same time; if a dry summer follows, and there is a scarcity of Spinach, properly so called, this will be found valuable. I remember that, during a season of drought, our Spinach ran out, and the man who served the kitchen was instructed to gather the fresh juicy leaves of the Beet, and take them in as Spinach. For a time all went well, and the new Spinach was appreciated; but a word was dropped inadvertently that the new Spinach was the foliage of a Beet, and not a leaf more was allowed to enter the kitchen that season, thus showing how far our prejudices may be carried. The leaves of this Beet are, however, not a bad substitute for Spinach; young leaves of Spinach Beet are, in fact, superior to the inferior Spinach usually produced in very hot parching seasons. Finish Potato planting, as well as the sowing of all main crops of other kinds of vegetables; for, if the weather continues dry, and if a dry hot summer follows, plants established early stand the best chance. Sow Chervil in small quantities once a fortnight or three weeks, and Mustard and Cress weekly, not forgetting the Curled variety of the latter. Lettuces growing in dry warm elevated positions will be better mulched before the moisture is all evaporated from the soil; this will, to some extent, save watering, and at the same time assist growth. All Lettuces should be tied up to blanch, when large enough for that purpose. Wheeler's Tom Thumb Cabbage Lettuce, although small, is very useful, owing to its quick growth and superior flavour, and it is also very hardy—quite as much so, I think, as the brown Cos. In windy exposed places, Peas should have the sticks put to them early, so that, when they throw out tendrils, they may have something to cling to on their upward course. If they once get out of the perpendicular it is very difficult to induce them to take the right course; but timely attention will prevent this.—E. HOBDAV, *Ramsey Abbey*.

Indoor Fruit Department.

Vines.—All the fermenting material which has been employed to create heat on the surface of inside Vine borders may now be cleared off, and the soil forked over. If the roots are close to the surface do not disturb them while performing this operation, but leave the surface rough, so that air and water may penetrate readily. In some instances, watering will not be necessary immediately the soil is forked over, as the dung retains the moisture; sometimes, however, it is necessary to deluge freely and frequently all parts near or under hot-water pipes and flues, to save the roots from perishing from the heat and drought which are liable to affect such places, and much of the fertilising matter which is left on the surface after the dung is taken away is washed down about the roots at the first watering. The borders in which all late Vines are growing must be well watered in time to benefit the young shoots during the early part of their growth. Borders which may not have been watered since the last crop was colouring will be excessively dry now. The first water given sometimes passes down the small fissures without

doing much good, and a second application is necessary a few days afterwards to moisten the whole properly. Vines when efficiently drained suffer more often from want of, than from excessive, watering. Up to the time the laterals cease to grow, and while the berries are swelling, little fear need be entertained of over-watering. After the fruit has set, and until it begins to ripen, a liberal dusting of the best Peruvian guano may be sprinkled over the entire surface before each watering. The damp surface-soil helps greatly to keep the atmosphere moist, but upon hot days it is necessary to sprinkle the pathways two or three times to supply the required humidity.

Pines.—Lose no opportunity of admitting plenty of fresh air about Queen fruit nearly fully swelled. Much larger and finer fruit is obtainable in this way than with confined treatment, and the aid of sun-heat is preferable to that of fire. It is not too late to shift into fruiting-pots, suckers which were not ready when the largest were potted some time back. Old plants, from which the fruit has lately been cut, may be cleared out, to give room to those newly potted, and any suckers which it may be desirable to save should be potted, and must then occupy the place vacated by those shifted into pots of the fruiting size. In all cases it is advisable to turn over and add fresh matter to the plunging material, and newly-potted plants of all kinds require more careful shading now than was needed a few weeks ago. Mats may be laid over the glass during the hottest part of a sunny day, and syringing overhead every afternoon refreshes the foliage. Queens, in particular, are exceedingly fertile in the production of suckers, and sometimes a single plant will throw up a dozen. When it is not intended to increase the stock the whole may be removed but one, and the number left should never exceed three, as it is better to make sure of a small number than run the risk of double the quantity turning out indifferently. In removing the superfluous suckers care must be taken not to injure the foliage or stem of the parent plant. When they cannot be conveniently cut or twisted from the base the point only should be taken out.—J. MUIR.

Hardy Fruit.

The season being so backward, grafting may yet be performed with perfect safety; but the sooner it is done the better. No other kind of fruit varies so much as the Pear, through climate, soil, season, and situation. Of this I never saw a more decided proof than during the past season, for, whilst the fruit of a pyramidal-trained tree of Vicar of Winkfield was quite worthless, except for stewing, the fruit of the same variety trained to a west-wall (growing precisely in the same soil, and not more than a dozen yards from the former) was of the very best quality for dessert. From this it will be seen how difficult it is to give a list of such kinds as are suited to every locality; but for the benefit of those situated as I myself am, that is upon a light sandy soil, I give the names of a dozen kinds which here, at all events, have proved to be the best of the many kinds we grow. The names are appended in the order of ripening, and the season during which they are fit for use is from the end of August to April:—Beurré de l'Assomption, Beurré d'Amanlis, Gansel's Bergamot, Beurré Superfin, Marie Louise, Doyenné du Comice, Durandean or De Tongres, Glou Morceau, Winter Nelis, Beurré Bachelier, Joséphine de Malines, and Bergamotte Esperen. This last kind is by far the best late Pear that has yet come under my observation. Of course, from such a restricted list, very many equally good varieties are excluded. If scions of any of the above kinds are at hand, lose no time in using them to replace those of doubtful quality. Peaches and Nectarines will soon be in flower, when, if the weather proves bad at the time, much care and attention will be required to ensure a successful set. Uncover at all times when the weather is genial, but let the coverings remain down altogether during cold winds or rain. Fly often makes its appearance at this stage, and should be attacked the moment it is perceived, or the consequences may prove disastrous. If taken in time, the best remedy for its destruction is Pooley's Tobacco-powder, which, if dusted thickly over the affected parts twice or thrice in the course of a week, rarely fails to make a complete clearance of the pest for the whole season. So soon as the fruit is set, disbudding must be accomplished; indeed, ought to be done thus early for two reasons; first, because the buds can be much more quickly rubbed off, and, secondly, because it is unreasonable to allow the energies of a tree to be wasted in the production of shoots that are ruthlessly torn off when 4 or 5 inches long. There need be no wonder that gumming and canker are complained of, under these circumstances; a far greater cause for astonishment would be given were trees that have been thus irrationally treated altogether free from these diseases. At this season of the year, when warm borders are in request for early Potatoes, French Beans, &c., the temptation is very strong to encroach on the rights of fruit trees, by planting these vegetables immediately over and about their roots. This practice, although sometimes unavoidable, is much to be reprobated, especially in the matter of Peaches, Nectarines, and

Apricots, as these all require a firm, indeed a hard, border, the digging of which, if well done at first, should not be attempted for years, except when root-pruning is necessary. The manner of feeding the trees I adopt and recommend, is annually to remove the loose inert top soil, using a small hand-fork for the purpose, and carefully working down to the roots; this top-soil is replaced with good maiden loam, with which is incorporated a small quantity of chalk, wood ashes, and a sprinkling of crushed bones. After this is well beaten down, the whole receives a mulching of half-rotted manure, and it is surprising with what rapidity the roots enter this new soil. It is not yet too late to give such a dressing.—W. WILDSMITH, *Heckfield*.

Flower Garden and Pleasure Grounds.

Next to early autumn the present time is the best for transplanting Hollies, Laurels, and other evergreen shrubs; some planters, indeed, prefer the present season to any other for the performance of this operation, which should be carried out as expeditiously as possible, to prevent the roots being long exposed to the sun or to the drying influence of wind. As soon as the plants to be removed have been carefully taken up, let them be at once placed in their new positions and surrounded with sufficient soil to steady them, but avoid treading it in; with the loose soil form a hollow basin around each plant, and into this basin dash several pails of water so as to wash the soil into every crevice, where it will consolidate. Soon after the water has disappeared fill in the remaining soil, and, after a day or two, this may be gently trodden down, and if the plants are likely to be effected by the action of the wind, this should be prevented, as far as possible, by the aid of stakes. After this a mulching of some suitable material should be at once applied to prevent undue evaporation from the moistened soil surrounding the roots of the plants. Showery weather should, if possible, be selected for the performance of this operation; but, should the weather be dry, a good watering overhead with the garden engine on the evenings of bright days will prove very beneficial to the plants, which, if of large size, should have the stem and principal branches bound round with Moss or hay, or soft straw bands, which should be moistened every evening until the plants become somewhat established. This will have the effect of keeping the bark in a moist and healthy condition, facilitate the flow of the sap, &c. It may now, in some instances, be found necessary to supply recently-laid turf with water to prevent it becoming burned up, should the weather continue dry. One of the principal attractions of the pleasure grounds is the beauty of a velvety lawn or greensward, and to secure a close-bottomed turf throughout the season, it is necessary at all times to keep it closely cut, and more particularly so at the present time. Broad-leaved weeds of all kinds, should any make their appearance, should be carefully extracted from it, and before commencing to mow the lawns, &c., they should be well swept, and repeatedly rolled. The latter operation is always most effectually performed soon after a considerable fall of rain. In some instances it may be found advisable to allow the scythe to precede the mowing machine, where the Grass may have been allowed to become somewhat long, and the machine is likely to fail in taking off the long flower-stems or bents. The appearance presented by Ivy-clad deciduous trees during winter is exceedingly picturesque and ornamental, although it is by no means advisable to allow this plant to cling to or to interfere with the development of valuable trees. The case, however, is different with regard to dead or decaying trees, portions of rocks, ruins, &c., which may be clothed and festooned very effectually with this ornamental evergreen plant, and, generally speaking, the more this is left to itself the better it is, but circumstances may sometimes render it desirable to reduce the dimensions or to control the development of such plants to some extent. In cases where brick or stone walls are covered with this plant it is generally desirable to keep it closely cut in, or its increasing weight is apt to force it from the wall. Now is the best time for clipping it close back. This should be done so effectually as not to leave a leaf upon it, and it is surprising to find how soon the wall will again be covered with entirely new and healthy young foliage, which will remain on throughout the season, and the litter from the fall of faded leaves during summer will be avoided. No apprehension need be entertained that the plants will be weakened or injured by this operation, as many instances can be adduced where it has been practised for many years without producing any diminution of vigour in the plants. If it be performed earlier, however, than the present time, there is some risk of the young foliage being injured by late spring frosts. Many of the variegated varieties of the Ivy are very pretty, and may be used with good effect to clothe the stumps of trees, pillars, portions of ruins, &c., if in a somewhat shady situation, or on the north side of a wall; but the plant seldom succeeds so well, nor is the foliage so fine in the full glare of the sun. Large hardy herbaceous plants, such as the various species of Phloxes, Asters, &c., are apt to throw up too many flowering shoots, and these may now be

thinned out. This will have the effect of greatly increasing the strength of the remaining shoots, and will also secure finer heads of bloom. Hardening bedding plants should now be attended to with care. Anything like exposure to cold drying currents of air should be avoided, for they are likely to dry up the tender tissues of plants which have lately been enjoying a warm and moist atmosphere. Many kinds of bedding plants will also, about this time, show a disposition to produce abundance of flowers, and this should be prevented by stopping or pinching back; as, unless the flowers are required, it is inadvisable to allow the plants to exhaust themselves by the production of flowers until they are established in the flower-beds.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Hardy Flowers, Alpine Plants, and the Wild Garden.

The proper time for sowing annuals was, some thirty years ago, a much more important consideration than it is now. Nevertheless, annuals yet have their value, though possibly they do not now stand in the foremost rank. In my young days, the border usually set apart for their culture was of considerable extent; necessarily so, seeing that the collection usually numbered two or three hundred species, containing some good, some indifferent, and many literally worthless, sorts. The predominance of the latter seriously neutralised any good effect produced by the beauty of the former, a result increased rather than diminished by the mode of sowing and culture. Each packet—it mattered not how many hundred, nay thousand, seeds it contained—was circumscribed to a limit of, say, 12 or 15 inches in diameter. Thus, in a space sufficient for three or four plants, hundreds will vegetate, and with what result? None other than the complete annihilation of the true character and development of the plant; its altitude reduced from feet to inches; its blooms, individually small, represented by units instead of hundreds. Circumstances such as these are surely more fitted to illustrate an extreme form of the battle of life among plants than such favourable cultural conditions as should assist, rather than retard, Nature in the fulfilment of her operations. Such, however, has been, and still is, the way too frequently followed in dealing with annuals. It is true, some of the more prominent among them, such as Stocks, Asters, and Marigolds, are even now deemed worthy of an individuality of growth, and a sufficiency of space, wherein to develop themselves. But there are others equally pretty whose claims have been hitherto wholly ignored. To those who will persist in sowing annuals, as I have before described, I would say pull up all, except, say, five plants, or tufts, if thinning-out to single plants be too much trouble. In the latter case, when reduced to such close quarters, they will fight the battle out among themselves, and one, or perhaps two, will represent the victors in the strife. My advice, however, is to raise annuals in shallow boxes, under shelter of a frame where tender, or quite exposed where hardy; and from these boxes the various little groups can be transferred to the border by dibbling them in; selecting, of course, a day immediately succeeding a good fall of rain for the purpose. In all herbaceous borders, it matters not how careful the management may be, blanks are sure to occur, originating from various causes, to which I need not here allude. Where bulbs, the majority of which are spring-blooming plants, have a special section of the garden allotted to their culture, an admirable opportunity presents itself for growing annuals, whereby, in addition to the spring flowers, a summer and autumn display may be secured to this otherwise naked portion of the garden. Here I would recommend sectioning the seeds out into, say, three divisions, as regards height, viz., dwarf, medium, and tall, mixing the various elements of each section together, and sowing the several mixtures now broadcast on the rough ground, having regard in respect of height to the gradation from the margin to the centre of each bed. By this means an agreeable mixture—both in colour and habit of growth—is secured, and a fair sprinkling of Mignonette adds its neutral tint. The same plan may be adopted with recently-planted shrubberies wherever there are spaces of bare earth between the shrubs. Such annuals as Collinsias, Nemophilas, Limnanthes, &c., are never seen to such advantage as, when self-sown in the autumn, they survive the winter, and burst into rich and brilliant blossom early in May. While the ground is yet cool, and the influence of the April showers has not yet disappeared, they present a brilliancy in colour, and a rich depth of green in foliage that is rarely ever attained under the scorching suns of July and August. To the list of annuals given by Mr. Grieve at page 290 let me add the fine old Love-lies-bleeding and Prince's Feather, Virginian Stock, Limnanthes Douglasii, Collinsias of all kinds, Clarkias, Eucharidiums, the charming little early-blooming Ionopsidium acaule, Convolvulus minor, Nemophilas, from the azure blue insignis to the almost black discoidalis, Leptosiphons, and the various forms and colours of Candytuft, nor are some of the double Sunflowers to be despised, as they are well adapted for the back ranks amongst shrubberies. The old Malope

and Hibiscus Trionum, Malva zebrina and crispa, the latter contributing in its crimp-edged leaves, a useful accessory towards the decoration of the dessert table.—JAS. C. NIVEN, *Botanic Garden, Hull.*

SETTING BOILERS ABOVE THE PIPES.

THOSE who have written in approval of boilers being set higher than the pipes, speak of the matter as if it were something new, which is anything but the case; for there are numbers of boilers to be found in the country set in that way. Many years ago I had one under my own care, and I have known others so placed, all of which varied considerably in the manner in which they did their work. Whilst a boiler so set is under-worked, say with not more than one-half or two-thirds of the piping attached to it that it should have, it can often be made to work properly, but it is always by the consumption of more fuel than if it were placed below its work. Moreover, where a boiler is so fixed, another and still greater evil generally arises affecting both the labour in attention and the consumption of fuel: it is this—the water in the piping of some of the houses to be heated will circulate at a reasonable temperature, whilst in others it will not move unless very hot, consequently, for these latter, it becomes necessary to keep the water much hotter than otherwise would be required—a circumstance that needs little comment as to the way in which it affects both the labour and fuel account in the course of the year. And those who risk setting a boiler in this way, where there is a number of houses to be heated by it, must not imagine that they are certain to get off with only the drawbacks just named. There are no more powerful boilers extant than the large upright tubular ones; the sole objection to them is their liability to break down, and the extravagant amount of fuel they consume. If any boiler can be made to force the water to flow in a direction in which it is not disposed to circulate, they will do it; yet I well recollect a friend of mine putting in a large boiler of this description to heat a moderate number of small houses, which only half the boiler, if properly placed, would have worked with ease. It was placed some 12 or 15 inches above its work, that is, the flow-pipe from the top dipped so much before it entered the houses, with sufficient size afterwards. It had a 4-inch expansion pipe 12 feet in height, and was set under the superintendence of a man sent down for the purpose, yet the water would not enter a single house, although every day for a week it was made so hot as to boil over the expansion pipe and to threaten to empty the apparatus. Additional air pipes were put in under the impression that there was a stoppage by air, and the pipes at the highest and most distant point from the boiler were considerably raised; but all was useless. After every other expedient had been tried without avail, the boiler was lowered 18 inches, after which no difficulty was experienced in getting it to work. Of this I was a witness, and it convinced me that there was no certainty of a boiler acting when placed above its work. Anyone who can discover a means by which the natural laws that govern the circulation of heated fluids can be reversed, may place his boiler where he likes—as high as the top of the house, if he chooses—with a prospect of its succeeding; but, until then, I hold, to have them right, boilers must be set below the flow pipe. Next to a boiler being placed high, dips and sudden rises, with corresponding depressions, such as going under and over doorways, are objectionable, and should always, if possible, be avoided, which they generally can be if sufficient forethought be exercised in planning the work; for where these exist, even when the apparatus can be made to act, it is always at an increased expenditure of fuel, in addition to which they generally interfere with the circulation often in some other house attached to the boiler. Stokeholes, with an accumulation of water in them, are certainly objectionable, but there is no reason why these should exist. Three-fourths the cost of excluding the water from such is generally expended in half measures, and often fruitlessly, whereas, if the right means were taken at first, the water could be excluded effectually at half the expense incurred. In connection with boilers in general, this winter's frost, although short, was sufficiently severe to explode many a cherished hope as to the sufficiency of numbers of boilers that have not previously been put to the test of a cold winter. I have received as many communications as would half fill a number of THE GARDEN on the subject of break-downs and inefficiency to perform the work required. If a third of the numerous disappointments experienced, and injury done during that short week's frost, were generally known, one-half of the contrivances, in the shape of boilers, would soon find their place amongst old iron.

T. BAINES.

Heat in Turfed and Unturfed Ground.—It has been ascertained (says the "Contes Rendus") that the temperature below the soil, when the surface has been stripped, in frosty weather is much lower than when it is covered with turf.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 7.

ON this occasion several plants of more than ordinary interest were exhibited. Messrs. Veitch & Sons furnished a collection of *Droseras*, *Sarracenias*, *Darlingtonias*, *Cephalotus*, and other curiosities, which attracted much attention; also *Dracæna Hendersonii*, a robust variety, having broad and gracefully recurved foliage, of a pale green colour, striped with rosy-carmine, dark green, and white irregular lines; *Croton tortile*, with corkscrew-like foliage of a deep glossy green, edged and mottled with crimson; *Exacum zeylanicum*, a dwarf six-blue-flowered plant, with opposite glossy green ovate cordate leaves; *Hyacinth Mount Etna*, a semi-double deep rosy kind; *Croton appendiculatum*, a kind with singular-looking deep green leaves; *Spathiphyllum Wallisii*, a white-flowered caulescent *Arad*, with lanceolate deep green foliage, and large creamy-white bowl-shaped spathes; and *Anthurium violaceum*, a creeping *Arad*, with deep green glossy leaves, and oblong clusters of purplish berries—a plant well worth a place on the back wall of a warm moist stove. The same firm also showed a new *Croton*, alluded to below. Mr. B. S. Williams furnished a well-grown collection of new and rare Ferns, Orchids, and Palms, including the elegant *Geonoma gracilis*, which promises to rival the now well known *Cocos Weddelliana* itself; also a good plant of *Martinezia erosa*, and a new Fern, of robust appearance and distinct habit, named *Pteris Williamsii*, but otherwise known in gardens as *Gymnogramma japonica*. It has five-lobed fronds, of a deep green tint, the pinnæ being finely serrulate along their margins of a deep cream colour, mottled or feathered along on each side the mid-rib with pale green. In the same collection were also *Warszewiczella discolor*, with four white-sepalled rich purple-lipped flowers; *Eurycles Cunninghamii*, a beautiful Australian bulb, with foliage like that of a *Eucharis*, but distinctly netted with dark veins, and flowers about the size and substance of a *Tuberose*, and in shape similar to those of a small *Eucharis*. Mr. W. Bull had a white variegated *Dracæna*, named *D. candida*, which is distinct, and ought to become a favourite for table decoration, also *D. insignis*, a deep bronze-purple-leaved variety, margined with crimson; a plant of the white variety of *Odontoglossum Roezlii*, which differs from the normal form in being devoid of purple markings on the petals; a strong plant of *Crinum brachynema*, bearing two tall spikes of drooping, white, bell-shaped, long-tubed flowers. Messrs. G. Paul & Sons exhibited a stand of cut Roses, among which were flowers of *Cheshunt Hybrid*, rosy-purple; *Duke of Edinburgh*, crimson; *Captain Christy*, blush; *Annie Laxton*, bright rose; and the ever-welcome *Etienne Levet*, a fine round smooth-petalled rosy-purple variety. Messrs. Paul also staged the new Hybrid Perpetual *Hyppolyte Jamain*, a large full Rose, of a rosy-lilac colour, flushed with crimson in the centre. Mr. R. Dean furnished a beautiful group of early-flowering *Forget-me-nots*, *Primroses*, and *Polyanthus*. A large potful of the violet-flowered *Aubrietia Eyreii* also came from the same exhibitor, who sent among the *Primroses* a deep crimson variety, named *Crimson Queen*. Mr. Dean also exhibited a new *Golden Spruce*, with yellowish foliage. Mr. H. Eckford, *Coleshill*, sent examples of a robust rosy-purple-flowered Chinese *Primula*, named *Emily Maria*; also flowers of white, lilac, and rosy varieties of Chinese *Primula*, and a stand of dark brownish-crimson Gold-laced *Polyanthuses*. Mr. J. Perkins, the Gardens, *Thornham Hall*, *Suffolk*, contributed a stand of the yellow *Tea Rose Maréchal Niel*, in excellent condition; and four well-grown spiral-shaped plants of *Clematis montana* came from the Society's gardens at *Chiswick*. A fine plant of *Dendrobium nobile*, about 3 feet in diameter, and profusely bloomed, came from Mr. F. Moore, gardener to Mr. W. C. Pickersgill, *Blendon Hall*, *Bexley*; it was a good specimen of skilful culture, and deservedly obtained a cultural certificate. Mr. J. Staples, gardener to Mrs. Candy, *Sevenoaks*, sent a fine plant of *Dendrobium densiflorum*, bearing twenty-eight spikes of deep golden-yellow flowers, the foliage being very fresh and healthy.

First Class Certificates were awarded to the following new or rare plants:—

Hyacinth Etna (Veitch).—This is a showy semi-double bright rosy variety, which will prove an acquisition. Its spike is well furnished with bloom, and the foliage is stout and of that bright green wax-like tint so much admired by *Hyacinth* growers for exhibition.

Croton Disraeli (Veitch).—This is a very distinct form, robust in habit and having curious halberd or javelin-shaped deep green leaves blotched and spotted with golden-yellow.

Geonoma gracilis (Williams).—This is one of the most graceful of all Palms, having elegantly recurved, slender, pinnate foliage of a bright green tint; as a decorative plant it will prove a rival to the now well-known *Cocos Weddelliana*.

Martinezia erosa (Williams).—This is another Palm belonging to the pinnate-leaved group, and resembling a *Wallichia* in general contour. Its arching, densely spinose petioles bear erosely cut or jagged pinnæ of a pale green hue, inclined to glaucous. It will form a worthy companion to the more sturdy habited *M. caryotefolia*.

Dracæna candida (Bull).—This belongs to the *D. Regina* group, but is much dwarfer in habit, and its elegant lance-shaped foliage becomes well coloured in a young state. As a stove decorative plant, or as a dinner-table ornament, this *Dracæna* cannot fail to occupy a prominent place.

Dracæna insignis (Bull).—This is similar to the last as regards dwarfness of habit and slender foliage; but the colour of the leaves is deep purple, with irregular crimson-tinted margins.

Crinum brachynema (Bull).—This is a strong-growing Indian bulb, which bears from eight to twelve drooping, white, long-tufted, bell-shaped flowers, on naked scapes from 2 to 3 feet in height. It is evidently a profuse bloomer, and is well worth culture for the sake of its snowy deliciously-fragrant flowers, which will associate well with those of the *Eucharis*.

Drosera spatulata (Veitch).—This is a pretty little rosette-shaped Sundew, with longer leaves than our native *D. rotundifolia*, and densely set with crimson or ruby-tinted viscous glands.

NOTES AND QUESTIONS—VARIOUS.

Triteleia laxa and *Murrayana* (see p. 255).—Some think that these are the same species, but that *Murrayana* is a dwarfer form than *laxa*.—J. B.

Asplenium Trichomanes incisum Claphami.—Can any of your readers tell me where this variety of *Spleenwort* can be procured?—R. N.

Macadamia ternifolia.—Is this hardy? It is said to bear a nut, but two plants of it, which for some time have been kept in a conservatory here, show no signs of fruit.—K.

Sulham Prize Celery.—I have this year grown many varieties of *Celery*, but I give the palm to *Sulham Prize*; it is not particularly large, but solid and crisp; keeps well, and is altogether a really true stock of a good variety.—R. GILBERT, *Burghley*.

Wardie Lodge Variegated Kale.—Notwithstanding the severe winter that we have had, this *Kale* has become an object of beauty in the flower garden and its leaves and sprouts look pretty used for room decoration along with *Croci*, *Narcissi*, and other spring flowers.—WILLIAM LAURIE, *Lynnwood, Alva*.

Deutzia crenata flore pleno.—This favourite plant is forced in large quantities by Mr. Hayes, of *Edmonton*, and the flowers are, and have been for some time, very beautiful. They do not, as in the open air, assume a pink tinge, but are pure white, and the pearl-like buds are as attractive as the open flowers.—R.

Viburnum macrocephalum.—The plant figured last week (see p. 287) as *Viburnum Keteleeri* is simply the wild normal form of the monstrous and better known *Viburnum macrocephalum*, a favourite in our gardens. This plant is used by the Chinese as a stock for the more admired sterile form.—GEORGE GORDON, *A.L.S.*

Daisy Destroyers.—Little grubs have attacked and destroyed nearly the whole of the foliage of my French *Daisies*. What are they, and what would be the best means of getting rid of them?—E. L. [*Julus pulchellus* is the name of the culprit—one of the smallest and most beautiful of the "snake-millipeds." It is so small that it is difficult to deal with; still something may be done to diminish its numbers by laying traps of slices of *Potato*, under which they gather, and can then be destroyed.—A.M.]

Green Double Cinerarias.—It would appear that double varieties of this plant cannot be perpetuated true from seed, and that an error of rather a serious character was made when it was asserted that such could be accomplished. The flowers produced from seeds in many cases bear no resemblance whatever to the double *Cineraria*, of which so many illustrations have been given, but are of a plethoric nature, and of a dingy green colour far from ornamental.—GEO. WESTLAND, *Witley Court, Stourport*.

Fruiting of Quercus glabra.—Allow me to inform your correspondent "K." that a noble plant of this fine-leaved *Oak* at *Bicton* produced acorns sixteen or seventeen years ago, and has annually furnished fruit ever since, in bunches or clusters of from three to eight or ten on a stalk, in the same way as common *Nuts* or *Filberts*; owing, however, to the male catkins being produced as early as the month of February, when they get injured by spring frosts and cutting winds, the acorns are not often very perfectly formed in exposed situations.—JAMES BARNES.

Sedum amplexicaule Unsuitable for Carpet-bedding.—Your correspondent "D" (p. 280) recommends *Sedum amplexicaule* as "a charming variety for carpet bedding." It is a very curious and interesting plant, and does well on rock-work, but is not at all suited for carpet bedding. In the summer the whole plant collapses, and looks just like a collection of little dried brown sticks, a state in which it remains until the occurrence of autumn rains, when it again shoots out its pale green foliage, and is a pretty plant during the winter.—H. N. ELLACOMBE, *Bitton Vicarage*.

A Small Portable Hotbed.—A gentle bottom heat, and the genial humidity which attends it, are of manifest advantage in hastening and facilitating the germination of many kinds of seeds. A large hotbed and frame are not at everyone's service when wanted for this purpose. A box with a quantity of sawdust or any other plunging material placed in the bottom of it to plunge the pots in, makes a good hotbed when set on the top of a flow-pipe in any hot-house. A large number of small pots may be got into a 2-feet square box, and the whole may be formed or shifted with the greatest ease. The mouth of the box should be covered over with a pane of glass to keep in the heat and moisture.—M.

Pruning Camellias.—The beneficial effects of pruning *Camellias* have been clearly shown here in the case of a large bush of the old double-striped variety. The first flowers on the plant were cut at the latter end of last September, and there are still a dozen or two of blooms on it that are either open or opening; its period of flowering has thus extended over six months. This is not an exceptional circumstance with this plant, for the same thing has happened year after year. The secret lies in the plant being turned out; in its being grown in sandy loamy soil; in plenty of diluted dung-water being given to it through the flowering, but not through the growing, period; and, lastly, in its being frequently pruned.—CHEVALIER.

Moving Evergreen Trees.—I have occasion from time to time to move, as they encroach on each other, various ornamental trees and shrubs; and I have found great difficulty in effecting this successfully with one or two species, notably the *Hemlock Spruce* and the *Evergreen Oak*. I have now several specimens of both these trees, of from 12 to 18 feet high, which need removal; and I shall be glad to learn from those of greater experience than myself how best to deal with them, especially as regards proper season, or subsequent treatment. The trees to be moved are usually dug round some time previously to removal, and are transported on an iron plate inserted under them, so as to secure a pretty good ball. Neither *Wellingtonias* nor *Deodars* move well; but do not fail in any such degree as those which I have mentioned.—HANTS.

Vegetables in the Midland Counties.—*Broccoli* with us is scarce, the long and sharp winter having injured it considerably. We have, however, been cutting *Snow's* all winter, and to-day (April 4th) we cut some good heads of *Watt's Excelsior*. *Barr's Criterion* has stood best with us; but it is late. *Peas* never looked better. I have *Racehorse* running 9 inches high. *William the First* is decidedly the hardiest of all *Peas* here. *Standard*, another of Mr. *Laxton's* *Peas*, is also looking well, but dwarf. All were sown on the 9th of November; succession crops are coming up well, and look promising. Of *Cabbage*, we shall cut *Barr's A 1* next week, on warm south borders, where it has been netted all winter; while the *Cabbage* quarter, properly so called, is bare, occasioned by the pheasants and pigeons pecking the outside leaves off. A good hoeing has, however, made the plants start afresh. *Asparagus* is just making its appearance, and to-day I noticed a few *Potatoes* pushing above ground, while spring-sown *Spinach* and *Turnips* are all up and flourishing. With a warm shower or two, and a little sunshine, all will soon look green, fresh, and spring-like.—R. GILBERT, *Burghley*.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

STAMPED LEAD OR ZINC LABELS.

IN THE GARDEN of the 27th March, "Salmoniceps" makes some excellent remarks on the importance of using good and durable labels for marking the names of plants, and describes the form of label which he considers the most perfect. I am induced by his remarks to say a few words in favour of stamped lead or zinc labels, which appear to me to be very little known, and not half sufficiently appreciated. Every one who grows a mixed collection of plants must have often felt the annoyance of striving in vain to decipher the name of some once well known plant on a half-rotten label. The labels which I use are made of common sheet lead, which I obtain second-hand, and cut into strips, usually 6 inches long, by five-eighths wide, a size which suits well for pot plants, and also for Roses, fruit trees, and shrubs. For herbaceous plants in borders I cut them $7\frac{1}{2}$ inches long, by seven-eighths of an-inch wide. The labels are pointed at one end, and the corners bevelled off at the other. The names are stamped with ordinary steel punches, which cost about 10s. 6d. per set of twenty-six letters. The letters I use are a little over one-eighth of an-inch in height, which I consider the best size for ordinary use; but if they are required to be read at a distance they would have to be larger. When the name is punched, a little white lead paint is smeared over it, and is at once wiped off with a cloth, which leaves the letters clearly marked out in white on a lead-coloured ground; if a little chrome-yellow be mixed with the paint it gives the writing a pleasing buff colour; white does not show well on zinc. These labels are simply thrust into the soil of the pot or the border, according to their size, and are very quiet and unobtrusive in their appearance, and extremely permanent. For Roses, fruit trees, and shrubs, the label is wound round the stem or one of the branches in the form of a ring. As the branch grows the label expands with it, and after many years, when the tree has become too large the label is uncoiled and placed on another branch, and will thus outlive the tree itself. If nurserymen were once to take to the system of sending out such labels, charging a small extra price for plants so labelled, I am sure they would soon come into universal demand. I have also used labels similar in form to those figured by "Salmoniceps," viz., oval labels soldered in a slanting position on the top of a stout galvanised iron wire 2 feet long, and find them practically indestructible; but, as they require soldering or rivetting after they are punched, they are better fitted for botanical gardens than for private use. I have also used them suspended by lead wire, but the constant movement of the wind infallibly saws the label through and allows it to drop to the ground. Although I have hitherto made these labels by cutting the lead with shears, I am now having them stamped out by a lever hand-punch. I have also two alphabets, one being a small one for trivial notes and dates. Annexed is a figure of

the little machine I use for stamping; it consists of two plates of iron hinged together at the back; the bottom forms a stout bed plate, and is screwed to a board; the top plate has a slot cut in it as shown in the drawing, with bevelled edges. This slot is $4\frac{1}{2}$ inches long, and seven-sixteenths wide, and the top and bottom edges guide the punches for two-rows of letters; the front edge of the upper plate is also bevelled and serves

as a guide for broader labels. The two plates are pressed open by a spring, and the label, when inserted, is gripped by a hand-screw on the top; there are also guide-pins between the plates to adjust the label to its position. The punches are arranged at the back in two ranks, being dropped into holes, and each punch is lettered on its front face. I have punches for U S, U M, and note of interrogation. The stand is about 8 inches broad and 10 inches deep, and in my case can be screwed on the top of a tripod stand, so that the whole can be carried about the garden. The writing can be effected with great rapidity after a little practice. I have sometimes employed zinc labels instead of lead, and they seem nearly as permanent, but require a much heavier blow to imprint them. The weight of the larger label is nearly 4 oz., and of the smaller about 2 oz. The zinc ones are, of course, lighter and cheaper. "Salmoniceps" characterises the necessary qualities of a good label to be durability, legibility, unobtrusiveness, and cheapness. As regards the first three requirements, these labels defy competition. I have seen lead labels which have been nailed against a wall behind fruit trees for fifty years, and I have quantities which have been stuck in pots and lost sight of in borders for fifteen years, and in every case they appear as good as those made yesterday. At the Oxford Botanic Gardens these labels are in partial use, and the experience of them there is the same as my own. Their appearance is particularly quiet, and they are very legible, even after years of exposure. They have not the merit of cheapness in first cost, and in quantity they are inconveniently heavy to handle; but as I only advocate them for permanent plants and shrubs, and as the old material retains its original value, these to many would not be serious objections. Each label may be used twice by painting out the old name, and reversing the sides. The zinc labels are very much cheaper and lighter, and may be bought in suitable sizes ready made; but, on the whole, I prefer lead. I have myself derived the greatest satisfaction from their use, and I must venture to repeat that if nurserymen would supply such labels with trees and plants when specially ordered, they would confer a great boon on the amateur horticulturist. I believe also it would answer their purpose to sell the machines and stamps for making labels, and also the labels themselves, both in blank, and with names punched to order. While on this subject, I cannot help saying that I find it very convenient to put white or yellow paint into the collapsible metallic capsules used by artists, which I buy of Lechertier Barbe, Regent Street. A small quantity is squeezed out when making a label; and, as there is no waste, they are both convenient and economical.

LATIMER CLARK.

Hitherwood, Sydenham Hill.

FORCING EARLY GRAPES.

WE have had few sunny days here since Christmas. Our first and second Vineries were, during the third week in October, all washed with hot lime as soon as slaked. If a handful of sulphur be thrown into the lime-wash, and plenty of turpentine is mixed with the paint, this mixture will destroy all kinds of insects with which it comes in contact. Cleanliness is a matter of the first importance in forcing houses; and prevention being always better than cure, any trouble taken in thoroughly painting every crevice will not be thrown away. When the work is finished turn on the water for a day, with plenty of air, so as to thoroughly dry and harden the application before closing the house. We shut up our first and second Vineries the first week in November, syringing the Vines twice a day, and keeping the house as moist as possible till the buds show green, and then the use of the syringe may be dispensed with for the season, for the bloom always looks faded where the syringe has been used on the fruit, even if the water be as clear as crystal. The outside borders are all covered with 10 to 12 inches of litter, and wooden shutters are placed on the top to keep out rain and frost, and we never remove either the litter or the shutters till the Grapes are ripe. The inside borders are raked over and left rough on the surface, and then we put about an inch or so of fresh rotten manure on the top, which serves as a protection to the top roots. Watering will carry the manurial properties of this mulching down to the roots by degrees, and keep the surface of

the soil in a genial moist condition, besides attracting the young roots to the surface, which give colour and substance to fruit and foliage. We commence to give fire-heat about the 20th November, to the extent of 55° to 60° at night, and 5° higher in daytime, till the buds begin to swell; the night temperature is then raised to 60° , and the day temperature to 65° . This is continued till the bunches get fairly visible, when another slight increase of heat is given, till, by the time they come into bloom, the night temperature is 65° , and day 70° . We never, on any occasion, go higher than this with fire-heat alone; but we never move a ventilator from the time the houses are closed till the fruit is half coloured, and then the first mild day the front ventilators are opened a little, as often as the weather will permit, which gives motion to the inside atmosphere, whilst both the heat and moisture are retained; on the other hand, if the top ventilators were opened, the heat and moisture would escape, which would render it necessary to keep the pipes hot, and this would create a dry parching atmosphere that always checks growth and renders the leaves liable to attacks from red spider; in fact, drought in any kind of forcing should be guarded against, although extreme moisture should also be avoided. On a dull, dark day, keep the temperature low and the house quiet; but on a bright, clear day, work it up to 85° or to 90° . Treated in this way, Vines will always produce a clean expanded foliage, possessing plenty of substance with which to finish off the fruit satisfactorily. Our first house was in full bloom the first week in January, and, while they continued so, no difference was made in the temperature, excepting in the morning, when no more moisture than is absolutely necessary should be given till ten o'clock; when the canes are gently tapped, to put the pollen into motion, and then any part that requires it is moistened. A great deal, however, depends on the weather outside—if dark and dull, little moisture is required; but if bright and clear you may give a larger quantity. There is a great deal more harm done, as regards bad setting, with a dry, parched atmosphere and plenty of air, than with a moist atmosphere and no air. The dark season has affected no part of the Vine much, except the foliage, which is not so fully expanded as usual. The leaves are slightly contracted at the edges, and are wanting in substance and in that fine dark green gloss, which they have in clear weather; but, as to the fruit, I never saw the berries swell better, and so equally. The Black Hamburgs have that hammered appearance so much valued, and colour well, with a fine thin bloom on them. No red spider is to be seen, for the sun has never been hot enough this season to hatch them. We commenced cutting Grapes on the 25th March. We could have cut some of White Frontignan and Foster's Seedling a week earlier had I chosen. On April 6th I had almost finished cutting the first Vinery, and have cut two boxes out of the second from the hot end. The first and second Vineries are 50 feet long and 20 feet wide, and contain chiefly Black Hamburgs. The third Vinery is 56 feet long, and contains nothing but the latter variety; and in the hottest part of this house the berries are just beginning to change colour, so that they will be ready for cutting as soon as the second house is finished. The fourth Vinery is 50 feet by 20—all Muscats, which will be ready for cutting the first week in May. This is the sixth season we have forced these four Vineries thus early, and our fruit has never been superior either in quantity or quality. With respect to the best white Grape for early forcing, I find Foster's Seedling a free bearer, good setter, having large bunches, and good-sized berries. It possesses a very agreeable flavour, and is grafted on Buckland Sweetwater, which cannot be depended on as an early forcer. In black Grapes, the Black Hamburg still keeps the lead, but it is almost equalled by the Madresfield Court, which excels it in flavour. I cut the shoulder of a bunch the other day, the berries of which were as black as a Sloe, with a fine bloom. The flavour was excellent, but a few more days were required to thoroughly ripen the fruit. It is grafted on the Hamburg. As a second early and summer Grape, the Madresfield Court will become a great favourite; for a late Grape, it must be in a very dry house, for if there be any damp it is at once spoilt. JAMES SMITH.

Waterdale, St. Helens.

NOTES OF THE WEEK.

— WE desire to call attention to the note (p. 334) on the excellent samples of Seakale gathered from wild plants on the Hampshire coast, and sent us by a correspondent there. We think his suggestion that the plant should be grown everywhere by the sea-coast an admirable one. When cooked, it proved to be the most delicately-flavoured sample of Seakale we ever tasted. It is almost needless to add that the plant will grow anywhere on our sea-coasts, and that, by utilising waste ground there, large supplies of a most delicate and wholesome vegetable could be raised.

— CUT FLOWERS of the newly introduced bulbous plant, *Freesia Leichtliniana*, have just been sent to us by the Colchester Bulb Company. It has pale sulphur-coloured Auricula-scented flowers, which are borne on stout spikes 6 or 8 inches high, and in shape and substance closely resemble those of the Tuberose. Independent of its beauty, which is by no means inconsiderable, its scent alone must make it a favourite.

— THE Governor of the Bahamas reports that the cultivation of the Pine-apple is rapidly spreading through those islands. On one estate, in the eastern district of New Providence, from one spot could be seen at a glance 1,200,000 Pine-apples growing. They were well cultivated and in good order; and such a broad expanse of young fruit, set amongst sharp and distinct-looking leaves, gave a peculiar feature to the landscape. Pine-apples to the value of £55,497 were shipped from the Bahamas in 1873 to the United States and England.

— IT has been determined, by the Southampton Town Council, that all the trees and shrubs growing in the public parks there should have their botanical names attached to them. This may be an excellent intention, but its value depends greatly on the way in which the work is carried out. The labels should be something less in size than an ordinary tombstone, and of a durable material. There should be legibly printed on each the common name of the tree or shrub to which it is attached, as well as its botanical name; and if its native habitat could be added, so much the better.

— THE Acclimatisation Gardens in the Bois de Boulogne, Paris, have received a rare collection of artificially coloured plants from China. The plants are exhibited in the great glass house of the gardens, and excite universal admiration. Among the collection is a dwarf tree of half a metre in height, the trunk of which is as thick as the finger, and the root of which hardly fills the hollow of a man's hand; the specimen is about 100 years old, and is a species of Oak. This, however, is not a natural phenomenon, but the result of Chinese horticulture, which finds its highest problem in the reduction of the natural size of plants.

— IN Silesia, says "Nature," a new glass was invented a few days ago, by Herren Lubish and Reiderer, in Count Solm's glass-works, Andreashütte, at Klitschdorf, near Bunzlau. This glass, which the inventors call "metal glass," is so hard, that when a pane lies on the ground and a leaden ball of 40 grammes weight falls upon it from an elevation of 12 feet, it receives not the slightest impression; nor is it in the least affected when dipped whilst red-hot into cold water. Window panes, lamp cylinders, and other articles made from this metal glass, can therefore almost be denoted as unbreakable.

— IN Belgrave Square may now be seen a large hanging basket, simply but effectively planted with *Aucuba* and the common Ivy. The basket is a large one, fully a yard in diameter, and holds a good body of soil. A bushy *Aucuba* occupies its centre, and the Ivy forms an elegant fringe, hanging in graceful drapery fully a yard below the basket. Large baskets of this description ought to be more generally seen wherever there is room for them; and, if they are of a good size, they give but little more trouble in watering than an ordinary window box. During summer, a scarlet *Geranium* or two might be added for colour, and Crocuses, Snowdrops, Daisies, and other early-blooming plants might be employed for a similar purpose in spring.

— AFTER the long and hard winter, now, it is to be hoped, passing away, the following beautiful flowers are stated by a correspondent to be the brightest which he now has in a good collection of hardy plants, viz.:—*Saxifraga virginensis*—This little gem has pure white flowers, borne in dense clusters, and its yellow-powdered stamens give it an appearance which may not unaptly be likened to miniature Apples of gold in baskets of silver. *S. oppositifolia pallida*—This is of dwarf cushion-like habit, its soft rosy-mauve flowers being larger than in the typical species, or its white-flowered form. *S. Burseriana*—This is of upright tufted habit, its white Cardamine-like flowers being borne on rosy-carmine-tinted flower-stems, which rise about an inch above the fresh green tufts. *Soldanella montana*—This bears fresh green foliage, nearly circular in outline, or disc-shaped, and its pale purple or mauve bell-shaped elegantly-fringed flowers are borne on a nodding *Scilla*-like scape. It is a plant well worth growing.

THE INDOOR GARDEN.

ALLAMANDAS AS CONSERVATORY PLANTS.

WE find the Allamanda one of the most valuable plants that can be grown for the decoration of the conservatory in summer, there being so few flowers possessing such a bright yellow colour that can be employed for that purpose. Its long trumpet-shaped flowers, in trusses of fours and sixes, with which a few well-grown plants are studded, produce a brilliant effect where shades of red in flower and foliage are predominant; the individual flowers also last much longer in the conservatory than in the stove in summer. It is one of those robust-growing, easily-managed stove plants that do well for decoration after being grown up to the flowering point in heat. If kept out of draughts in the conservatory it will grow slowly and flower from the 1st of June to October, and the varieties best suited for this work we find to be *Hendersonii* and *nobilis*.

The former is an exceedingly free-blooming kind, showing its flowers on much shorter growth than any of the other varieties; the flowers are also larger than any excepting *nobilis*, and, being of a less scandent habit, it can be more easily grown into a shapely plant by tying it to a few sticks round the margin of the pot. *Nobilis* is a more robust grower; and, unlike the other, which is smooth in all its parts, both its wood and foliage are covered with fine hairs; the flowers are a paler yellow, but very much larger than those of *Hendersonii*. It is, in every respect, a noble flower. Cuttings of all the Allamandas are as easily struck in a propagating-pit, and on a bottom-heat of 80°, as *Fuchsias* are; in a common dung frame under bell-glasses they will root in twelve days. Cuttings should be made of short-jointed half-ripened wood, and inserted singly in thumb-pots, so that they can be safely shifted on without injuring the young roots. The points of the newly-struck cuttings should be pinched out, and, after further growth to two or three joints have been made, the points should again be pinched out and the shoots tied outwards to sticks, thus laying the foundation for a future plant of good shape; when this has been accomplished the plants may be allowed to grow on and flower. Suppose

the young plants to be grown on in heat—in a close moist pit in which the pots are plunged in leaves or tan—attention must be paid to shifting on as the pots become filled with roots. A very fibrous, yellow, sandy loam, with a mixture of rotten horse dung, suits them admirably. The Allamanda is a gross feeder and strong rooter, and, therefore, the usual mixture of peat is not necessary. It is in the second and succeeding years of the life of this plant that we find it most useful for the conservatory. If autumn or spring-struck plants have been grown on the first season they will be good specimens in 10-inch pots by October, and will begin to ripen off. We winter them in a pit, where a temperature of 50° can be maintained throughout the dull months, the pots being plunged in old tan or leaves, just deep enough to cover them, a little moisture about the roots being supplied. Under this treatment the plants gradually lose their leaves, and they require no water whatever at the roots until the time comes round for

starting them again, for which the middle of March, or even later, will be sufficiently early. They should then be pruned back like Vines, cleaned, if necessary; then subjected to an increase of temperature, and syringed. When it is seen that the plants are just moving into growth, they should be re-potted, as much of the old soil as can be removed, without destroying the roots, being picked away; they should then be returned to the same pots, and be grown on in a light house or pit. By the end of April they may require a shift into pots a size larger. Most of our plants have been grown in the same pots for three years in succession, and flower very satisfactorily; they are, however, indulged with a regular supply of weak liquid manure. About the second week of June they are sent to the conservatory, where they occupy elevated positions, that is, they stand up in the warm atmosphere of the house, away from cold draughts, and here they flower up to the second week of October. Both species mentioned receive the same treatment; the others, such as *cathartica*, *grandiflora*, or *Schottii*, are not so well

adapted for conservatory work. For stove rafters the Allamanda is a grand plant, not only on account of its growing and flowering habit, but also because it remains unmolested by insects, and, therefore, the plants grown underneath are not disturbed or injured during any cleansing process, as sometimes happens in the case of kinds more liable to be infested by these pests. W. D. C.

Large-spathed Flamingo Plant (*Anthurium Scherzerianum*).

THE FLAMINGO PLANT.

(*ANTHURIUM SCHERZERIANUM*.)

AT the spring exhibition of the Royal Botanic Society, held on March 31st, Mr. Ward, gardener to F. J. Wilkins, Esq., of Leyton, exhibited a vigorous specimen of this species, bearing four remarkably large spathes. Our illustration, sketched at the time when it was exhibited, will give our readers some idea of the appearance of this large-spathed variety, which, for healthy luxuriance, we have never seen excelled. The broad flat spathes were fully 5 inches in length and 4½ inches in breadth, and attracted much attention. In colour these spathes were not so brilliant as those of some of the other varieties exhibited on that occasion; but perhaps spathes produced under more favourable circumstances, as regards weather, may be brighter. Like all other cultivated plants raised

from seed, this *Anthurium* is very variable in habit, size of spathe, and brilliancy of colouring; and this variety is now further augmented by the introduction of a whitish-spathed kind, which we hope will prove a charming companion to the crimson or orange-scarlet-spathed varieties. B.

GOLD-LACED AND OTHER POLYANTHUSES.

I SHOULD infer, from the many enquiries I am constantly receiving, that the old Gold-laced Polyanthus is again likely to become popular with many lovers of flowers. Scarcely a week passes during the winter, but some one is found asking where such fine old sorts as Sanders' Cheshire Favourite, Hufton's Earl of Lincoln, Cronshaw's Exile, and Buck's George the Fourth can be obtained. These and eight or nine others were much grown from twenty-five to thirty years ago, and I had feared some of them had entirely gone out of cultivation; indeed a few of them may have quite died out. Of our

best known present Polyanthus cultivators, I can instance the veteran John Read, of Market Rasen; William Alsebrook, Sheffield; and the Rev. F. D. Horner, Kirkby Malzeard—who is, floriculturally speaking, “the worthy son of a worthy sire.” A visit to either of these gentlemen at this season of the year, would prove a treat to any lover of this fine old florists’ flower. To do full justice to the exquisite beauty of the Gold-laced Polyanthus, the plant must be grown in pots. Polyanthuses in the open air thrive but poorly when the cold winds of March sweep across our gardens, and shrivel up the delicate blossoms of our early spring flowers. The Polyanthus should be in a cold frame, near the glass, where the plants can have plenty of light and air, to keep them from becoming drawn. Top-dressing is done now. The reason for this is at once seen by anyone conversant with the habit or growth of the Polyanthus. At this time of the year, the spring growths are being matured, and these growths spring from near the collar of the plant, and they throw out rootlets near the surface. These rootlets should have something good to root into, for the plants derive a great deal of sustenance through them; hence the practice of top-dressing. The florists who grow this flower for show, use thoroughly rotten horse and cow-dung, and maiden loam, in about equal proportions. No cold winds or frost are allowed to come near the flowers, as they are likely to do injury to them. The direct influence of the sun must also be guarded against, as hot sunshine will mar the beauty of the blossoms. There are yet many who, for want of accommodation, grow the Polyanthus in the open ground, and that most successfully. The bed is carefully prepared in the autumn, by digging it deeply, and manuring well with thoroughly rotten cow or horse-dung and plenty of leaf-soil, and by the beginning of November, the plants are planted out. The Polyanthus will stand a great deal of moisture at the root during winter, provided there be a free circulation of air; and it is always well, when severe wintry weather threatens, to shake some Fern or other loose litter over the plants, to screen them from injury. By the middle of March a movement of growth will take place, and the flower-spikes will begin to show themselves. The soil should be stirred about the plants to the depth of 1 inch, taking care to avoid doing injury to the roots by disturbing them, and the bed should be top-dressed with a compost like that recommended for plants in pots. When this is done, some shelter should be extemporised from cutting winds. One of the best means of obtaining this shelter is to cut some branches of the Spruce Fir into small pieces, and stick them about the beds to windward of the plants, and in this way an excellent screen is obtained. During the last two or three years a fine strain of decorative Polyanthuses has been obtained, and designated as a fancy or mottled section. The plants are all of vigorous growth, and they throw up bold trusses of flowers on strong foot-stalks, the blossoms being of great size and beautifully marked. From pure white, through yellow, pale lilac, rose, bright purple, magenta, and crimson, these Fancy Polyanthuses vary in colour, and having plenty of robustness of constitution, they are invaluable for beds in early spring, for mixed borders, and for cultivation in pots. A good soil is required, and the more attention they receive the more beautiful are their flowers. Last year, the Royal Horticultural Society certificated two or three types, so finely were they shown at some of their meetings—a measure of encouragement they well deserve. These few seasonable notes would be incomplete without mention of the new single Primroses that have been raised and exhibited of late. The yellow Primrose of our hedges and woods has developed into a flower of great perfection and beauty by means of careful fertilisation. White and yellow, lilac and purple, rose and red, magenta, scarlet and crimson, and even blue shades, have been obtained. Such varieties as Violet Gem, Auriculæflora, Rosy Morn, Sunrise, Violacea, Lilacina, Splendour, Fairy Queen, and Sulphurata, may be mentioned as worthy representatives. All the qualities most dearly prized by the florist—form, outline, substance, brilliancy of hue, &c.—are here present, and, in addition, they flower early, profusely, and continuously. They are remarkably fine when cultivated in pots, after the fashion of the Polyanthus; but they do not require any nursing, for they are as hardy and robust in character as the common Primrose of the roadside.—R. DEAN, *Ealing*, in “Florist.”

NOTES ON CAMELLIAS.

FIMBRIATA Improved is a very beautiful Camellia, compared with which the ordinary fimbriata is smaller in the foliage, but larger and fuller in the flower. There is also an Oak-leaved variety of fimbriata which does not appear to be of any great value. Jenny Lind is a fine variety in colour—white spotted with pink; it is neat in shape, but is rather a shy flowerer. In the same class as the latter is Countess of Orkney, a beautiful creamy-white with some delicately marked red petals in the flower. This plant has rather a straggling habit of

growth. Cup of Beauty, a kind similar to the last-named, is a fine sort, though the plant when in fair health sometimes has a sickly appearance. La Reine is one of the most beautiful, and it would be difficult to adequately describe the fine marking of some of the flowers. Comte de Paris is also very pretty for variety, being white, tinged and striped with pink. Amongst reds, imbricata, like the old alba plena amongst whites, is almost too well known to need mentioning; yet it is still among the best for the conservatory. Reine des Fleurs is a most beautifully-arranged red flower, having a semi-drooping habit. Monarch is a very good sort—a strong grower and profuse bloomer, of a lively red colour, showing some stamens in the flowers. Amongst small reds is miniata, which is of very neat shape, and a very useful variety for cut flowers. Henri Favre is not unlike miniata, and is also of a valuable kind, of a somewhat larger size, with a shade of pink in its centre. Amongst large reds, Mathotiana is a noble-looking flower, measuring fully 4 inches across. Augustine superba is a delicate pink and handsome flower, but it is not a vigorous grower. Hendersoni is also a very good and neat pink. Princess Marie, a very ornamental pink, grows and blooms freely. These observations are based upon an examination of a well-established collection of plants of a fair size, which have been making a brilliant display in a large conservatory since October last.

Abney Hall, Cheadle.

ROBERT MACKELLER.

Azaleas and Camellias on bottom-heat.—Would Azaleas and Camellias be benefited by putting them in a cold brick pit with 2 feet of horse-dung and leaves under them, the plants being set on bricks above the heating material to make their growth; would the rank steam out of the dung injure the foliage; or would the plants be best put in the pit without the fermenting material?—W. T. C. J. [I should not advise the use of fermenting materials in a pit in which Azaleas and Camellias are placed to make their growth, as the vapour rising from them in the night, when the pit would require to be closed, would make the young leaves (especially in the case of the Azaleas) too soft and not able to bear the amount of sun necessary to solidify and give them, as they grow, their wonted substance. In the southern portion of the kingdom Azaleas and Camellias, except where required to flower early, will, under good management, make their growth and set their flowers without the assistance of artificial heat. The principal thing to observe is to close the house or pit, in which they are placed early in the afternoon, whilst there is yet some hours’ sun upon the glass, and not to give more air during the day than is necessary for the health of the plants and to prevent scorching. Camellias will succeed further from the glass than Azaleas, but will, of course, require more shade. Azaleas, especially whilst making their growth, cannot be placed too near the glass, and (except the small-leaved varieties, that is, those of the *Gledstanesii* and *variegata* type) are better shaded but slightly, and this only in the hottest part of the day in bright weather. Whilst the plants are growing, use plenty of moisture in the atmosphere, and syringe freely overhead when the house is closed. Azaleas, at all times, require more water at the root than the generality of hard-wooded greenhouse plants. Camellias, especially whilst growing, should have it in abundance. Keep the Azaleas free from their great enemy—thrips—otherwise it is impossible to grow them well. On the appearance of this pest, syringe them thoroughly with tobacco-water, laying them down on their sides to prevent its getting to their roots.—T. BAINES.]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Large Spathes of Anthurium Scherzerianum.—The spathes of Mr. Ward’s plant of this (see p. 274) being considered very large, I may mention that at Sedgwick House, near Kendal, I saw the other day six spathes, the largest of which measured 6½ inches in length, and 4 inches in breadth. Mr. Bethell, the gardener, informed me that last year some of the spathes measured 7 inches in length, and nearly 5 inches in breadth.—G. S. FRIEND, *Portwilliam*.

Phajus grandifolius a Cool Conservatory Plant.—Conspicuous amongst plants that are now in bloom is the *Phajus grandifolius*. When well grown its handsome shape and stately appearance render it worthy of general cultivation for decorative purposes. It is easily cultivated, and stands well and long in the cool temperature of the conservatory, where it contrasts admirably with the varied types of vegetation.—G. WESTLAND, *Witley Court*.

Falconer’s Sikkim Rhododendron (R. Falconeri).—This is now in flower here; the plant itself, with its large dark leaves clothed on the undersides with a brown woolly substance, has a fine appearance; but when in flower it is exceedingly chaste and beautiful. The specimen of it here has produced a truss consisting of thirty creamy-white flowers, each of which measures from 2 to 3 inches across, and the whole truss about 2 feet 5 inches in circumference, forming a complete ball, which, being well up above the foliage, is shown off to advantage. This Rhododendron is seldom met with in general collections of greenhouse plants, a circumstance perhaps attributable to its being a shy bloomer; be that as it may, however, it is one of the finest of all greenhouse Rhododendrons.—CHAS. J. WHITE, *The Knoll, Baildon, Leeds*.

THE FLOWER GARDEN.

THE DOG'S-TOOTH VIOLET.

(*ERYTHRONIUM DENS CANIS*.)

WHEN, in early spring, the Orchids begin to blossom on the mountain fields of southern Europe, and the Hepatica sprinkles its stars under the Brambles, and in nooks everywhere, a beautiful and strange-looking flower is seen here and there on the mountain sides, among the stones and Grass. The flowers of this droop somewhat like the Cyclamen; and, though a very small plant, it has a flower of a lovely rosy-lilac, so large as to remind one of those tropical climbers more than of a true Alpine flower, which it is. The foliage, also, is singularly unlike any other Alpine flower, being deeply spotted with brown, so as to resemble some of the fine-foliaged plants popular in our stoves. This flower is the Dog's-tooth Violet, long known as an inhabitant of our gardens, but which, with many other flowers, has been for some years so neglected, that it was only in a botanic garden, or curious collection here and there, that one ever caught a glimpse of it. There is no flower known more worthy of a place in our gardens. It has several beautiful relations, mostly natives of America, but as yet scarce in our gardens. They will probably not be long so, as the fine *E. grandiflora* is abundant in the Rocky Mountain and Utah region; while the yellow Dog's-tooth Violet is common among the wild herbage in many parts of the Eastern States, as the Daisy is in our lawns. In our gardens the Dog's-tooth Violets thrive best in warm sandy soils; indeed, the beautiful European kind, the finest of all, is only seen in perfection in warm soils. It will grow in any kind of soil, but on cold clays one must frequently be content with the beauty of the leaf only, as the blossoms are not formed. Where clay soil occurs naturally, it is best to grow the plant in prepared soil, in a raised position, in the lower parts of the rock-garden or hardy Fernery. Where sandy peat or free loam admits of its thriving perfectly, the Dog's-tooth Violet should be abundantly grown, among the bulbous flowers that bloom in early spring, and it will look well either in clumps or small beds, or as a carpet beneath choice American shrubs in peat soil. The leaves die down more rapidly than those of most bulbs, and care should be taken that it is not injured by accidental disturbance. As a carpeting plant to small beds of choice growing shrubs, it would probably be as little liable to accidental destruction as in any other position. The roots of this plant suffer from being kept dry; and, therefore, they should, when taken up for any purpose, and not replanted soon, be stored in Cocoa-fibre or wet sand. We have never seen this plant in such good condition as in Messrs. Barr & Sugden's trial ground at Tooting, where large beds of it are studded over with its showy blooms. Mr. Barr cultivates the following varieties:—*E. dens canis album*, *majus* (red-purple), *majus roseum* (rose-purple), *majus album* (white, bottom of flower brown), and *Passiflora* (light purple, shading to blue).

A RIVAL ROSE TO COUPE D'HEBE.

I HAVE read, with pleasure and profit, "H. G.'s" useful remarks on Roses (see p. 270), and I quite agree with all he has said with the exception of his statement that we have in Auguste Mié a hybrid perpetual Rose nearly equal in shape and colour to the hybrid Bourbon Coupe d'Hébé. Of course the expression "nearly equal" is somewhat vague; but, assuredly, although Auguste Mié is a most valuable late autumn Rose, it is a long way from being like Coupe d'Hébé in colour or even in shape. It is always a great many shades lighter than Coupe d'Hébé, which is in fact the most perfect Rose in form and colour that we have, and a Hybrid Perpetual possessing the same qualities would be, indeed, a prize. At the risk of being criticised by "H. G." and others, I venture to name a Rose that much more closely resembles Coupe d'Hébé than Auguste Mié, and that is Charles Lawson. I have cut half-open buds of both so much alike in form and colour, that good judges have been puzzled to distinguish them in Rose vases. And yet, in general, Charles Lawson Roses are widely different from the matchless beauty of form and colour possessed by Coupe d'Hébé. I am surprised that the latter is not more grown as a standard than it is. It forms splendid heads, and, although it is not in any sense a perpetual Rose, yet it yields a long succession of flowers, for the branches

often show, at different times, fine clusters of threes and fives, which take much longer to come out than a single flower. Besides, a dozen or so of standards of Coupe d'Hébé, should be grown for its leaves alone, which prove invaluable for the autumnal dressing of vases and baskets of Roses. Indeed the foliage of this variety is the best of all for fringing bouquets of Roses. Charles Lawson, perhaps, also comes nearest to it in the usefulness of its foliage, a point rather too much lost sight of in the case of some of our Roses; for, in furnishing with Roses, it is often much easier to find fine flowers than the requisite quantity of fresh leaves and branches. One of the prettiest Rose bouquets may be made of the two varieties, Coupe d'Hébé and Boule de Neige. Buds and flowers, of different sizes, of these two, with the finest foliage of the former, form a charming combination. Coupe d'Hébé was the favourite Rose of my late employer, Lady Cullum, who, amid all the novelties and excellencies of the newer Roses, never gave up her ardent appreciation of Coupe d'Hébé.

D. T. FISH.

A VARIEGATED PRIMROSE.

(*PRIMULA VULGARIS* VAR. *VESUVIUS*.)

OF this, which is one of the prettiest of the variegated or fancy-flowered hardy Primroses, blooms were sent to us the other day, in beautiful condition, by Mr. Clapham, of Scarborough. It is very nearly related to the Polyanthus section, and not unfrequently produces its

A Variegated Primrose (*Primula vulgaris* var. *Vesuvius*).

rich violet-purple white-margined flowers several together on a scape. Mr. Clapham, indeed, remarks that he bought it in the Polyanthus state—that is, having many flowers on a stalk; and that, after a time, he was surprised to see it produce single flowers, as in the case of the common Primrose. Primroses, in short, have been crossed so frequently by florists, that their varieties are innumerable, and their characteristic peculiarities are in many cases confused or combined in the most perplexing manner—a fact well known to old cultivators of such flowers about the beginning of the last century. B.

PROPAGATION OF ALTERNANTHERAS.

ALTERNANTHERAS are much used in pattern and ornamental bedding, and as, in some places, it is hard to get a good stock, the following description of the method of propagation that we adopt may be found useful. In the autumn I take up a sufficient number of old plants, put them into 48-sized pots, and place them in a hotbed till they have rooted afresh. They are then placed on a warm pit or stove shelf through the winter till the present month. I make up a hotbed this month for them, and remove them into it, placing some cocoa-nut fibre between the stems of the plants. In about three weeks the plants are covered with young shoots, and all are well-rooted from the joints. So soon as they are grown sufficiently, the old plants are cut up into small pieces, some plants thus supplying fifty rooted cuttings. These cuttings are all potted off into small 60-sized pots, and plunged in the hotbed as thickly as they can be stowed away. The compost used is equal parts of loam, leaf soil,

peat, and plenty of sand. The glass requires to be whitewashed over with lime or whiting, so as to give the plants about the same amount of shade as is given by the use of canvas; they require to be kept very close while growing, and the shading must not be removed till the plants are large enough for bedding; keep up a moist heat by syringing night and morning, so as to encourage the growth. As soon as the plants are grown to the size required with occasional picking over to make them bushy and equal in size, the shading may be partially washed off, and more air given so as to colour them, as they will be found to have little or no colour while growing. As soon as the colour begins to show itself, and the plants are more hardened to the sun's rays, the whole of the shading must be cleaned off, and the plants get the full rays of the sun with sufficient air to keep them from burning or scalding; syringe every evening when the pit is closed. Soon after the full power of the sun is thrown on them, the plants get the required colour. After the colouring process is over, the lights may at first be taken off by day till they get sufficiently hardened to take off altogether. The above is a simple plan, but it saves time and the trouble of getting cuttings, and is a sure plan of getting good plants for bedding. The *Alternanthera* does not make growth in a stove or pit exposed to the full rays of the sun, but always requires shading under these circumstances. H. G.

NEW KINDS OF NEW ZEALAND FLAX.

AMONGST foliage-plants, the different varieties of New Zealand Flax deserve a leading position. To the original type (*Phormium tenax*) have been added six varieties, of which five are very ornamental. *P. tenax variegatum* is not only remarkable for its size, but also for its beauty. Its leaves grow obliquely to a height of 10 feet, and without becoming actually pendent are curved down gracefully at the points. The edges are green, and the centre a very beautiful yellow. The only drawback to this variety is that it too seldom produces off-sets by which it may be multiplied. *P. tenax Veitchii* is a magnificent and very vigorous variety, the leaves of which are straighter than those of the preceding kind, and are of a striated yellow. *P. tenax Colensoi*—The appearance of this plant is very handsome; the leaves are long, slightly curved, and striated yellow in colour. The plant is a very vigorous one. *P. tenax Cookii* is a compact plant, the leaves of which are comparatively short, stiff, straight, and of a variegated yellow colour. This variety, from which numerous suckers may be obtained, has the fault of being inconstant; it almost always produces suckers that are completely green, and others from which the slight variegation rapidly disappears. *P. tenax Saundersi* is a dwarf and stiff plant, the leaves of which are short, straight, and upright. The small dimensions of this variety fit it for introduction into small beds. *P. tenax atro-purpureum* is a very robust and vigorous variety, of a fine appearance, which reminds one of its type. Its leaves are very large; not variegated, but having a beautiful glaucous violet tint, which varies according to the growth of the plant, but never disappears. This is a highly ornamental and very remarkable plant, which unfortunately is still uncommon. The New Zealand Flaxes require a consistent and rich soil; a mixture of friable and leaf mould is adapted to strong plants; the off-sets should be planted in dry soil, coarsely broken up, that is to say, not pulverised. Waterings, which must never be neglected, should be frequent and copious when the plants are rapidly growing. The *Phormiums* are propagated from off-sets, which produce the strongest plants. To hasten the growth of the parent plants a bed should, about the first fortnight in May, be made in the open air or under a frame; this is then covered with sand and peat, in which the plants are placed; the soil is covered with a good mulching, and it is kept damp with frequent waterings. In the autumn the plants are lifted, and the off-sets detached. They are then potted, and placed in a close house, in which there is a brisk temperature. When the appearance of the parent plant is not a matter of consideration, off-sets may be more rapidly obtained by piercing here and there with the blade of a grafting knife the leaves which form the heart of the plants.—“*Revue Horticole*.”

Pansies for Spring Bedding.—When is the best time to plant seedling Pansies for spring decoration, and is manure beneficial to them?—*ENQUIRER*. [If not already done, these should be planted at once, as, in order to make a good display of bloom during April and May, they should be now good strong plants and full of buds. As a rule, the best way to get a good display of Pansy bloom in spring from seedling plants is to sow the seed in pans or boxes about the second week in July, and, when the seedlings are large enough, they should be pricked out into some shady place and kept watered until well rooted. These should make strong plants ready for bedding out directly the tender summer plants are removed; and, if the

soil about them is carefully stirred in the spring, they will soon make a brilliant display. Should the soil be very stiff and disposed to become hard during the winter, it is well to allow the planting out to stand over until March, by which time it should be well pulverised. Strong fresh manure is not good for Pansies, but they will thrive all the better for a good dressing either of old frame manure or rotten leaf soil.—A. D.]

Humea elegans as a Fine-foliaged Plant.—This has long been highly prized for the graceful pyramid of rosy-tinted flowers which it produces; but, it may not be generally known that its foliage alone renders it a valuable plant in the sub-tropical garden. It is superior in appearance to the various kinds of Tobacco plants, and its leaves have a distinct and powerful perfume. In order to have its foliage in perfection it must not be sown earlier than the end of September; it should then be grown on gently through the winter, in an intermediate house, and gradually hardened off by bedding-out time. Plants of it thus raised will show no disposition to flower; on the contrary, all their energies will be concentrated on the formation of foliage. As single plants for the centre of beds, or in groups, with the ground carpeted, they are very effective, and form immense specimens by the autumn, when it takes a considerable amount of frost to injure them. They will be found to be valuable for lifting, where large plants for conservatory or room decoration are in demand in winter.—*JAMES GROOM, Henham Hall*.

Sedum amplexicaule.—I think it must be conceded that Mr. Ellacombe's remarks respecting the suitability of this *Sedum* for carpet-bedding, would apply with equal force to *S. Lydium*, *glaucum*, and others, now so commonly used for that purpose. These, if scorched by the sun, and deprived of moisture, have a very withered appearance; but where grown on rich and deeply stirred flower beds, and well-watered during drought, are amongst the most useful and effective of carpet plants. My plant of *amplexicaule* is spreading over the soil with great rapidity, rooting in all directions, and, ere the close of the summer, I anticipate that it will have reached a diameter of 12 inches. As it has a close, compact, creeping habit, it entirely covers the soil as it proceeds. *Sedums* are usually commended as excellent rock plants, and during the winter months they will thrive fairly in such situations; but they suffer greatly during the summer. Now my experience of these creeping *Sedums* is that the better the soil, and, within limits, the moister they are kept, the better they thrive. Just a year ago, when planting out a narrow north border with Double Primroses, I pricked out along its margin a line of *Sedum Lydium*. This grew so rapidly that, ere the close of the summer, it formed a perfect evergreen edging about 6 inches in width. Of course it received a portion of the water supplied to the Primroses twice a week, and the treatment agreed with it. This same row has remained vigorous all the winter, and it would seem that cold and wet are less likely to damage it than heat and drought, for a similar edging in a hot dry border was nearly withered up.—D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dog's-tooth Violet not Flowering.—I have some purple Dog's-tooth Violets in a border of rather sandy soil; they have been there two years, and produce leaves in abundance but no flowers. Can any reader of THE GARDEN kindly tell me why they do not flower?—*H. A., Guildford*.

Spring-flowering Shrubs for Terrace Walls.—Two very ornamental spring-flowering shrubs for planting together on terrace garden walls are—*Cydonia japonica*, with its large scarlet blooms, and the beautiful *Forsythia suspensa*, which is a bright yellow. When well grown, they have a splendid effect in combination.—*A. H., Thoresby*.

Hardiness of *Aralia japonica*.—It is not sufficiently known that this strikingly handsome foliage plant is perfectly hardy. In the spring of 1872, I planted out several specimens of it, thinking they might answer as “sub-tropical plants,” and they have more than fulfilled my expectation; and though they have not had the slightest protection, they are at this moment unscathed, and in full vigour of growth. All lovers of beautiful-leaved plants should use this *Aralia* largely, either for growing in the centre of beds, or as isolated specimens on the lawn.—*W. WILDSMITH, Heckfield, Hants*.

***Linaria alpina*.**—Has this pretty continuous-blooming border plant ever been used for grouping in beds, or for rows in the flower garden? I imagine it might be worth trying. How much more interesting it would be if possessors of villa gardens, who persist in having masses of colour in their flower-beds, would use some of our hardy plants instead of such as are comparatively tender. Numbers, of all shades of colour, may be had, which, by simply keeping the flower vases well supplied with cut flowers from them, will flower till late in the autumn. Pentstemons, *Antirrhinums*, *Delphiniums*, &c., bloom thus if constantly cut from.—*R. P. B.*

Spring Gardening (Golden Feverfew and Forget-me-nots).—The past winter has proved, I think, that it is not safe to trust entirely to the plants of Golden Feather *Pyrethrum*, which were used in the summer bedding, for effect in the spring. Usually, for a few winters, I have arranged the Golden Feather in the May planting, so that it would do for the October planting, but I find that will not do. Lines and blocks of it all over the place have most irritating gaps in them. It must be sown in the summer, say with the Cabbages, and transplanted in autumn. Plants of *Myosotis dissitiflora* raised by division of old roots are not as hardy and frost-resisting as are seedling plants. This spring my old plants of *Myosotis dissitiflora* are nearly all gone, whilst the seedling plants are all safe. *Sylvatica* is here much hardier than *dissitiflora*, but not so easy to bloom.—*N. H. P.*

TREES AND SHRUBS.

THE OLIVE TREE.

(OLEA EUROPÆA.)

THE OLIVE is one of the most celebrated and valuable trees of the Old World, in many parts of which its culture forms the chief occupation of a large portion of the inhabitants. It cannot endure excessive heat or cold; therefore it thrives best in a mild equable climate. Its northern limit may be fixed at 42°, beyond which it is stunted and unproductive, although it frequently produces flowers in abundance. There are two varieties of the tree cultivated in Europe and Africa, viz., the long and broad-leaved Olives. The first is cultivated in France, Italy, and Greece, and yields the Olive-oil of commerce. The fruits of the broad-leaved Olive, which is cultivated in Spain, Portugal, and Morocco, is almost twice as large as that of the long-leaved kind, and has a strong and somewhat rancid taste. Without being strikingly handsome or imposing, the Olive is a picturesque tree. Its rough, gnarled trunk is erect, and often of considerable thickness, but seldom more than 10 or 20 feet in height. The bark is a dull grey, and, upon young trees, very smooth. The branches are numerous, regular, and massive, and clothe the trunk almost from its base to its apex. The leaves, which are not unlike those of the Willow, are small, lance-shaped, and ever-green. The flowers are small and white, and grow in clusters in the angles formed by the leaf-stalks with the twigs. The fruits, which consist of oval, unilocular drupes, are soft and pulpy, and contain a hard oblong kernel. During their various stages of development, they repeatedly change colour, being at first green, then pale, afterwards purple, and finally quite black when ripe. Both varieties of the European Olive have been transplanted to Mexico, Peru, California, and various other parts of America. It thrives well upon the western coasts of that Continent, especially in Peru and California. In 1870, there were 29,303 Olive trees in the latter country, where a large share of attention is now given to their culture.

Propagation.

In Italy and France the most common method of propagating the Olive is by means of layers. The branches selected for this purpose are pegged down and carefully covered with earth in winter, and are ready to plant out in the succeeding spring. Another method is to select strong roots, which are cut into lengths and planted with the lopped end slightly above the surface; in a few weeks each root sends forth a young shoot. Propagation is also effected by means of cuttings selected from strong healthy branches and planted in spring. In some parts of Italy it is a common practice to cut an Olive trunk into pieces, each about the size of an average Mushroom, to steep them for some hours in liquid manure, and then to plant them out in beds like Potatoes, covering them with a layer of earth from 3 to 4 inches deep; in a short time young shoots make their appearance, and in about sixteen months they are ready to be transplanted. Trees raised from seed are invariably of an inferior description, and produce only small bitter fruits containing little oil. Olive trees are generally two years old

when they begin to bear; they thrive best upon a calcareous or argillaceous soil, in sheltered situations and in valleys. The sea air seems to have a beneficial influence upon them, for trees planted near the coast are much more productive than those which are at a distance from it. Olive plantations are laid out in regular lines, the trees standing 30 or 40 feet apart, and various vegetables are planted in the intervening spaces.

Distribution.

The native country of the Olive appears to be in the regions around Aleppo and along the coast of Palestine, whence it was transferred to Greece. It was introduced into Italy B.C. 562, and was first planted in England in 1648. In the south of France and in the north of Spain it is a comparatively stunted tree, seldom exceeding 9 or 10 feet in height. The finest and most productive trees grow in Crete, where the best fruits are produced. The Olive possesses great vitality, and in its culture requires comparatively little care. Upon the Mount of Olives, at Jerusalem, there are Olive trees more than 2,000 years old, and in Crete there are also very old plantations still in full vigour. The age of a remarkable Olive tree at Villefranche, near Nice, is supposed to be 800 years. Its trunk, which is only 19 feet high, is 40 feet in circumference at the base. The fruit, however, begins to degenerate when the trees are about 100 years old. The wood of the Olive tree is of considerable

value, and is much employed by cabinet makers. It is close-grained, heavy, and fragrant, and capable of receiving a beautiful polish. Of other species, besides the European, the most important is the American Olive (*Olea americana*) and the Asiatic Olive (*Olea fragrans*), the leaves and blossoms of which are used by the Chinese for flavouring tea. The ripe fruits are gathered in September, October, and November, and after being thoroughly fermented, are crushed in mills,

in order to extract their oil. The best oil comes from Nice, Genoa, and Florence. The Greek and Cretan sorts are not so good, owing to the inferior method of preparing them. Olives for dessert are gathered when unripe, and are preserved in salt and water. The preserved Olives of Genoa and Marseilles are said to be the best.

JOHN HUTCHINSON, M.A.

Large Yellow-fruited Hawthorn (*Crataegus lobata serotina*).

A LATE-FRUITING HAWTHORN.

(CRATÆGUS LOBATA SEROTINA.)

THIS is the latest of all the *Crataeguses*, and therefore has not inaptly received the name of "serotina." It is a vigorous kind that attains somewhat large dimensions, being about 25 feet in height and most ornamental in appearance. Its leaves are large and handsome in shape; the fruit, when ripe, is of a very beautiful yellow colour, marked with brown specks, and ripens after most other trees have shed their foliage, a circumstance which gives additional value to this Hawthorn for ornamental purposes. Although in general appearance it bears a close resemblance to *G. lobata*, to which it is related, it is nevertheless very different as regards the period of ripening its fruit, and the persistency of its foliage. Thus, whilst *G. lobata* has spotless fruit, of a beautiful golden-yellow, which are larger than those of *G. lobata serotina*, and ripen in September and October, the fruit of the latter is regularly speckled with brown, and does not ripen till much later. Again, the leaves of *G. lobata* disappear in October,

whilst those of *G. lobata serotina* remain upon the tree throughout the entire season.

IVY ON EVERGREEN TREES.

Just 20 yards from where I am writing stands a fine, healthy *Pinus excelsa*, about 40 feet high, and 20 feet in diameter through the branches. I planted it 20 years ago, and not far from an old wall covered with Ivy; the voracious climber soon formed a dense carpet under the tree, and then ascended to its very top, and about three parts up the tree it forms a fine evergreen canopy, producing an abundance of berries for the starlings, the only birds I have ever seen eat them, and then only at breeding time. I made a tour to-day to view the trees that surround Lord Poulett's park, as I knew that the Ivy there had taken possession, and held its own against everything else, proving how the strong destroys the weak in the progress of development. As to its dislike to the Pine tribe, that opinion may here be quickly disposed of, for the Ivy has taken possession of thousands of trees, to which the Pine forms no exception; great numbers of Scotch Fir, and hundreds of towering Silver Fir, are clothed to their topmost branches with Ivy; and, although I carefully inspected the woods, I could find but few exceptions to its likings. Even the Beech, upon which "*Salmoniceps*" says (see p. 311) it grows sparingly, is, in many instances, pretty well covered. I must, however, say that the Ivy has an evident dislike to it, as it is the only tree, amongst the many other kinds in these woods, on which it makes but partial progress; the cause of this is doubtless owing to the bark of the tree being so hard and smooth that very little moisture is retained upon it, hence the rootlets of the Ivy cannot get moisture enough to sustain the plant. I now come to evergreen shrubs generally. On these I find but little Ivy; on most that I have examined none. Growing in front of my window is a large bank of luxuriant Ivy, and amongst it are the following:—*Cupressus Lawsoniana*, *Cryptomeria elegans*, *Euonymus japonicus*, *Thuja Lobbii*, *Thuja orientalis*, and some large bushes of *Aucuba*; on none of these has a twig of Ivy taken hold; nor has it laid hold of the smooth bark of the Mountain Ash, or of the Lime, and upon these I never have seen it grow. The Holly, too, does not seem to be one of its favourites. I have, however, recently found that my large *Wellingtonia* has got into its toils; a strong plant near it has run up its trunk 5 or 6 feet, and seems to embrace it with a firmness that augurs a determination not to relax its hold.

J. SCOTT.

Merriott.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Red-rot of Pines.—This is said to be caused by the penetration and diffusion of the mycelium of a fungus (*Trametes Pini*) in the heart-wood, whose reproductive parts appear on the outer surface of the branches, especially in branch holes. The spores produced fall on the exposed surface of newly broken off branches, and thus red-rot may soon become widely spread.

Oak Galls.—According to Dr. Hollis these are divisible into two classes: one-celled, to which belong the woody Oak galls and the Currant galls; and many-celled, such as the spongy Oak-apple and the Oak-root gall. He believes that most, if not all, are formed during the growth of the leaf, the egg being laid in the bud; and that the different layers of the leaf can be made out in those of the gall.

Moving Evergreens.—Evergreen Oaks are the most difficult of all evergreens to transplant successfully. Before attempting to do so, they should be prepared by digging round them a year previously, and filling the trench with light, rich vegetable mould, in order to induce fibrous roots. As the plants which your correspondent wishes to operate on are large, I should advise him to thin out and lighten their heads, and to bind up the stems with Moss or hay-bands to keep the bark plump. The best time to transplant *Wellingtonias*, *Deodars*, and, indeed, all evergreens, is just as the buds are beginning to burst. There is no difficulty in transplanting *Hemlock Spruce* if done in the spring at this stage.—J. SHEPPARD.

Dead Clippings of Yew more Poisonous than Green.—During one winter here, when the old gardens and shrubberies were about to be done away with, the deer from the park frequently got in and cropped the Yews more than any of the other Evergreens. A few of the old bucks could not be kept out, for they jumped the fences nearly every night; but I never could find out that any of them were poisoned by eating parts of the trees when green, although the park-keeper thought they got thinner by doing so. Eating the Yew, however, is certain death to horses and cattle when the dead clippings or branches are left in their way; and I have known serious losses that have thus occurred. Many use sprigs of Yew for sheltering Peas and other tender vegetables in early spring; they should, therefore, be careful to burn them when no longer required.—WILLIAM TILLERY, *Welbeck*.

***Garrya elliptica* for Vase Decoration.**—I find cut spikes of this useful at this time of year, when flowers are scarce, for vase decoration. I have been cutting them for about six weeks, and they will last good another fortnight. A vase, the centre of which is filled with flowers, draped with them has a pleasing appearance. So fine a plant as we have here of this *Garrya* is seldom met with; it measures 12 feet in height and 10 feet in diameter, and it is covered with bloom from bottom to top. This shrub is perfectly hardy, but if it is not in a sheltered position frost sometimes injures the catkins. Give it, however, a dry soil, a south aspect, and shelter, and it will well repay any little trouble that may be bestowed on it. On walls and fences in cold situations, it does fairly well; but it succeeds best in the form of a bush, and it should never be pruned, as by cutting off the points of the young wood the bloom is destroyed.—W. DYERS, *Wierton House, near Maidstone*.

THE FRUIT GARDEN.

THE GOOSEBERRY.

(*RIBES GROSSULARIA*.)

THIS well-known and most useful fruit is a native of the north of Europe. In its wild state it bears small round or oval berries, which weigh one-fourth of an ounce; but it has been so greatly improved by cultivation as to produce fruit 2 inches in diameter, and weighing nearly 2 ounces. The plant is hardy, although the blossoms and young fruit are very liable to suffer from late spring frosts. It succeeds well, near the level of the sea, in the most northern parts of our island, and in Lancashire, Cheshire, and Yorkshire, it has been most carefully cultivated. Numerous Gooseberry shows are held in these counties; the Lancashire weavers especially devote much time and skill in bringing the berries to perfection. In the south of England the Gooseberry is frequently over-heated in ripening, unless care is taken to plant the trees in a rich and well-manured soil, and to prune them in such a manner as to afford sufficient shade. In America, a few varieties of the English sorts, and some of American origin, succeed tolerably well, and their growth near large cities is a source of profit; but our best kinds fail, as both fruit and foliage are liable to be attacked by mildew.

Propagation.

This is accomplished by seeds, cuttings, layers, or suckers.* The seeds should be taken from perfectly ripe fruit of the best flavour; they must be washed and dried, and then be sown in square pans filled with sandy loam mixed with leaf mould, or in the open ground in good soil. About May the young plants may be pricked out in rows a few inches apart; but, if not very forward, it is better to delay transplanting them until the following autumn. The seedlings generally bear fruit about the third or fourth year. Propagation by cuttings is the usual mode, and is performed in autumn, winter, or spring; strong, straight, one-year-old, thoroughly-ripened shoots should always be chosen. When the bushes are pruned, the wood should be selected, and every variety tied up and labelled separately. Each bundle must then be laid in the ground, with a little soil over the lower end, to keep the shoots fresh, until it is convenient to put in the cuttings. I prefer doing this about the middle or end of March; if planted out in the winter, they make little or no progress. Any spare corner is suitable for the cuttings. In making them, the bottom end must be cut clean through with a sharp knife or a pair of pruning-scissors. The buds should be taken out for 6 inches from the base; the spines may be left on, as they assist in keeping the cuttings firm in the ground. When the buds have been removed for 6 inches, 4 or 5 inches may be passed over, and the remainder of the shoot cut away; this leaves the entire cutting 12 inches long. The ground having been carefully dug over, the plants may be put in in rows 1 foot apart, 6 inches between each plant, and 3 inches of the stem below the ground, the soil being firmly pressed round each. During the summer, an occasional hoeing is required to keep the ground free from weeds. Layering long shoots or side branches is a quick way of getting a large plant. Soon after the bush comes into leaf, the lower branches, which it is desired to layer, should have a slice, an inch or two long, taken off their under side, near the part which is most convenient to rest on the ground, a strong wooden peg being placed over the branch and driven into the ground, so as to keep the cut part constantly close to the earth. Soil to the depth of 5 or 6 inches is then put over and round the peg, to cover a few inches of the wood. The roots formed from the edges of the wood and branches, in the month of May, may have taken sufficient hold by autumn to be severed from the parent plant. They can be planted out anytime throughout the winter. When the branches are too far from the ground to be brought down to it, the soil must be raised up to meet the branch. Another method of layering is to cover the point of the shoot with soil, pressing it firmly enough to prevent its becoming displaced; roots are soon formed at the point of the shoots, and a bud immediately makes its appearance. This grows in the form of a sucker for some time, when

* New varieties can, of course, only be obtained from seed.

side-shoots are thrown out, and, like the other ones which have been layered, they may be cut away and planted by themselves when the leaves are shed. Propagation by suckers is considered objectionable, as the plants so obtained are apt to produce suckers. In a well-managed plantation there should be no suckers; but, in the case of scarce sorts, it may be advisable to encourage them for the sake of increase. They should be planted in autumn, and transplanted a year afterwards, on which occasion the roots, whilst out of the ground, ought to be closely examined and every bud completely removed. By a little care, good plants with clean stems may be formed; and, if the shoots and leaves are kept healthy and vigorous, the disposition to produce suckers will be easily overcome.

Pruning.

Success in Gooseberry culture depends much on pruning, an operation which is sadly neglected in many instances. It may be performed at any time from November until the end of March, or before the bushes come into leaf. It is desirable to keep the centre of the bush well open, and not to allow the shoots to cross. A symmetrical form should always be preserved; but it should be remembered that without a very thorough thinning-out, no fine fruit can be expected. As a general rule, it may be safely said that one-half of the head, including old and young branches (more especially the former, as the young wood bears the finest fruit) should be taken out, leaving a proper distribution of shoots throughout the bush, the head being sufficiently thinned to admit the light and air freely. The branches should be kept as nearly as possible at equal distances, and laterals cut back to one eye if weak, or two or three if strong. Shoots, which start up with greater vigour than the generality, ought to be stopped in summer, unless they are likely to be wanted to fill up a vacancy. When there is an equal degree of vigour in the respective branches, the tree will be more healthy than if some were allowed to be too weak, in consequence of others becoming too strong, and the fruit will also be finer flavoured.

Planting and General Culture.

The Gooseberry is not very particular as to soil or position; it, however, succeeds best in a deep rich soil. Previous to planting, the ground must be trenched to the depth of 2 feet, a layer of strong dung being placed at the bottom of each trench, and a quantity mixed in with the soil nearer the surface. As soon as the plants are becoming crowded in the propagating rows, they should be lifted and placed in the prepared ground. The planting had better be done in the quincunx form; and if the distance between the rows be 6 feet, that of the plants in the row will require to be 5 feet $2\frac{3}{4}$ inches. These are good medium distances; but in rich soil they may be increased, and in poor ground diminished. There will be a spare piece of ground between each row for some time; and, until this space is filled up, a row of Cabbages, Cauliflowers, or any other vegetable may be planted between each row. The fruit is best flavoured from an open situation; but it must be remembered that a liberal top-dressing of cow-dung, or other manure, should be forked in about the roots every year when pruning is performed. In small gardens, it is better to plant a row of Gooseberry bushes round each plot, and other fruit trees can be mixed here and there amongst them. In a cottage garden, a row of bushes may be planted on each side of the small walks. In some places, they are grown as pyramids, or trained against walls and trellises; but I never saw them more successful than as dwarf bushes.

Uses.

This fruit is, in the first place, a very important one in its green state, being in high estimation for tarts and puddings. A delicious pale jelly is also made from it. The earliest use of it appears to have been as a sauce with green goose, whence the name. In its ripe state, it is a very agreeable table fruit, following the season of Cherries. Unripe Gooseberries are bottled in water for winter use, placing the bottles when nearly filled a few moments in boiling water, afterwards corking and sealing them, and burying them in a cool cellar, with their necks downwards. As a luxury for the poor, Mr. Loudon considers this the most valuable of all fruits, "since

it can be grown in less space, under more unfavourable circumstances, and brought into bearing sooner than others." The Gooseberry forming, as it does, a most useful article of food, and from its cheapness within the reach of every one, deserves to be more generally cultivated in our rural districts.

Varieties.

The varieties in cultivation are very numerous, and most of them have some valuable peculiarity to recommend them. Many, however, are scarcely worth growing for general use. The principal thing in forming a plantation, of whatever size it may be, is to select kinds which come in one after the other in succession. There is very little difference in the periods of ripening; but, in order to extend the season, the late sorts should be planted in the more shaded parts of the garden. The following kinds are the most suitable for cultivation as regards size and flavour:

REDS.		GREENS.	
Size.	Flavour.	Size.	Flavour.
London	Aston	Shiner	Greengage
Dan's Mistake	Crown Bob	Thumper	Keepsake
Clayton	Farmer's Glory	Stockwell	Green Walnut
Conquering Hero	Sportsman	Telegraph	Greenwood
Speedwell	Rifleman	Matchless	Jolly Angler
Ploughboy	Lancashire Lad	Green London	Rattler
WHITES.		YELLOWS.	
Antagonist	Princess Royal	Katherina	Champagne
Careless	Whitesmith	Drill	Rumbullion
Overseer	Smiling Beauty	Leveller	Yellow Ball
Snowdrift	Queen Anne	Criterion	Yellow Sulphur
King of Trumps	Royal White	Leader	Cottage Girl
Hero of the Nile	Sheba's Queen	Trumpeter	Teazer

Enemies.

There are several species of insects which are very destructive to the Gooseberry. The *Abraxas grossulariata*, or Magpie Moth, deposits its eggs on the foliage, and from them is hatched, in September, a slightly hairy cream-coloured caterpillar, spotted with black, and marked with orange along the sides, and which forms a loop in walking. It feeds on the leaves in autumn and spring, devouring all but the petiole; and, after entirely defoliating both Gooseberry and Currant bushes, it changes into a pupa in May or June, and in about three weeks afterwards the perfect insect makes its appearance. Hand-picking the caterpillars at an early stage of their growth, and, still better, burning the leaves on which the eggs are laid, are the troublesome means by which this destructive pest may be got rid of. Pouring over the bushes ammoniacal liquor diluted with water is stated by the late Mr. D. Beaton to be the easiest mode of destroying the caterpillars; but the strength of the liquor varies greatly; it is, therefore, advisable to ascertain, by experiment, the least amount of diluted liquor that may, without injury, be applied during sunshine to the leaves of some useless plant with tender foliage, and then add as much water as will ensure the safety of the Gooseberry leaves, without rendering the application too weak for the destruction of the insect. Another destructive insect is the caterpillar of *Phalœna vauaria*. It is about an inch in length, of a bluish-green colour, dotted with black tubercles, has ten legs, and, like the caterpillar of the Magpie Moth, forms a loop in walking. It changes into a pupa towards the latter end of May, and the perfect insect appears in the following month, or in July. Hand-picking, as soon as the larvæ are perceived, and dusting the bushes with hellebore powder, or with lime, are the means usually employed for its destruction; and, as the insect undergoes all its transformations on the ground, scattering newly-slaked lime around the bushes when the caterpillars quit is, perhaps, the best means of preventing the repetition of the mischief in the following year. The Gooseberry and Currant Saw-fly (*Nematus Ribesii*) deposits its eggs on the under surface of the leaf, by the side of the principal nervures, early in spring, and successive broods of flies appear until October. The larvæ devour the leaves, leaving only the petiole; and, when full grown, which is the case when they are about three-quarters of an inch in length, descend to the earth, spin a cocoon, and change into pupæ, from which another brood of flies soon emerges. Burning the leaves upon which the eggs are laid, and hand-picking where the plantation is not very

extensive, syringing the bushes, and then dusting them with lime, which should also be scattered round the stems, and sprinkling the leaves with lime-water, are the remedies usually adopted. Removing early in spring the soil from round the bushes to the depth of 3 or 4 inches, and burying it in deep trenches, in order to entomb the pupæ, is a good preventive measure. Syringing the bushes in the evening, and sprinkling them with salt or soot, as well as flowers of sulphur applied with a sulphurator, are likewise said to be infallible remedies. In addition to the formidable enemies above enumerated, birds frequently prove very destructive, by picking out the buds in spring. The remedy which succeeds the best with me is, immediately after pruning, to pass threads of white worsted, which need not be close together, a few times over the trees, winding them in and out of the branches. This effectually frightens the birds, who never attack trees so protected.

M.

Shading Pines.—Shading during strong sunshine may be, as Mr. Barnes says (see p. 294), an old-fashioned practice, but it is also a very general one, and is regarded as a means of securing perfectly developed fruit and foliage. In six different Pine-growing establishments with which I have been connected, shading was put on to keep the foliage fresh and succulent instead of scorched and leathery. Pine leaves are always tender after a winter's confinement in a close house or pit, and when strong sunshine is allowed to strike them before they are inured to it, scorching is frequently the result, and, therefore, the plants experience a serious check. Where shading is practised, it should be put on early in the season, and not about midsummer, when the mischief is done. I have often seen exposed crowns of large fruit burnt brown by the sun's rays in May, and it is no uncommon occurrence for fruit thus exposed to be ripened prematurely, at least its upper portion, while the lower half, which is more shaded by the leaves, is still green. The side most exposed is also subject to become partially broiled, an evil which shading prevents. I have seen larger fruit ripened in the shade than ever I have seen fully exposed to the sun. In recommending shading "by and by," I did not intend that light should be excluded; on the contrary, I only meant that the power of the fiercest rays should be broken. It would be difficult to manage an unshaded Pine pit during a hot summer's day when the outside temperature was above 100°. The fine specimens of Pines ripened under thick rough-rolled plate glass shows that black-heartedness is in no way connected with shading. Pine-apples differ greatly from such fruit as Peaches, Figs, Cherries, and Plums. These would be flavourless matured during the dull months of winter, but Pines attain as great perfection in this respect in the darkest months of the year as in those that are brightest. Shading, therefore, though antiquated, benefits rather than injures Pines.—J. MUIR.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Fruit Prospects.—A marvellous crop of Apricots has set on trees on my cottage, and the Peach wall is literally a sheet of rosy-pink bloom. Cold as the weather is, it is better for fruit trees than warm clear days and white frosts at night. Apples, Pears, Plums, and, indeed, all hardy fruits are full of promise.—A. D.

How to Improve the Flavour of Strawberries.—Just now we are putting ripe Strawberries into cold houses to cool and improve their flavour. Before any are gathered we go over them and into all the best pots stick small pegs. These we breed from for next year's forcing—and thus our stock does not degenerate, but improves by means of judicious selection.—R. GILBERT.

Thinning Hardy Fruits.—This year there is a great show of fruit, and if the blossoms escape destruction by spring frosts, there seems every likelihood of the trees setting heavy crops. Where such happens it will pay to go over them—Apples, Pears, Plums, &c.—and thin the fruit out, leaving, however, a good average crop; all the deformed and smallest fruits ought to be taken off. Not only will the fruits left be better in quality for being thinned, but the chances of as good a crop next year will be greater.—R. P. B.

Bloom Shedding in Forced Peach Trees.—I have Royal George and Newington both under glass, but, while the Royal George has set almost all its flowers, on the Newington not one has set. Both are of the same age and size, and each covers about 100 square feet. Last year the Royal George produced seven dozen well-finished fruit, while on the Newington there was not one dozen, although both made good clean growth during the summer which was well ripened. I shut up the house on the 9th of January, but used no fire heat until about the first week in February (the weather in January being extremely mild) and air was left on night and day. I can safely say that from starting them to the time when the Royal George was set, the temperature was never higher than 45° (with fire heat) or lower than 40° at night. I gave the house a good soaking with water at starting, and both trees were completely covered with bloom. In order to assist the setting I applied the camel-hair brush occasionally when the sun was shining. Both trees are making good clean growth; the border is inside the house. The Royal George is thickly set with fruit at present as large as marbles. Is the Newington a bad setter, or not adapted for house culture.—R. H.

RAVINE VEGETATION.

FROM a bridge spanning a ravine, as in the case of the annexed illustration, inviting, as it does, quiet contemplation, we are often enabled to discern minor objects of beauty which, under ordinary circumstances, would be passed by unheeded. Here a charming tuft of Moss covered with hundreds of its classical urn-shaped capsules supported on shining foot-stalks; there a tiny bit of Wall Rue embedded between the Lichen-covered stones—stunted it may be, but, nevertheless, happy and at home. A bit of the Maiden-hair Spleenwort peeping out from beneath the archway appears to express in the language, if not of flowers at least of Ferns, a desire to be more closely inspected. Well I remember once in a wild mountain tarn responding to such an invitation, and being rewarded by a glimpse of loveliness as regards Fern growth that, but for the pause in the ramble invited by the bridge and the supplementary invitation from the frondlets beneath, would have been overlooked. Rarely, indeed, has a closer inspection failed to reveal something unexpected—some little treasure that might be taken home as a special souvenir. The impressive grandeur of the rocks in the case now under consideration, piled in irregular jutting masses—here all but overarching the narrow stream, there anon expanding outward into a sort of graduated series of irregular and abrupt terraces, associated and contrasted with the finely developed fronds of the Ferns—could not fail to enchant all lovers of the romantic. Under the subdued light—moistened by the trickling drops that filter through the rocky crevices, and sheltered from the drying winds—many of our most charming plants find a fitting and congenial home, in which they frequently enjoy a magnitude of development that almost leads one to question their specific identity. What lovely masses of Moss festoon the face of the jutting rocks!—and, deep beneath, in the dark corners, creeps the Marchantia, and other Lichens, stealthily but surely performing their own infinitesimal part in the gigantic work of disintegration that is continuously in progress. Then, again, what an additional interest do the tortuous roots give rise to as they twist and twine in search of their scanty food, inserting themselves into every crack and crevice, and gradually growing in thickness, till they become gnarled with age, and in their growth assert the vital power of organic over inorganic Nature by displacing, at times, large fragments of rock into the stream below. Seeing then that these ravines have an especial beauty, and constitute a marked characteristic in our natural scenery, the question suggests itself—or ought to suggest itself—to every possessor of a garden, Is there any wild corner that could, by a little skilful manipulation, be metamorphosed into a ravine? The question once put and fairly thought over will, I venture to say, in a large majority of instances, receive an affirmative reply. It has been my lot to extemporise more than one, and in every case I have availed myself of an out-of-the-way corner, overgrown with Nettles, and previously a receptacle for nothing better than rubbish. Any attempt to imitate Nature on a large scale must necessarily be attended with considerable expense in the matter of labour alone, independently of the cost of massive blocks of rock, old roots, &c.; but there are gardens in which Nature has provided the necessary elements to form the groundwork, and it may not be out of place here to give a few hints by which the amateur may be assisted in the selection of such plants as are best adapted for beautifying the groundwork already formed to his hand. Where such a ravine is traversed by a stream and overshadowed by trees, few plants are more at home than the great majority of our hardy Ferns. Chief amongst them I would recommend the Royal Fern (*Osmunda regalis*) and the various other North American species—*O. cinnamomea*, *interrupta*, and *Claytoniana*; the delicate fronded *Onoclea sensibilis*, and the ostrich-plumed *Struthiopteris pennsylvanica* and *germanica*. The Oak-leaved Polypody (*Polypodium dryopteris*), whose delicate fronds are so susceptible of injury from dry winds and bright sunshine, should have a shady nook well supplied with leaf soil, wherein its slender underground stems may ramble freely. Should there be a trickling rill, as is not unfrequently the case, contributing its portion to the stream below, a little cave may be easily extemporised, wherein masses of the Filmy Ferns may readily be established, by simply attach-

A RAVINE NEAR SORRENTO.

ing them at the top between the crevices of the rock, and allowing them to hang down on the perpendicular face of any soft sandstone, to which their roots will in a short time adhere closely. In the bottom may be placed a plant of even the Killarney Fern, which, provided a regular state of atmospheric moisture can be maintained, will, under conditions such as these, flourish admirably. As creeping plants for covering damp soil and forming natural draperies, none are better than the common Moneywort, *Lysimachia nummularia* and its golden-leaved variety; also *L. nemorum*, whose yellow blossoms are very beautiful; and the *Sibthorpia europæa*, of which the advent of a handsome white-edged variety was alluded to in a recent number of THE GARDEN. The Golden Saxifrage (*Chrysosplenium oppositifolium*) dearly loves a damp locality. Associated with these there are many varieties of the common Ivy, all of which are equally happy in shade and sunshine. The Wood Anemone and the wild *Oxalis acetosella*, with the rarer *Paris quadrifolia*, and all the *Trilliums*, are well adapted for such a purpose. The several species of *Epimediums*, such as *pinnatum*, *violaceum*, *macranthum*, and even our common *alpinum*, are alike beautiful in their bloom and in the exquisite delicacy of their leaves when protected from the sunshine and east winds; but an abundant supply of good decayed leaf soil is always essential for them, failing which their growth will be unsatisfactory. As to shrubs and plants of a larger growth, our field of selection is somewhat more limited. The Spurge Laurels, both *pontica* and *laureola*, are grateful alike to the senses of sight and smell. Some of the smaller Bamboos from Japan and the Himalayas may be introduced at prominent parts with good effect; but where the overhanging wood is very dense, their place may be occupied by our giant and graceful Sedge Grass—*Carex pendula*—with handsome broad foliage and long pendent spikes of fruit, which it retains for a considerable time. The various species of giant-growing Angelicas, such as *atro-purpurea*, *decurrens*, and *lucida*, if given plenty of rich soil, will grow with a vigour and to a size quite surprising. Equally well adapted for the purpose is the rarer *Molopospermum cicutarium*, whose handsome sharply-cut leaves are equal in beauty to any of our Ferns. High amongst the rocks the fleshy root of the Black Bryony may be inserted, and, if it does not produce its beautiful scarlet berries, it will, at least, present graceful festoons of bright heart-shaped leaves, and, in the wild elegance of its growth, lend an additional charm to the scene.

J. C. NIVEN.

Botanic Garden, Hull.

Professor Asa Gray on Vegetable Mould.—Sometimes practice and science seem to be at variance; but, after a while, they make it up and come to a good understanding. Practice has always said that vegetable mould was a good thing to have in the soil, and that, somehow or other, plants obtain a great deal of nitrogenous nourishment from it. The proof of it was in the crops. The gardener thought the same, and his pot-plants gave convincing evidence of it. He has gone on saving his leaf-mould, and gathering it where he could, and putting his plants in it all the same; while the chemists were proving, to their satisfaction, that humus did not amount to much, and even have “seemed to prove that the fertile garden soil has little, if any, more power than so much sand to supply plants with nitrogen.” They could not find that the combined nitrogen ever got into the form of ammonia or nitrates. At last, says Dr. Gray in the “*American Agriculturist*,” it has occurred to one of the chemists, of a practical turn of mind, to test the matter by growing plants in pots, in the gardener’s way, supplying them with different quantities of vegetable mould, and withholding it from others of the same sorts, and then chemically analysing the plant to see what it had got. This has been done by Professor Storer, and a full account of the result will be found in the last (third) part of the “*Bulletin*” of the Bussey institution. Vegetable mould, especially in cool climates, where it most accumulates, and where also it is more useful than in warm climates, is a store that Nature has been an immense while in gathering, and which it costs nothing to use. Now, after hearing it depreciated by the chemists of late years, it is pleasant to see one of them come to the conclusion:—“There can be little doubt that, for the present support of agricultural crops, the vast stores of vegetable mould that have accumulated in the soil through the decay of many generations of plants, constitute a more abundant and more important source of nitrogenised plant-food than any other.”

GARDENING FOR THE WEEK.

Trees and Shrubs.

Transplanting Evergreens.—It will now be necessary to push forward the transplanting of these as vigorously as possible. Operate first on those that are most advanced; Hollies, Yews, and the majority of the *Coniferae* that make their growth later, may be left till the end of the month, as the season is a late one, and most shrubs are very backward. The longer Hollies are left, provided they are transplanted before growth actually commences, the more certain they are to succeed. The thing is to catch them just as they are on the move, and before the wood buds burst, as then they form roots very rapidly, through the impulse given by the growth of young wood and leaves. In removing valuable plants, the state of the atmosphere should be watched, and, if possible, a dull damp day for the operation chosen. This is the more necessary if the plants have to be carried any distance, as a dry state of the atmosphere would cause them to flag, and the tender roots would be liable to injury if allowed to get at all dry. It is of the greatest importance, therefore, that the plants should not be kept out of the ground longer than is absolutely necessary for their removal from place to place. When there are large numbers to transplant, the men engaged at the work may with advantage be divided into two gangs, the one in digging and preparing the holes, planting, watering, &c., while the others are engaged in lifting and forwarding the plants. In this way, the work can be carried on rapidly, and large numbers may soon be disposed of. Before filling-in, see that the soil is well washed among the roots, and allow all to settle for a night or so before finally filling up with dry soil. This will prevent the moisture from escaping, and keep the roots in a much more favourable condition than if they had been entirely covered in before watering. Indeed this is a bad practice, as the soil is sure to crack open, and let in large volumes of dry air that soon absorbs all the water that may have been given at the time of planting. To prevent this, and to keep the roots in a generally uniform state, they should receive a good mulching of half-rotten litter. The importance of this to newly-planted trees and shrubs cannot be over-rated; and I would urge on all engaged in planting not to neglect this necessary precaution if they would ensure success. Before attempting to remove and replant large fully-developed evergreens that have been standing a long time in the same situation, they must be well headed back, as the tops will be out of all proportion to the limited quantity of fibrous roots they can be taken up with. They need not necessarily be denuded of all branches and leaves, as, in heading back, the smaller shoots and sprays can be left; but nothing will be gained by leaving the large stems with a heavy weight of foliage that will make a larger demand on the plant than the mutilated roots will be able to supply. Stumps of plants may appear unsightly objects at the time, but they quickly break into growth at this season, and are sure to succeed; whereas, if removed with large heads, they would be hovering between life and death, and covered with unsightly brown leaves. Even if they survived they would not make such satisfactory plants as they do after heading down.

Pruning Evergreens.—Laurels, Evergreen Oaks, &c., that are required as screens to shut out buildings or any unsightly objects, may now be freely thinned out. A good many of the large branches may be entirely removed, so as to admit plenty of light and air to the lower part of the tree. By so doing, and shortening back the remaining stems, they will be found to break freely into growth below, thus forming plenty of foliage low down where required. A little timely thinning, and keeping the tops open, will prevent them from drawing up naked, and ensure the fulfilment of the purpose for which they were intended. Shrubberies, in like manner, soon become a wilderness of growth, if not looked after, and kept properly thinned, and choice plants are soon overgrown and spoiled by common free-growing varieties. Every plant should stand in a clear space, and any that are found to be encroaching or injuring the others, either by immediate contact or shade, should be at once cut back or removed. Such plants as common and Portugal Laurel may be headed back to within a yard or so of the ground, and these will form dense plants for removal another year. In pruning back others, it is necessary that it should be done with care and judgment, avoiding all stiff, formal shapes. Plants, of whatever kind, should be allowed to assume their own natural forms, as in this state they are generally far more pleasing. The pruning, therefore, should be done with the view to assist them in maintaining a natural, easy form of growth, which may generally be done by simply removing any loose straggling branches that are unduly taking the lead. Hollies generally assume the pyramidal form, and these and *Coniferae* should be looked to at this season, to see if there are rival leaders contending for the mastery. Should this be the case, the best situated for forming a fresh lead should be selected and all others removed without unnecessary delay.

Seed-sowing and Layering.—Haws of Thorns and Holly berries that have been buried in sand or other material for the last year should now be sown in beds prepared for this purpose. The seeds of Larch, and the different varieties of Coniferæ, as well as Alder, Birch, Chestnut, and other deciduous trees, should be sown in like manner. The beds for this purpose are most convenient for cleaning, if made about 3 feet wide; and, as to the length, that must be determined by the quantity to be sown. The soil of the beds should be removed to the depth of an inch or two, more or less, according to the size of the seed to be sown. Such large seeds as Chestnut should be covered to the depth of 3 inches, and Beech, Coniferæ, &c., in the same proportion, according to the size of the seed, but an inch or so may be stated as about the average depth to sow most of these. It should, however, be borne in mind that the larger the seed of any kind of plant the deeper will it be necessary to sow it, and *vice versa*. After sowing thinly and regularly over the surface, the soil raked off the beds previous to sowing should then be scattered evenly over the seed, and afterwards carefully raked level. The alleys should then be neatly marked out in the usual way. To prevent birds from pulling up and destroying the plants just as they are pushing through, it will be necessary to net them securely over; the beds must be closely watched, to prevent the depredations of mice or rats; for, should either of these destructive pests find them out, they will soon make sad havoc amongst the seed. Any young plants standing in the seed-beds should now be pricked out, in rows, about 6 inches apart, and others that have been previously treated in this way should be planted out in nursery rows, about a foot asunder. All young plants except deciduous kinds, that are standing in the nursery to gain size, should be dug up and replanted, so as to induce plenty of fibre, and prepare them for future safe removal. Layers of evergreens, that were operated on at this time last year, should now be examined, to see if they have made sufficient roots to warrant their being severed from the parent plant. If so, they should be at once removed, and planted in the nursery, or other convenient sheltered place, to make a season's growth, and their places may then be occupied with fresh layers. Before layering, the branches should receive a slight twist, so as to accelerate the formation of roots, and may then be pegged securely down, and covered with 3 or 4 inches of soil. Clematises root very readily in this way; and, where it is desirable to increase the stock of these, spare branches should be laid in at once. These have been much improved of late, and are a very showy free-blooming class of plants, suitable in many positions for garden decoration, especially for trellises, sloping banks, &c. *Lanuginosa* is still one of the handsomest, and should be in every garden. —J. SHEPPARD, *Woolverstone*.

Indoor Fruit Department.

Vines.—Insects are liable to make their appearance in Vineries as the hot weather advances, for heat and fresh air seem to favour their development as well as that of the Vine. Red spider is frequently a very troublesome pest, and when once established it is difficult to eradicate. If it appears on the Vines at an early stage of their growth it is certain to do a great deal of harm before the wood and fruit are matured, and it is best to use every endeavour to prevent it, if possible, from gaining any footing at all. This can generally be accomplished by giving the Vines a thorough syringing once a day with clean water, an operation which should be continued up to the time colouring begins. A sweet, humid atmosphere, and a consistent state of damp at the roots, assists greatly in keeping it down. Indications of its presence are shown by the leaves on the lower side becoming somewhat dingy or brown. It requires careful examination to see them where only a few exist. As their number increases delicate webs are run from vein to vein on the back of the leaf, and they are then more easily seen. From here they go on to the bunches and the old wood so that every part of the Vine must be syringed to penetrate into their hiding places. Insecticides of various kinds are often tried for destroying these pests. In many instances they are too late in being applied to be of much service, for, to be effectual, they should be used more as a preventive than as a cure. Thrips is another miniature Vine pest, capable of doing a considerable amount of evil, that usually accompanies the preceding. It is larger in body than the spider, but somewhat long and very slender. The young are white, and the old black, in colour, and they fly from one place to another. Their favourite resorts are the points of young fresh-growing shoots; they eat small holes in the tender leaves, and some parts become almost transparent where they have been at work. The growth of the part which they attack is generally arrested, and this assumes an unhealthy appearance. Syringing is of some use, but to exterminate them the house in which they are must be fumigated with tobacco smoke for two or three evenings in succession; the house should be filled until the smoke is so dense that the hand cannot be seen at a distance of 2 feet from the eyes. A washing

with the syringe or garden engine should be given to the leaves after the fumigation is discontinued. Mealy bug, when established, is one of the worst insects to clean from Vines. Little or nothing can be done towards its destruction while the Vines are in leaf. A look-out should be kept for it throughout the growing season, and the Vine marked, wherever it is seen, for cleansing when the Vines are pruned and dressed. These remarks apply to young Vines in pots as well as old established fruiting ones, none of them are exempt from their intrusions, but are all generally liable to their ravages. *Phylloxera vastatrix* might be mentioned in addition to these enemies; but the comprehensive descriptions of it already given in *THE GARDEN* render more than a passing allusion to it unnecessary.

Pines.—Whilst insects infest the wood and leaves of many plants, the Pine is all but vermin proof. When care is taken not to place any other plant near them years may elapse before a single insect is seen upon one of them. Stove plants are sometimes set about spare corners in the Pinery, and in such cases bug and scale are not slow to change their quarters. It is very difficult to remove the bug from amongst the foliage, especially if it finds its way down about the base of the leaves. It is preferable to destroy a few plants to get rid of it, if the others are clean, rather than keep all and have the whole infested. Small suckers may be washed with a brush and soap and water, when they are taken from the plant and before they are transferred to their sucker-pots. Brown scale is an enemy common to many Pines. Its presence appears to do little or no harm, and it is more inclined to attach itself at the apex than further down the leaves. It may be brushed off; and, if the plant be dipped into water heated to 130°, the scale will not survive. The white scale is more destructive than the other, and is considered the worst pest which affects the Pine. It eats the leaves, and has a very enervating influence on the plant. It multiplies fast, and spreads to every nook and corner to which it can get the slightest access in a very short time. The remedy recommended for the brown scale will do much towards keeping the white kind in check. Where this fails it is doubtful if the house will be perfectly clean until an entirely new stock is introduced. —J. MUIR.

Peaches.—Where Peaches have stoned, the houses may be kept warmer and the moisture increased, so as to push on the second swelling of the fruit; this is the period when lost time can safely be made up by extra forcing if ripe fruit is wanted by an early date. The trees should be gently syringed early in the morning and about three o'clock in the afternoon, the houses being shut up with a temperature of 80° during bright weather. With the sun early on the glass, ventilation must be seen to in good time, or the heat will be too strong at the apex of the house, and will damage the foliage. A good watering may now be given with guano-water or other liquid manure, or the manure may be spread on the border and washed in by watering, which must be done thoroughly, as the want of sufficient moisture will cause the fruit to look pinched, and finally to drop off; it will also sometimes cause the fruit to gum at the second swelling, disfiguring it, and totally spoiling its appearance for dessert. In houses where the stoning process is in progress, a steady equable temperature must be maintained, with plenty of air. No attempt at pushing the trees at this period must be indulged in, and care must be taken that the number of fruits is not in excess of the capabilities of the trees to mature them thoroughly. Trees that are overtaxed this year may show it the next season by refusing to yield a crop. One fruit to every square foot of surface is plenty in the earliest house, but more may be allowed in later houses. Early York is still our best early Peach; Royal George and Noblesse, in the same house, are equally good, though a shade later; whilst *Violette Hâtive* is the most forward Nectarine. Attention may be given to pinching and training in the young wood in early houses, overcrowding being avoided. It is not necessary to be rigidly particular in "tying in" early; the growth may be allowed considerable freedom for a time while the fruit is swelling, but should be tied down before the ripening period, so that the rays of the sun upon the ripening fruit may not be obstructed. No more spray should be allowed to grow than is absolutely necessary. The weather has been highly favourable for setting the fruit in unheated houses, and the syringe may now be freely used during all fine mornings. Disbudding will also require attention, and if small colonies of black aphides should make their appearance in places, and it is not thought worth the expenditure of tobacco to thoroughly smoke the houses, a few puffs of Pooley's tobacco powder will be found effectual for a time; it should be applied after the trees have been syringed. Although it is not so effectual a remedy for fly as fumigation, it is the safer one while the young foliage and fruit is still tender. The set of fruit in cool houses have been remarkably rapid this season, the first anthers which burst being sufficient in each flower to fertilise the future fruit, the rest of the anthers withering immediately, and not bursting at all; this we attribute to

the very favourable weather. Proceed to thin the young fruit in good time, and do not waste the energies of the trees upon a mass of useless fruit grown to the size of Peas before they are thinned out.

Melons.—We do not wait for a full crop of fruit to set on the earliest Melon plants, but are content with two or three on each to begin with, and when these have half swelled more will set in abundance. It will be necessary to impregnate by hand the blossoms in the earliest house, choosing the middle of the day when ventilation is active, though the process may be equally effective in the morning or afternoon, even when the house is saturated with steam, provided the flowers are not actually wet with water. See that there be no lack of moisture at the root, especially when fruit is swelling, as dryness will be the sure forerunner of red spider, and of badly swelled and badly flavoured fruit. Do not unnecessarily wet the necks of the plants at the surface of the soil; a pot split into two halves, which are inverted and placed round the stem of the plant so that it comes through the hole of the pot, will be found a good safeguard against wet from the syringe or heavy watering. A succession should now be planted, and more plants raised from seed to fill up pits by-and-bye, when bedding plants have been removed.—W. D. C.

Flower Garden and Pleasure Grounds.

The weather, during the months of February and March, was much colder than it was during January, consequently spring flowers, as well as vegetation generally, has been more backward than is usually the case. Various kinds of early-flowering plants and spring bulbs are now, however, in full beauty, and others will be in equally good condition before long, and should, therefore, have every necessary attention, as the time during which such plants can be allowed to occupy the flower beds must this season be short. In cases where the flower beds are unoccupied, and where it may be intended to use hardy plants for the purpose of forming edgings and divisional lines, this may be attended to now, or as soon as the beds have been properly enriched by the addition of fresh soil or manure, as it is an advantage to get such plants somewhat established before very warm or dry weather sets in. Such plants may consist of the *Cerastium tomentosum*, *Santolina incana*, variegated *Euonymus radicans*, *Veronica incana*, *Stachys lanata*, and several other species of hardy plants, remarkable on account of their foliage, together with such succulent plants as the well-known *Sempervivum californicum*; also the useful *Echeveria secunda glauca*, which may now be safely planted out, as it is nearly, although not altogether hardy. If the stock of *Stellaria graminea aurea* is insufficient it may still be increased by means of division or cuttings; this is a useful plant for carpet bedding, and will probably be found to form a better companion for the various *Alternantheras* than even the Golden Feather *Pyrethrum*. Hardy herbaceous plants on the margins of shrubberies, and elsewhere, and Alpine plants on rock-work, will now be interesting, and should have whatever attention they may require, such as filling up any vacancies which may exist; and provision for this should always be ensured by wintering a few plants of each variety—or, at least, of the most choice species—in pits or frames. The soil in which such plants are growing should also be enriched and slightly forked up, and the dimensions of plants which may have become too large should be reduced. Many kinds of hardy trees and shrubs are usually increased by “layering,” and the present is a suitable time for the performance of such operations, which should receive early attention in order to give the layers as long a season as possible for the formation of roots. This operation should be performed in much the same manner as that practised in the case of Carnations and Picotees—viz., cutting a sort of tongue with a sharp knife, on the under side of the branch, at the part intended to be inserted in the soil. Let the knife enter the branch to the depth of about one-half its thickness, and cut from the base upwards for about 2 or 3 inches; in the slit-up portion of the branch insert a small wedge, or piece of stone, to keep it open; fix this part firmly in the soil, and keep it in position by means of a strong peg. Such layers will generally form abundance of roots during the ensuing summer, and, in some instances, they may be found sufficiently rooted to be separated from the stools during the succeeding spring, when they should be trimmed and planted in nursery lines, where, with proper attention, they will soon become well-formed plants. The presence of sufficient roots, or otherwise, however, should always be ascertained before severance from the stool takes place. Take off cuttings of Dahlias, pot them in small pots, and place them in a hot bed until they are fairly rooted, when they should be gradually hardened off, along with other kinds of bedding plants. Continue to prick into pans or boxes the young seedling plants of the various blue Lobelias, and the Golden Feather *Pyrethrum*. Old plants of this useful bedding plant need never be saved, unless for the purpose of producing seed, as seedlings are best for all purposes. Plants intended for furnishing vases and baskets

during the summer, in the flower garden or elsewhere, should now be shifted into larger pots, so as to have them of sufficient size to produce an immediate effect when the season arrives for placing them in the open air. The various kinds of Zonal or bedding Pelargoniums are mostly used for this purpose, and with good effect, as they generally produce a great abundance of bloom. Such plants as the *Fuchsia fulgens* are also well suited to this purpose. The most graceful and appropriate plants for vases, however, are those with sword-like leaves, such as the Aloes, *Dracænas*, *Yuccas*, *Tritonias*, the New Zealand Flax, and *Agapanthus umbellatus*. Plants of a trailing habit of growth should be planted round the margins, to hang over the sides; and, for this purpose, the Ivy and hybrid Ivy-leaved Pelargoniums are well suited, together with such plants as *Campanula fragilis*, *Convolvulus mauritanicus*, and blue Lobelias.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

See that all Rose trees are properly staked and trained before they get too far-advanced into growth, as the heavy winds during this month often do great damage to the young shoots where they are not carefully trained. The season for Rose tying and training is now advancing; great care must be taken not to rub or break off the buds of last summer's budding, and slightly protect all tender varieties. Look carefully over all trees, as the caterpillar will, in warm gardens, be found to have attacked the buds when these have advanced far into growth, and Roses require carefully looking over every week, to keep down such pests at this season of the year. Prune all late-planted Roses very close, as they are more likely to break and flower well than when left with long shoots to form a large head. In some gardens more than others, the Roses get much covered with Moss. In that case, it is advisable on a dry day to have it well cleaned off, which may be done easily by hand-rubbing. Then wash the stems over with some soap-suds, mixing some soot with the water. This will be found quite sufficient to kill all Moss, and will in no way injure the tree, but give the stems a perfectly healthy appearance.—H. G.

Kitchen Garden.

This is a good time for making a full sowing of the various kinds of Broccoli and Winter Greens to succeed those sown earlier. All early sown plants should, of course, be transplanted. To sow early, with a view to having a long growing season and perfect development, and then allow the plants to remain starving in the seed-bed, is worse than useless, and I do not wonder at anyone who adopts this method complaining about their bare and spindly habit. Many a suggestion, good in itself, is condemned through being imperfectly understood or carelessly carried out. Few, I suppose, will deny the advantages of transplanting Broccoli and other plants of a similar nature from the seed bed for a few weeks before being finally planted out. Overcrowding, when young, has the same debilitating influence upon plants as upon animals, only the lives of vegetables being generally of shorter duration the effect, perhaps, is not so apparent. I know it is only by the greatest exertions that the ordinary garden operations can be accomplished, especially at this season of the year, and some things that may be considered very necessary cannot always be carried out from a severe pressure of other matters that must not be postponed, but an effort should, in all cases, be made to transplant the main portion of what are commonly called Winter Greens and Cauliflowers, to enable them to gather strength till the land is vacant to receive them finally. Salsafy and Scorzonera should also be now sown thinly in good deep land, in drills, about a foot apart. Chicory may also be sown shortly. This makes a useful salad plant, when forced and blanched in winter. Sow twice this month early spring Cauliflowers, to make sure of having plenty of plants to put out when required. Sow the Red-stone Turnip about every fortnight or three weeks; this will be found more satisfactory, especially in difficult places, than depending upon one large sowing. Covering with the charred refuse from the rubbish-heap, first passed through the sieve, has a wonderfully stimulating effect, and prevents the attacks of fly. I am so thoroughly impressed with the value of this that I have always a heap saved for covering all small seeds. Shift on Tomatoes to have large strong plants to put out about the end of next month; Capsicums may yet be sown in heat, and the early-sown plants pricked out and forwarded. Ridge Cucumbers may be sown in a gentle hotbed, but a strong heat is hardly necessary; a portion of the seeds may be reserved for sowing on the hills under hand-lights next month; such plants often do better than those nursed in heat, especially in modern days, when much room is taken up by bedding plants. After the rains of the past week it is probable the weeds will soon become troublesome, and no time should be lost in getting rid of them before they have made much head.—E. HOBDAY, *Ramsey Abbey*.

THE GARDEN IN THE HOUSE.

A PORTABLE AQUARIUM.

THE accompanying illustration represents a simple and useful little parlour aquarium, in which many small exotic aquatics and some of our native water-weeds will grow as well as in a contrivance of greater dimensions. It consists simply of a glass vessel, similar in shape to an ordinary bell-glass, but furnished with a stand, and covered either with another bell-glass or an ordinary glass shade. A handful of sandy soil or gravel and a few shells at the bottom serve to hold the roots of *Vallisneria*, *Aponogeton*, *Chara*, and other water plants. Soft water is best for filling the glass if it can be obtained, and one or two golden carp add brightness and life to such an arrangement, and give motion to the water. Aquatic plants, or such of them as will grow in a vase of small dimensions, very rarely produce flowers, and, in order to counteract this want of brilliancy, a

A Portable Aquarium.

vase of cut flowers may be introduced, as shown in our engraving, and they will last fresh and beautiful for a much longer time than when they are fully exposed to the gas or fire-heated atmosphere of the sitting-room.

B.

Bouquet Flowers.—The weekly supply of cut flowers and pot plants increases; indeed, anyone who pays a visit to Covent Garden Market will be well repaid for their trouble, as the spring flowers are, to my mind, much prettier in bouquets than those in bloom later in the season, and a goodly array of both hand and button-hole bouquets is just now exhibited for sale in the windows in the Central Arcade. Amongst other cut flowers obtainable may be enumerated the following:—Azaleas, Bouvardias, Camellias, Carnations, Cinerarias, Cyclamens, Daphnes, Deutzias, double Pelargoniums, Eucharis, Heaths, Fuchsias, Forget-me-nots, Gardenias, Heliotropes, Hyacinths, Lily of the Valley, Mignonette, Narcissus, Orchids, Pelargoniums, Primulas, Primroses, Roses, Snowdrops, Scillas, Spiræas, Stephanotis, Violets, white Lilacs, and others. Button-hole bouquets are mostly made of Bouvardias, Camellias, Gardenias, Lily of the Valley, and Scillas, with the addition of Ferns and other foliage, according to taste. A pretty hand-bouquet, which I saw last week, was composed of the following, viz., a white Camellia, four Gardenias, some bunches of Violets, White Lilac, Azaleas, Lily of the Valley, and light Ferns, a fringe of Ferns being formed round the edge, so as to rest lightly on the bouquet-paper. This bouquet would be anything but effective if subjected to artificial light, but during daylight is very pretty.—A. HASSARD, *Upper Norwood*.

ON ALLOTMENT GARDENS.

By RICHARD JEFFERIES.

An allotment is a small piece of land devoted simply to the growth of table vegetables, or other plants of a strictly utilitarian character. Almost all villages which are situated in the midst of an arable district have one or more fields entirely given up to labourers as allotments. These are allotments properly so called. But, ascending still higher, there are other allotments to be found in the outskirts of rural towns. These are often on land which is in the market for building purposes, and you may see a board offering "This eligible site for sale" affixed to a pole rising out of a plot of Potatoes. The same thing occurs in large cities, near their edges, where they blend with the country; only here the true allotment is frequently lost in the market garden. In many country places there are large tracts of land which have been left centuries ago as a gift to the adjoining town, or presented to it by the then monarch, in recompense of services rendered by the inhabitants. As a rule, perhaps, these tracts of common-land will be found to be pasture; but instances of arable fields do occur, and, in certain examples, these extend to hundreds of acres. The occupation and use of these allotments is vested in the burgesses or aldermen; and minute laws have been elaborated in the process of generations regulating their distribution among the inhabitants. Although these tracts of land are not commonly so considered, in point of fact they are really and truly allotments, and come within the discussion. They are allotments on a larger scale, and governed by a recognised code; and as they have been in existence time out of mind, the lessons to be learnt from them cannot be overlooked. In visiting and examining many allotments I came to the conclusion that, allowing for slight differences consequent upon position, there was a great similarity in each instance to others of the same class. In commencing this examination it seemed natural to begin with the gardens attached to the cottages, and which, in certain places, are little more than allotments—that is, used for purely utilitarian purposes. The greatest amount of variation existed as to the size of the garden. Some cottages had barely enough to grow a few boilings of early Potatoes, the cultivated ground consisting of a narrow edging in front of the dwelling, and separated from the road only by rude palings. The inhabitants of these somewhat unfortunate places were always eager and anxious to obtain an allotment, but could not always do so, even though they were willing to pay a fair price and to walk considerable distances to it. The reason was that the allotment field was only just sufficient in size to supply the wants of those cottagers who resided in the immediate neighbourhood, and worked upon the surrounding farm. These, of course, had the preference in the letting of the lots, and rarely could an outsider obtain a piece. These cottagers, either being squatters or really the owners of their houses, and thus independent, and perhaps sometimes disagreeable in the habits of their lives to the adjacent farmers, could not persuade them to allow a plot of ground to be broken up. The result of these untoward circumstances was, that the cottager had, in great part, to go without vegetables, or else to purchase them, which he was often unable to do from their scarcity and high price. A little further along a cottage would occur to which was attached a small garden, perhaps 20 yards long by 5 or 6 wide, taken, no doubt, years ago from the waste at the roadside.

Cottager's Fruit Trees.

This cottage being held on quit rent, and therefore practically a freehold, the labourer and his forefathers had dwelt on it for three generations, and their taste plainly displayed itself in the garden, which was crowded with fruit trees of all descriptions, for it is a characteristic of the labourer that he seems to possess a singular fancy for planting one at least of every kind of tree and shrub, so that these small patches often contain as many varieties as really large gardens. Here are Apple trees, generally of old, Crab-like, and now disused sorts; always Bullaces, for which the labourer has a special predilection—their rough, though not unpleasant acid, is, no doubt, exactly suited to a palate accustomed to a long dietary upon bacon and bread and cheese—Damsons, Pears, and a small black Plum, which is also a particular favourite, and even, in one or two instances, a Walnut tree and a Filbert bush. Gooseberry bushes, Currants, not so often Raspberries, all crowd the confined area, and injure by their roots and shade the growth of the table vegetable. These, too, are of the most varied character. The whole area would be barely large enough to grow sufficient Potatoes for the family; but, instead of being devoted to that purpose, it is split up into half-a-dozen tiny plots, containing at least two varieties of Potato (there must be variety), Peas, Kidney Beans, Broad Beans, Parsnips, Carrots, Onions, and a few Lettuces. The profits of such a garden entirely depend upon the fruit trees, which sometimes, in favourable seasons, will yield sufficient to pay the entire rent and leave something towards winter clothing. The produce of a single good Plum or Pear tree will

amount to as much as two pounds, and, as no care has been expended on the cultivation and production of the crop, it is looked upon as peculiarly remunerative. But these returns are singularly uncertain, and years may go by without a single penny of profit. From the Parsnips the housewife makes a wine, as also from the Gooseberries and Currants, and occasionally from the Elderberries, which grow in profusion upon the hedge which bounds the garden, and which, in nine cases out of ten, is of Elder. These home-made wines are looked upon with great favour by the labouring class. Sometimes a labourer, whose father was perhaps a carpenter or blacksmith, has possession of a real orchard, though a small one—a piece of enclosed ground entirely planted with fruit trees, Apple in the centre and Plum near the outside. This is, in good hands, a source of considerable revenue to him. Instances of this kind are not so rare as may be imagined. The fruit of these small orchards has not been selected with the care exercised in the gardens of the upper class; it is mostly rough and acid, but it finds a ready sale in rural districts. The farmsteads generally possess an orchard in counties and localities where the Apple will grow; but in most cases these orchards have been planted by a previous generation, and the trees are fast decaying, while the sorts are no better than those in the labourer's garden. The result of the custom of overcrowding their small gardens with so many varieties is, that the cottager is anxious to obtain a separate piece of ground, which he may devote entirely to Potatoes and Cabbage. Some of them have long narrow slips by the roadside, for which they pay quit rent; and these are in reality allotments, with the difference that they stand solitary. Here the labourer grows his stock of indispensable vegetables. The size of the allotment granted to labourers in the corners of arable fields varies almost in exact proportion to the richness of the soil. If the soil is good, the allotment is comparatively small; if it is poor, it is large in area, though nearly similar in productive power. Thus, on down land, where the soil is thin and lies on a substratum of chalk rubble, with layers of flint, these allotments on the outside of arable farms often extend to a quarter of an acre, and even in exceptional cases to more than this. The field set apart for allotments in a genuine agricultural village, where the larger area of land is arable, is not an interesting object to look at. It is always close to the road: this is absolutely necessary on account of communication. The fences are mere mounds; all hedges being kept shorn close so as not to harbour birds. The ordinary plan is to have a cart-track straight through the field, from which paths branch out on either hand leading to, and at the same time acting as divisions between the lots. In the early part of the year the field has a most varied and patchy aspect from the innumerable small squares of various vegetables, each with its different shade of green. In autumn and winter it is desolate and an eyesore, unless where the rule of the rental compels the occupier to keep their lands clear and to remove or properly stack the refuse. Our labourers are not picturesque at this their favourite work of allotment gardening. The costume is against it; especially that of the women. Women do a great deal of work upon these allotments. They can pick weeds and hoe nearly as well as men: these always, however, retain to themselves the conduct of the sowing. One of the finest allotment fields I know is part of the glebe land of the parish rector. The former rector, with a foresight and spirit that did him justice, gave up these 8 acres as an allotment field with the object of reclaiming his village, which at that time did not bear a very good character. The people were sparsely, ill-lodged, and without gardens. No better plan could possibly have been devised. It answered to perfection. It gave the labourers occupation in their idle evening hours, thereby keeping them out of the ale-house. The very children could come and help, and took an interest in the growth of the plants. The men had something to think about besides drinking and grumbling. Gradually the whole village grew morally healthy. When the good rector passed away, another took his place who continued this really good work. To this day the result may be seen. This parish has few paupers, fewer criminals, less idle discontented men than the surrounding districts. The great object to be sought in the distribution of allotment grounds is, that there should be sufficient in each case to grow on one-half of the plot Potatoes enough for the family, while the other half is sown with other vegetables, and, in fact, lies fallow. This is the same thing as a rotation of crops. That the allotment resembles a farm is a fact that must have ere now been apparent to the reader; but there follows an illustration still more pointed. This particular allotment-field, though it was well situated, and comprised some first-rate soil, was rather low, and retained too much water. The landlord determined to drain it, and he did so in the way which cannot but strike every one as singularly fair. He bought the drain-pipes as his share of the cost. The pipes were put in by labourers who were paid the usual price for this work. Then the amount of this labour was divided out amongst the various tenants of the allotment.

grounds, so that each paid a share in proportion to the size of his plot. The largest allotment was 48 perches; and there were holdings of allotments of 16, 20, 25 perches, &c. This is a purely agricultural contract, and forms a fair precedent as to what should be done under similar circumstances. On this allotment-field, as in all others where anything like order prevails, the fences are kept as low as possible, and no hedges or mounds are allowed—the division is simply a green footpath. It is surprising that the plan of thus turning a portion of the glebe-land into allotments has not been more generally followed. A readier means of encouraging industry, and doing an immense amount of practical good, could not be discovered.

Allotment Rules and Regulations.

The following code of regulations, in reference to allotments, has been in operation for thirty-five years, and may therefore claim to possess a title to serious consideration. In this case the allotment gardens are the property of the lord of the manor, and are situated in a small village, distant from any town, and entirely composed of an agricultural population. "Rules.—1. That the tenant shall hold his allotment, as a yearly tenant, from the day of , after the rate of 4d. per lug (or perch), free from all rates, tithes, and taxes. 2. That the rent shall be punctually paid by the tenant to the landlord, or his agent, on the 28th of September in each year; but, if that day happens to fall on Sunday, then on the day preceding. 3. That all parochial rates, tithes, and taxes shall be paid by the landlord. 4. That the tenant shall keep the bounds and fences which join or belong to his allotment in good repair, and shall not trespass upon any other land in going to or returning from his allotment, or in hauling any manure thereto, but shall use and keep the regular and appointed road to and from the same. 5. That the tenant shall cultivate his allotment by spade husbandry. 6. That, on the tenant removing his residence from the village, he shall no longer continue in the occupation of his allotment. 7. That, if the tenant shall be convicted of felony, of any breach of the game laws, or do or commit any act punishable by law, or shall wilfully trespass or encroach upon the land of another tenant, or underlet any part of his own allotment, or make default in the payment of his rent at the time above-mentioned, or fail to perform any of the foregoing conditions, he shall immediately forfeit his interest in the land, together with his crop upon the same; and the landlord, or his agent, shall be at full liberty to take possession thereof, and to enforce the payment of all rent then due by sale of the crop or otherwise, as in cases of rent in arrear." The practical nature of these rules is at once apparent, and forms their chief recommendation. Rules 3, 4, and 7 especially seem to contain enactments that must be included in any effective code that may be drawn up. The proportion of land allowed to each tenant appears to be 40 perches. The way in which the thing has worked may best be gathered from the owner's own words:—"I have no restriction as to rotation of crops, all my allotments are well cultivated, and, with about eighty here, I have never lost a rent, nor have I ever, in thirty-five years' experience, had occasion to dispossess a tenant for non-compliance with the rules. Potatoes, when the crop escapes disease, is the most profitable crop my people grow; but, as these require a change, they grow on one-half of their allotments usually. We are too distant here for any advantages of town requirements of (say) Cabbages, Carrots, &c. When Potatoes are not a failure, as has often of late years been the case, some have told me that their profits on their 40 poles, including all advantages, have returned them a profit of fifty shillings; but so far from a market for any produce, I believe this amount to be quite exceptional." This case, from its peculiar circumstances, is remarkably interesting, and throws much light upon what may be accomplished, even under every apparent disadvantage, when a desire to benefit the lower classes is combined with practical knowledge, and a firm, though light, governing hand. It illustrates particularly the great demand there is for allotment gardens, even in places where a pecuniary profit is not obtainable except under highly-favourable conditions. There is no market for vegetables, yet the allotments are sought after; and have been occupied for more than a generation. This conclusively proves that, in reckoning the advantages of the allotment system, the element of pecuniary profit must not be rated too highly, for the convenience and accommodation rendered by a constant supply of fresh vegetables is quite sufficient to repay both the rent and the labour expended on cultivation. The one great drawback to the utility of allotments in towns is found to be the constant petty thefts that are committed. Allotment gardens are peculiarly open to spoliation from the absence of fences and the nature of the crops grown, which cannot be identified as a rule. In a season when there happens to be a scarcity of green food, such as Cabbages, Carrots, Turnips, &c., a tenant who happens to have been fortunate, and has a fair share of these vegetables, is pretty certain to find them materially diminished during

the night. For this reason, some people have a predilection for planting Parsnips, whose roots take a firm hold of the earth, and are not easily stolen. Another unpleasantness which occupiers of allotment gardens in towns are always in dread of is the sale of the very ground under their feet for building purposes. Often the agreement upon which a tenant takes a garden is worded to the effect that such a sale shall be deemed an immediate termination of the letting, so that a tenant runs a chance of his crops being sacrificed to the inroads of bricks and mortar. Notwithstanding these drawbacks, there is a strong competition for allotments in all towns; and the difficulty experienced by the owners is not to find tenants, but to distribute the lots so as to arouse the least possible amount of jealousy and ill-feeling. The competition for these gardens is not, as might have been supposed, entirely among the poorer classes. On the contrary, the middle-class inhabitants are equally eager for the accommodation of a large kitchen garden; and there are few tradesmen in moderately-sized provincial towns who have not got allotments. This is, of course, exclusive of those who have private gardens of their own; but the number of these is comparatively few. If any one will take the trouble to visit the allotment gardens of a provincial town (some of these gardens extend to as much as 15 acres or more) he will find men there at work whom he would never have dreamt of seeing. They are at work, not from necessity, but out of that natural pleasure and delight which human nature feels in gardening. Here are gentlemen of good social position in middle-class life, tradesmen of considerable property, engaged in gathering Peas, sowing Carrots, or earthing Celery. The occupation is not looked upon in any way as degrading, or as a confession of poverty, but purely and simply as a healthy amusement, and a change from the confined atmosphere of the shop and counting-house. If this is the feeling among the fairly well-to-do, who are well supplied with all the comforts of life, how much stronger must it be in those who barely earn enough for the subsistence of themselves and families. The keen desire these poor people feel for an allotment is evident in the struggle they make to possess one. The very first question a man asks when he begins to work in a new place is, if he can get an allotment. If he can, he is satisfied. If not, he grows daily more discontented, as he marks the cost of the vegetables his family consume, and the scantiness of the supply upon the table. Beyond the mere economical part of the question, there undoubtedly exists, deep down in human nature, in the rudest as well as in the most refined, a delight in watching things grow; a pleasure in inserting the seed, and noting the first tiny green speck that appears. There is an undefined and almost holy joy in watching the development of life.

Effect of Allotments on the Labourer.

The use of an allotment appears to those who have resided among the agricultural poor to be productive of unmixed good. The labourer has then something which he can call his own; something which he can shape after his own heart. Brought up from his childhood amidst the operations of agriculture, he feels a natural desire to repeat the lessons he has learnt in natural economy on his own land and for his own benefit. Over and above the purely pecuniary side of the question, there rises up the even more important one of the labourer's own individuality. Too often that individuality is lost sight of, and he is considered as merely a cypher, an atom in a great concrete mass, as a soldier whose personal welfare is of little account so long as the army win the battle. But the real fact is—a fact which all thinkers must acknowledge—that the labourer is an individual, with a mind as well as a body, ideas as well as arms to work with. The very first step in the education of the man is to increase his individuality—to increase the sense of originality, so to say. In the operations of the farm he is merely a machine, for no work requires so little thought as ordinary agricultural labour. Give him an allotment garden and he becomes a human being whose powers are called into action. He has to calculate the proper amount of seed, to divide the area into proportionate patches of various vegetables, and to sow at the right season; to trim, and arrange, and all this by himself, and out of his own head, not in obedience to orders set before him. It is true that the amount of intelligence required is not great; but, without this aid, even that amount may lie dormant. The bodily comforts that arise from allotments cannot be disputed. Where children cannot get a full supply of rich and nutritious meat, and certainly our agricultural children do not get anything approaching to an adequate amount of animal food, the next best thing for them must be a bountiful share of vegetables. In point of fact, the quantity of vegetables consumed by a labourer's family is enormously large, especially of the three most favourite sorts, *i.e.*, Potatoes, Cabbage, and Onions. Cabbage is quite as extensive an article of food as the Potato, and the labourer makes few meals without an Onion. The Potato disease has been a terrible weight upon the poor, far heavier than the high price of coal or the rise of meat. The

Potato crop can now no longer be depended upon. It thus often happens that one-half of the allotment or garden fails to produce sufficient to pay the nominal rent, or to recompense the tenant for his labour. All possible expedients have been tried without success: the fatal fungus still makes its appearance—fatal indeed to the poor. This pest causes a tendency to cultivate Cabbages, which are therefore more largely grown than would otherwise be the case. Many say that the crop that pays them best is Onions. There is always a demand for them all the year round. Comparatively speaking, Carrots, Peas, and Beans, are of secondary importance. Turnips are great favourites, but require too large an area. How many a drunkard's family, whose head spent all his earnings in liquor, would have been starved had it not been for the produce of the allotment garden? When a man finally takes to selling the produce of his garden for drink, you may be sure that he has reached the lowest step of the ladder. The practice is unfortunately too common, and it is difficult to see how to prevent it. The price paid by the agricultural labourer for his allotment is usually very low. In some cases, where the land is poor, and the owner is the lord of the manor, it has been let at as little as 3d. per perch. The glebe-allotment alluded to previously, was let at 5d. per perch. The general run varies from 6d. to 1s. 6d. in crowded villages and small towns. In towns the rate rises with the ratio of the population, but is never so high as to impede the profits of cultivation. It is not necessary to enter upon an enumeration of the benefits which allotments confer upon the inhabitants of towns. The circumstances from which some little opposition has arisen to the allotment system, have been mainly the unfortunate relations which have lately existed between master and man; but it is to be hoped that no such disturbances will have the effect of depriving the labourer of this great necessary of his life.

Large Allotments Undesirable.

Another, and much more forcible objection, is that stated with some dogmatic energy, that the use of a large allotment ground tends to make a labourer an idle man. The argument appears paradoxical, but it has much more sense in it than may be imagined. A labourer becomes the tenant of a large piece of ground—say a quarter of an acre. He cultivates it, and really finds a profit from it. Over and above the vegetables eaten by his family, he is enabled to sell some surplus stock, and to pocket the profit in hard cash. He keeps a pig and fattens it upon the refuse. The sale of this pig places him in possession of several pounds, to him a large sum of money. So far so good. But now comes the mistake. If he is a man of some enterprise, and imbued with a desire to rise, or, what has much the same effect, is excited by avarice, he begins to make a very ancient and erroneous calculation. If a quarter of an acre will produce all these advantages, half an acre will produce twice as much; and an acre or two will even entirely support him. Filled with the idea, he takes an additional plot of ground, raising the extent of his holding perhaps to as much as 3 acres, and then his difficulties commence. In order to attend to this area properly, he is obliged to devote whole days to it, and sometimes a succession of days. The wages of these days are at once lost, and are to be reckoned as so much on the wrong side of the account. This intermittent attendance at work brings him into ill-odour with his employer; and finally ends with his renouncing regular work, and taking to do odd jobs, which bring in a precarious livelihood, and leave him without wages in the winter, when he wants them the most. Still, even now that he is master of his own time, he cannot properly attend to his miniature farm by himself. The weather steps in and impedes him. It may happen that a few days only are favourable to seeding, or to getting up; and, if these are lost, the season may be lost. His single arms and hands cannot do the work sufficiently fast. Then he has to call in aid, and to pay for that aid; and this goes to the Dr. account. Now he finds that while one pig was profitable, inasmuch as it costs nothing to keep, two or three require more food than the broken scraps his family leave. He must buy food for them if he wishes them to fatten. Here again the figure goes to the wrong side of the book. The pig, in fact, is the one thing about which a labourer might be naturally supposed to know most, and yet is the very thing upon which he commonly entertains the most exaggerated ideas. The real fact is, that the profit he derives from a pig is not made out of the pig itself, but because the pig acts as a savings' bank. He has to invest a few shillings to purchase it; that represents the original deposit. Then the scraps which would otherwise be wasted are consumed. Small sums that he would have wasted in drink are expended in the purchase of food for the pig; and presently when it is sold, lo! these unrecognised savings are returned, and the man is firmly convinced that he has been engaged in a most profitable transaction. If the money had been deposited in a savings' bank it would come to pretty much the same thing. Of course there really is a margin of profit, but very much

less than the enthusiastic labourer reckons; and he discovers this to his cost when he comes to keep two or three. In a very short time he finds that it is impossible to obtain a living from this small holding, and his thoughts are then turned towards the means by which he may augment his income. Perhaps he is a member of some religious body, and finds a friend who lends him a small sum of money, with which he purchases a cow. But here again he finds that the animal has a mouth. The produce of the garden is totally insufficient to support the cow any more than a number of pigs. He endeavours to supplement it by feeding the cow on the Grass at the roadside, but this is soon stopped by the police. Shortly the cow grows miserably poor; this decreases her milk. The calf is a wretched thing; it may die before it becomes saleable. He cannot afford to keep it long enough to get a really good price—sufficient to cover the previous loss of income through cessation of milk. It comes to much the same thing if he buys a horse instead of a cow, and tries hauling. The horse, never a good one, is brought down by lack of proper food to a skeleton, and becomes useless. It frequently happens that a farmer, struck by the persistent efforts of the man, will take pity upon him, and allow him to pasture the horse for nothing: and I have known instances where farmers have bought such men fresh horses when the old died from exhaustion and starvation. Yet somehow they never seem to prosper. The end is always the same—the land has to be given up, and the man returns to farm labour. There are to be found men in every village who get a living, and a fair living, by hauling, and these often have two or three small fields; but they do not pretend to make their income from gardening. It is the haulage which supports them, and there is only room for a very few haulers; so that it has become a common saying, that if you want to ruin a labourer give him a large garden. This arises from the over-estimate he draws of its capabilities. These facts do not militate against the general utility of allotments, but they do very strongly oppose the theory that land should be divided into small farms of 4 acres each, and that such a division would be favourable to the prosperity of the country. Imagine the picture that has been drawn, and which any person who likes can verify for himself; imagine this state of things prevailing over a wide extent of country. It has been calculated that a man can just support life upon the produce of 4 acres; but, as we have seen, what a life! liable at any moment to be disabled by an inclement season, for ever struggling with Nature for a hand to mouth existence. Surely no wealth, no flow of prosperity, could accrue to a nation thus employed. The reason of the wide-spread belief in the advantages to be derived from such a national system of allotment gardens, is the single assertion that the produce of a garden, well cultivated, is far greater than that of a field under the plough. It is pointed out that a labourer can pay so much per perch for an allotment, and yet make a good return; while the aggregate of the sums thus paid as rent are greater than the farmer gives, *i.e.*, an acre let out as allotment gardens returns more to the landlord than an acre rented by a farmer. This is certainly true, even in villages where land is not valuable, and very much more so in the neighbourhood of towns; but, upon examination, both these assertions, though based upon fact, cannot be used as arguments in favour of a national resort to the system, for the following very potent and very obvious reasons. The produce of a certain area cultivated as a garden is, indeed, greater than a similar area upon a farm; but the difference solely arises from the variety of the crops. Thus, it often happens that a labourer who has an allotment, after growing vegetables for a time, will sow Wheat as a change. Now, compare this Wheat with that grown in the adjacent corn field, and it will be found to be no better. In fact, Wheat is often produced by good farmers who use steam, or plough deep and do not spare manure, such as no allotment or garden ever brought forth yet. Then there must be taken into account the profits obtained and the benefit derived from the sheep and stock kept by a farmer. Every acre goes to assist in maintaining these. But it is impossible to maintain stock in allotment gardens; therefore the balance as to the produce of food for the people, both as regards Wheat and meat, is in favour of farms (especially large farms) and against allotments. It is well known that in Belgium a very large section of the population in one part obtain their living by the cultivation of plots of land very similar to our allotments, only considerably larger; but they cultivate many other plants besides those which are found in our gardens, as Colza, which they grow largely, and even Tobacco. A commercial element is here introduced into the question which is not present in England, and which is altogether separate from the problem of the production of food. The results, therefore, to which these considerations bring us appear to be:—Firstly, that the allotment system cannot be too widely extended, as a means of affording additional and varied food,

as a relaxation to the overworked, and as an influence acting in favour of general moral good. Secondly, that it cannot at present take the place of high steam cultivation, which is far more effectual an agent for the production of Wheat and meat. Thirdly, that any scheme by which the land would be divided into small plots or allotments must fail of its object, and would reduce the projectors to the condition of savages, or little better. Fourthly, that a plant requiring careful and minute attention, and bearing a high value in the commercial world, must be introduced before allotment gardens can become successful pecuniary speculations in a national sense. As regards the allotments themselves, some purely practical code of regulation is desirable.

Allotment Companies.

Numerous companies have been formed for the purpose of supplying the workmen with houses; the building societies and their estates are situated outside the city, but within easy reach by rail. Why should not societies exist and flourish, for the equally useful object of providing the workman with a garden? If the plan of universal division of land were thoroughly carried out, it follows that the cities would disappear, since, to obviate a bare living out of the 4 acres, a man must live on or very near to it, and spend his whole time in attending to it. But the extent of allotment-ground which such a society as this would provide for the workman must not be so large as to require any more attention than he could pay to it in the evening, or the Saturday afternoon, or, at most, in a day or so of absence from his work. He would have, of course, to go to his allotment by rail, and rail costs money. But how many thousands of workmen at this very hour go to their work day by day by rail, and return home at night? and the sum of money they thus expend must collectively be something enormous in the course of a year. To work his allotment he would have no necessity to visit it every day, or hardly every week. Such an allotment-ground must be under the direction of a proper staff of officers, for the distribution of lots, the collection of rent, the prevention of theft, and generally to maintain the necessary order. Looked at in this light, the extension of the allotment system to large towns does not hold out any very great difficulties. The political advantage which would accrue would be considerable, as a large section of the population would feel that one at least of their not altogether frivolous complaints was removed. As a pecuniary speculation, it is possible that such a society would pay as well as a building society, for the preliminary expenses would be so small in comparison. A building society has to erect blocks of houses before it can obtain any return; but merely to plough, and lay out a few fields in regular plots, and number them on a plan, is a light task. If the rent was not paid, the society could always seize the crops; and, if a plot was not cultivated in a given time, they might have a rule by which the title to it should be vacated. To carry the idea further, a small additional payment per annum might make the plot the tenant's own property. This would probably act as a very powerful inducement.—Abridged from the "New Quarterly Review."

TOUGHENED GLASS.

ALTHOUGH the manufacture of glass has been carried on for about 2,000 years, it does not appear that any attempts to overcome its inherent brittleness and liability to fracture, and at the same time to preserve its transparency, have proved successful—if, indeed, they have ever been made, which is doubtful. It is true that the French philosopher Réaumur many years since hardened glass somewhat by exposing it to a high temperature for a considerable time. But this process which is technically termed devitrification, while it hardens, at the same time crystallizes the glass and renders it opaque, the product being known as Réaumur's porcelain. Seven years since, however, M. François de la Bastie, a French engineer, discovered a simple means of rendering glass practically unbreakable, and at the same time of preserving its transparency. There were many delicate conditions involved in the process by which he obtained this result; and on endeavouring to repeat the successful experiment he failed signally. For two years more he strove without avail to re-discover the secret of his success. At length, however, he succeeded in so doing, and has since been engaged in perfecting his invention and in developing a laboratory experiment into practical working. The process of conversion in the main is a very simple one, so simple that it seems singular it was never thought of before. Broadly stated, it consists in heating the glass to a certain temperature and plunging it while hot into a bath consisting of a heated oleaginous compound. To the efficiency of this process, says the "Times," we can testify from the inspection of a number of toughened glass articles at the offices of Messrs. Rey, 29, Mincing Lane, the representatives of M. de la Bastie in England. In these articles, which consisted of watch-glasses, plates, dishes, and sheet glass, both

coloured and plain, neither transparency nor colour is affected at all, and the ring or sound only slightly. These articles, some of them being exceedingly thin—were thrown indiscriminately across a room against a wall and fell spinning on the deal floor. Water was boiled in a saucer over a fire, and the saucer was quickly removed to a comparatively cold place, and was unaffected by the sudden change of temperature. One corner of a piece of glass was held by the hand in a gas flame until the corner became exceedingly hot, but the heat was not communicated to the other portion of the glass, neither was it cracked from unequal expansion. A comparative experiment was then made with a piece of ordinary plate glass, and a similar piece of toughened glass, in order to show their respective powers of resistance to fracture, from the force of impact by a falling weight. In each case the glass was about 6 inches square, and was placed in a frame, the weight being dropped upon its centre. With the ordinary glass, a 2-oz. brass weight falling on it from a height of 12 and 18 inches respectively did no damage, but at 24 inches the glass was broken into several fragments. With a thinner piece of toughened glass no impression was made by the same weight, falling from heights ranging from 2 to 10 feet, the weight simply rebounding from off the glass. An 8-oz. iron weight, tried at 2 and 4 feet respectively, gave similar results. Upon the height being increased to 6 feet, however, the glass broke. But here another singular result was produced; instead of breaking into about a dozen pieces, as did the ordinary glass, it was literally smashed to atoms. The largest fragments measured about half an inch in length and breadth, and these were easily reduced by the fingers to atoms varying in size from that of a pin's point to that of a large pin's head. The lines of fractures in the fragments presented to the eye the appearance of irregular lace-work, and these lines were, moreover, apparent to the touch, but more palpably so on one side of the glass than on the other. Which of the two sides was the one that received the first impact of the blow we were unable to determine. Another peculiarity is that the edges of the fractures are by no means so sharp, and therefore capable of causing incised wounds, as are those of ordinary glass. It would seem that the toughened glass possesses enormous cohesive power, but that if the equilibrium of the mass is disturbed at any one point the disturbance or disintegration instantly extends throughout the whole piece, the atoms no longer possessing the power of cohesion. Of the practical character of M. de la Bastie's discovery there can be no question whatever, nor can there be any doubt of its value. The applications which suggest themselves are innumerable, but for the present there remains one purpose to which toughened glass cannot be so easily applied, and that is to window glazing in odd sizes, inasmuch as it cannot be cut by a diamond or other ordinary means. Our glaziers will therefore have a respite, but we cannot give them much hope that it will prove a long one, as experiments of considerable promise are being conducted with the view of solving this problem. Moreover, the glass can be cut to the proper sizes before toughening if desirable.

WHAT WILL THE GLAZIERS SAY?

"LET all in vitreous tenements who dwell"
(Tupper, an old saw set in a new strain)
"Forbear the flinty missile to propel."
Proverbial wisdom-teachers must explain
Hereafter, when Brown, Robinson, and Jones,
May in glass houses live, and yet throw stones.
Paterfamilias, look what hope appears!
Thou, as of old, will be distressed no more
With jingle, too familiar to thine ears,
Of glass or tumbler dashed on kitchen floor;
And windows smashed by boys who roam,
Or thine own idle brats at home.
Thy casements shard and pebble will defy,
Nay, taws from "catapults" let fly.
Thy tumblers will stand falls, decanters flinging.
If guests should ever bottles shy.
Yet toughness hinders not hard glass from ringing,
With unimpaired sonority of tone:
Glass bells in steeples soon will chime,
Big Bells, perhaps, in no long time
Instead of being founded will be blown.
What may posterity not make?
Cannon perhaps, fortifications,
Out of a glass no common force can break;
Our "Alexandras" and our "Devastations"
And "Minotaurs," "my lords," in future days,
Instead of plating, possibly will glaze. —"Punch."

THIS is the season when the editor shouts up the pipe to the printer, "The poem sent up yesterday, headed, 'Spring is Come,' you can keep over for another week."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Kitchen Garden.—Where Chicory is held in estimation as a salad plant a little of the seed should now be sown in rows, 12 or 14 inches apart; drop a few seeds at intervals a foot asunder in the rows, and, when up, thin the plants out to one in each place. By thus giving them room enough the roots acquire double the strength which they attain when grown thickly; one good plant produced in that way will furnish as many leaves fit for use as three small ones. All the attention required afterwards through the summer is to keep the hoe going sufficiently to destroy weeds as they make their appearance. Of Chervil a little should now be sown thinly on well-prepared soil, and covered lightly. Rampion, Salsafy, and Scorzonera, may all be sown towards the end of the month, in rows, 14 inches apart, putting the seeds in thinly, and still further thinning the plants if too close when up. Through the summer keep the surface well stirred with the hoe. For mere appearance sake, to make the ground smooth, the rake is often used immediately after the hoe; but, amongst culinary vegetables, this need never be done, unless it is necessary to remove weeds that have got much larger than they ought to have been allowed to grow before the hoe was used. Ground raked smoothly when wet becomes hard and baked, and, when dry weather sets in, loses moisture by evaporation much faster than that which is loose and open for an inch or two deep, a condition that also best befits it for absorbing the falling rains. By frequent surface stirrings, too, the crops get the full benefit of any manure that may have been applied, instead of helping to support, as it often does, a vigorous weed growth.

Pits and Frames.—A good substantial hotbed should now be prepared to receive the Melons sown a short time back; this should be made of well prepared dung and leaves, and, when finished, should be 4 feet 6 inches high, and should extend beyond the frame half a yard on all sides. Slight beds for either Melons or Cucumbers are useless until further on in the season, when the weather is warmer; for, whilst the nights are yet cold, they require so much labour in replenishing the linings with fresh manure. As Cucumber plants get strong they will require more water both at the root and overhead. Syringing should be attended to early in the afternoons, whilst the sun is yet warm, always using tepid water, both for this and for watering; 90° is a safe temperature at which to use it, and, if the heat of the bed is at all declining, water at this temperature will in some measure assist it. When the shoots of Dahlias get from 3 to 4 inches long they should be taken off at the lowest joint, and put singly in small pots, in half loam and sand, plunging them in a bottom-heat of 80°, and keeping the soil moderately moist but not too wet. Tomatoes, as soon as large enough to handle, should be shifted from the seed-pans into 48-sized pots, placing two plants in each; keep them in a growing temperature and near the glass. If autumn-struck bedding Pelargoniums are yet thickly together in the pots in which they have been wintered, they should at once be potted singly in small pots, giving them half loam and half leaf-soil, with a little sand; place them for a fortnight where they will receive a little warmth, in order to induce them to grow, after which they should be gradually hardened off in cold frames. Verbenas, Heliotropes, Lobelias, Ageratums, and all similar bedding plants, should, as they become rooted, be placed in small pots, singly, or in boxes 3 inches apart each way. Boxes are best, as the plants grow until bedding-out time much better than in pots, and there is also in this method of treating them, a great saving in the labour of watering; nip the points out to make them bushy, and make careful examination for aphides, Verbenas being especially subject to them; fumigate, or syringe with tobacco-water, on the first appearance of these pests, or they will quickly spoil the plants. See that Calceolarias are not too much crowded, and that they are well supplied with water; if they suffer for want of moisture at the roots, they get into a hard stunted condition, and will never afterwards grow freely, but will more frequently go off the first dry weather that occurs after they are planted out. Alternantheras, Iresines, and Coleus should be kept in a growing temperature, as there will still be plenty of time to harden them before the time comes for planting them out; if put out too soon, they get chilled, and do little good. Sedums, Sempervivums, Echeverias, and Centaureas should be kept where they will receive plenty of light and air every day, so as to induce a stout robust growth. Such sub-tropical plants as Cannas, Solanums, Wigandias, Chamæpence, and Humea elegans, should be well attended to; these are free-growing subjects, and, if allowed to become pot-pound, some time must elapse before they move freely after being planted out. Golden Pyrethrum, variegated Arabis, Golden Thyme, and similar plants, may, with advantage, be at once planted out in the places they are to occupy, if the beds are at liberty; this will be so much done when the time for a general planting out arrives, and the plants will thus be getting gradually esta-

blished, and be rendered sooner effective. Where sub-tropical plants are grown, two of the best and most distinct for standing side by side, and forming an effective contrast, are *Acacia lophantha* and *Ficus elastica*. These should be largely employed, for, even if the season should happen to be unfavourable for this class of plants, these two never have the forlorn appearance that some subjects have. Nor should the old *Ricinus communis* (Castor-oil plant) be lost sight of; it looks well in any situation where it is not too much exposed to the action of wind.

Houses.—Camellias will now be making their growth, and must be well supplied with water at the roots, and also syringed overhead freely. Many amateurs do not succeed well with these plants, which get into a yellow unhealthy condition, in which state they make little growth and few flowers, and, where such is the case, although they will bear a deal of bad treatment without dying outright, it is a somewhat difficult matter to bring them round. One of the principal causes of this state of things is often attributable to their receiving an insufficiency of water, especially whilst making their growth. At no season, however, will the Camellia bear getting too dry, the large amount of leaf surface which the plant possesses causing the moisture to evaporate with great rapidity. Moisture must be supplied through the roots, which, if in too dry a condition, fail to perform the work required of them. Camellias are, in this country, most generally grown in loam, but for amateurs who are not thoroughly skilled in their cultivation, I should recommend peat as the better material to use. This being more retentive of moisture, is more likely to prevent the ill effects of drought. It is not advisable to pot Camellias at the present season, unless they are suffering seriously for want of root-room. Moving them now is sure to interfere, more or less with their flowering; if it be absolutely necessary, avoid as much as possible interference with the roots. In potting, whether the soil used be loam or peat, add as much sand as will keep it from getting sour, especially as it is necessary to ram the new soil so as to make it as close as the existing ball of the plant, otherwise the water afterwards given will escape through the new soil. Whilst making growth, shade is indispensable. Attend carefully to plants that are intended for summer flowering. Large Fuchsias should be supplied with a stout central stake to support them, and the shoots should be stopped, so far as is required, to furnish the plants, and give them, when in flower, a dense well-furnished appearance. If in small pots, the application of weak liquid manure once a week, will assist them, but for these plants it must not be overstrong or it may have the effect of causing both the advancing flowers and leaves to fall off. Young Fuchsias that have been struck during the autumn and winter should be moved into their flowering pots. These plants will succeed the larger ones in blooming. Petunias should be kept stopped so as to make them bushy. These, especially the double kinds, are useful for summer flowering, as they continue to bloom for a length of time after flowers are scarce. Azaleas now in flower will require shading from the sun, and this is also the case with Cinerarias, Amaryllis, Acacias, *Cytisus racemosus*, *Hortensias*, *Deutzias*, and other similar plants. Roses in pots that have been for some time in a greenhouse temperature will now be pushing their flower-buds. Do not place them near the front lights, as a cold current of air upon the young tender leaves is favourable to the development of mildew. Assist them with manure-water every alternate time they require watering, and, if aphides make their appearance, fumigate at once. Amongst a general collection of plants at this season, this is a matter that requires constant attention. Slight and frequent fumigations are much the best; but if two or three gallons of tobacco-water be kept at hand in a vessel, so that any small plants that are affected can be dipped, and larger ones syringed, a considerable saving of both labour and material in fumigation will be effected, and the disagreeable smell of the tobacco be avoided. Where means exist for forcing flowers in winter, provision should at once be made to have the necessary plants coming on for the purpose. *Epacris*, *Acacia Drummondii*, *Cyclamens*, *Genistas*, *Abutilons*, *Bouvardias*, *Epiphyllums*, *Correas*, *Myrtles*, *Monochaetums*, and the Sweet-scented *Daphne indica*, if encouraged to make their growth early in the summer, and their wood is well ripened in the autumn, can, with a little heat, be brought into flower through the winter and early spring months.

Rewards for Wasp Catching.—If horticulturists and others interested in gardening would combine and offer small rewards for the capture of wasps at this season, it would have the effect of reducing their numbers—a most desirable result; for, in spite of all that Sir John Lubbock may advance to the contrary, wasps are perhaps the most mischievous and malicious pests with which gardeners have to contend. For years past my practice has been to give a penny each for wasps from Christmas to the 1st of June; our village children are, therefore, keenly alive to the importance of catching them. I may add that I killed the first wasp which I have seen this year on the 24th ult.—WINCHMORE.

THE KITCHEN GARDEN.

SEAKALE GATHERED ON THE HAMPSHIRE COAST.

BETWEEN Calshot Castle and Leap wild Seakale grows luxuriantly on the beach, just above high-water mark, and those who live close to the shore claim so much of it as is opposite their domain. In autumn, when the stems die down, they cover each stool with shingle, to the depth of 18 inches or 2 feet, an operation which answers two purposes—it keeps the crown from being trodden under foot in winter, and when the Kale commences to grow in spring it blanches it. It is generally fit to cut about the middle of March, but this season, like other vegetables in this locality, it is a month later than usual. A good harvest is made of it when fit to cut, which is just before it peeps through the shingle. The latter is carefully removed by the hand, so as not to break the tender stalks, which turn out quite clean and well blanched. When cut it is sent to Southampton and Cowes, where it finds a ready market at 6d. per lb. Although all the crowns are covered at the same time they do not all come in at one time; we commenced cutting on the 1st of this month, and to-day (April 12th) I have examined some of the heaps and find the crowns only just commencing to grow; cutting generally lasts three weeks. I see no reason why Seakale should not be grown on the coast everywhere, that is, where any space is left above high-water for its accommodation, for it would doubtless grow on other parts of our shore as well as here and at Whitby, where I have seen it cultivated. I would advise all who live in the neighbourhood of our seaport towns where any beach exists above high-water mark, to sow some seed in the following manner.—With a shovel open a trench a foot deep, if shingly; but, if sandy, half that depth will do; sow the seed in it as you would Peas; then fill it up, which is all that is necessary until the roots are large enough to be transplanted, which, if the seed be sown in March, will be in the succeeding March. Take the roots up as carefully as possible, and plant them in fours in squares 9 inches apart and 3 feet asunder between the squares, which, if in lines, should be 6 feet distant from one another. When covering the crowns for blanching the shingle may be heaped up over them in ridges along the lines.

W. W. EAGLEHURST.

[Along with this came samples of the Kale in question which was well blanched, stout in growth, and in every way, excellent; and, when cooked, the flavour was even more delicate than that of ordinary forced Seakale. Our correspondent informs us that its growth is not so strong this season as it is in general; last year it produced stems about 9 inches long, each of which weighed a pound, and some 20 ounces.]

CORKLESS BOTTLES GOOD BIRD-SCARERS.

SOME years ago, I found the small birds unusually daring in defying the feathers and kite-tails placed as a guard over the Broccoli seed beds. The crop had been pretty well cleared by them on three successive mornings, when I happened to meet an old man, who I knew was an experienced gardener, and to him I stated my case, and asked him if he knew of any easily-applied remedy. "Did you ever try bottles, sir? But you must not put corks in them." "No, I will not put corks in them," I replied; "and now tell me all about it." He then directed me to place a dozen clean empty wine bottles at equal distances over the beds. I did so, and the very next morning there appeared above the ground what remained of the seed, in sufficient quantities to supply my garden, so that I did not find it necessary to raise any more plants. This remedy is not always successful. I found it did not keep the birds off the later Pea crops, and I attribute its partial failure at other times to the bottles being left on the ground after the plants are safe, and the birds have recovered from the fright occasioned them by the bottles, so that when the latter, after standing on the ground a month, are merely shifted to a new situation a little further off, they have not the same effect as they had in their former position. Again, when much pressed by hunger, or greatly tempted by the sight of what they like, birds will face any sort of scaring material, and nothing but netting or some such protection will keep them off. Bits of tin, glass, and coloured streamers, availed nothing to deter that worst of all garden pests, the bullfinch, from clearing off in a few hours nearly all the bloom buds of a fine young pyramid of the Apple called Cox's Pomona the year before last; and last year I only saved a portion of the crop by covering

the whole tree with a net. While on this subject I may mention that for Peas I have found the following an easy and a successful protection, applied just before they appear above the ground. Two pieces of slater's lath about a foot long, with a hole at each end made with a half-inch centre-bit, and with about a dozen copper nails driven into one side and standing up about half-an-inch, are secured by means of pegs driven into the ground through the holes, one at each end of the row; then a ball of fine twine is wound off along the rows and across the nails backwards and forwards till the ground is pretty well protected by the twine. In a fortnight or so the twine can be unwound and the laths removed to a succeeding crop. A few sticks should be laid across the rows at intervals to keep the twine an inch or thereabouts above the ground.

B. S.

The Golden Trophy Tomato.—This new and beautiful yellow Tomato originated in 1871, with Mr. A. M. Halstead, an experienced American horticulturist. It is a sport from the well-known Trophy, but is a stronger and more rapid grower, is much more productive, and ripens a week earlier, continuing until frost. The fruit is almost an exact counterpart of the Trophy in form and size, of a beautiful light yellow or straw colour, occasionally faintly streaked with red; the flesh is very firm and solid, containing but few seeds. Its flavour is entirely different from any variety with which we are acquainted, being free from the strong Tomato taste and fragrance which belongs to most other varieties; has very little acidity, and when eaten raw without seasoning, resembles in flavour some varieties of Apples. This, which is described in Mr. Bliss's catalogue, appears to resemble in flavour the yellow Tomato shown by Messrs. Carter last season.

New Potatoes in the Open Ground in January.—I have been informed that Mr. Gilbert, of Burghley, and others living in that locality, are in the habit of taking up large quantities of new Potatoes from the open ground in January. If I understand aright, the method pursued is as follows. Plant in July, and upon the approach of frosty weather cut off all haulm, and cover up the rows with dry leaves or litter. Now, if this be so, perhaps Mr. Gilbert, or some of his neighbours, who have practically tested the scheme, will not object to give, in the columns of THE GARDEN, their experience in this, to me, very important matter. I have tried the experiment myself on a small scale, but with most disastrous results. I found that as soon as our autumn rains set in, the disease attacked the young and tender haulm in so virulent a manner, that when I dug for my anxiously looked for new Potatoes at Christmas, not a single sound tuber could be found. Possibly Mr. Gilbert's success, if successful he has been, is owing to some peculiarity of soil or climate.—B. CALVERT, *Terlings, Harlow.*

Trial of Dwarf Forcing French Beans.—Of selected Syon House Dwarf Bean, sown on the 1st of January last, I gathered the first pods on February 18, the length of the pods being $4\frac{3}{4}$ inches, whilst Sir Joseph Paxton Dwarf Bean, sown on the same day as the Syon House, did not produce pods fit for use till February 22; but its pods measured $5\frac{1}{4}$ inches, and were of a beautiful shade of green. From Osborn's Forcing Dwarf Bean, sown on the same day as the above, I gathered the first pods on February 22, as in the case of Sir Joseph Paxton; the length of its pods was 3 inches. Canadian Wonder, sown on the 1st of January, was a failure; with me it is a late Bean, a strong grower, and not adapted for pot culture. The variety which I grow under this name is of the red Flageolet type, and one of the best for out-of-door culture. Selected Syon House—which, as will be seen, was four days earlier than either Sir Joseph Paxton or Osborn's Forcing—is a good cropper; but its pods are not so long as those of the two just named. Of Sir Joseph Paxton and Osborn's Forcing, I give the preference to Sir Joseph, both as regards length and colour of pods. Both are good croppers.—DAVID LUMSDEN, *Bloxholm Hall Garden, Sleaford.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Red-skinned Flour-ball Potato.—Much has been written in favour of this Potato. I have grown it for several years, both in fields and in the garden, and in various soils; but I have in all cases found it when cooked to be of very inferior quality, and certainly not less subject to disease than Victoria and other superior sorts. I have, therefore, now finally discarded it.—J. BELL, *Strathfieldsaye.*

Rollisson's Telegraph Cucumber.—Mr. Gilbert I see considers this the best winter Cucumber; in my opinion it is also the best summer variety. I planted it on the 6th March, last year, in a span-roofed house, 19 feet 6 inches by 10 feet, which is not sufficiently heated for planting earlier. I began to cut on the 30th April, and during the season 827 fruits were registered as taken off the plants by my foreman, several more being cut by myself which I omitted to put down. The fruits were fine and handsome, many of them fit for exhibition, the sort being quite true to name, as I had it from Messrs. Rollisson some years since. Will not this bear comparison with any of the new varieties?—JOHN GARLAND, *Killerton, Exeter.*

ORCHIDS AT STEVENS'S.

THE holders of collections of Orchids used to look aghast in time past at the increasing importations of them from both the Old and the New World; they, in fact, anticipated a downfall of value in the then existing stocks such as has never been realised; for, as fast as one cultivator fell out of the ranks, as the sequel has shown, two were always ready to take his place. The taste for Orchids, however, was never so pronounced, at least, so far as my knowledge carries me, as at Stevens's the other day (April 8th). On that occasion a tempting catalogue was issued, announcing, among other things, the sale of *Dendrobium Wardianum* and *D. Falconeri* in such masses as people never dreamt of, and the consequence was a crowd of buyers from most parts of the United Kingdom, and accordingly a brisk sale. An outsider who does not understand much about plants would have scarcely gathered the lot together, so desiccated and dying-like would they have appeared to his untutored eye, and yet that heterogeneous mass realised no less than between £1,400 and £1,500, by far the largest sum, perhaps, ever realised for imported Orchids in one day. How that money mounted up will surprise nobody when it is stated that one plant alone realised the handsome sum of 100 guineas. Growers and others well acquainted with Orchids were speculating what that plant would bring; some thought it would scarcely fetch twenty guineas; few, if any, supposed it would double that sum, but the bidding, which began at twenty guineas, went up first in fives, then in tens, then in fives, until it was knocked down—after a spirited competition between Mr. Wrigley, of Manchester, and Lord Londesborough—to the latter at the sum just named, viz., 100 guineas. We have scarcely a word to say about the value, for a plant or anything else is said to be worth just what it will bring, and no more; only this, we may be safe in saying that no nurseryman could have obtained that sum for it privately. Many of the lots of the same kind were disposed of, all at fair prices, and numerous others are catalogued for this week, which, in all likelihood, will bring good prices. The species in question comes from a new locality, and is undoubtedly distinct from, although closely allied to, *D. Wardianum*. The chief feature of the latter is that it emits its long whip-like pseudo-bulbs in an undulating fashion, differing both from the species sold in that respect, and from *D. Boxallii*, another excellent *Dendrobe*. Moreover, it appears to me that there is also either a vast dissimilarity among the pseudo-bulbs, as taken from their native habitat, or two distinct species are co-mingled one with another. The striking plumpness of the one, almost concealing the nodation, which catches the practical eye in discerning between one thing and another, is conspicuous in comparison with the purely cylindrical form of the other, which, albeit, is more conspicuous for "swelling at the joints." The flower, too, which Mr. Low showed me, is possibly more decided in the yellow of its labellum, which, of course, is no botanical distinction, but is nevertheless one which has weight with gardeners; besides the form of the labellum is not so convolute, nor is the flower so large; but, then, the number of flowers on the pseudo-bulbs, and their free formation, point out at once that we have either a vastly-improved habited *Wardianum*, or a distinct species. However, be it similar or dissimilar to any existing species, it is doubtless a very excellent *Dendrobe*, and it is to be hoped that more of it will be forthcoming some day. The plants of *D. Falconeri*, from the same habitat, were excellent; indeed, they reminded me of the vegetation of some bygone epoch; and it is to be hoped that our Orchid growers will be able to maintain the stamina and development of flowers which such luxuriance ought to ensure. After all, cool Orchids do not maintain an isolated supremacy. There is room yet for good things, and plenty of them too, no matter from what quarter of the globe they come.

JAMES ANDERSON.

Meadowbank Nurseries, Uddingston, N.B.

Cutting Timber during a Shooting Lease.—An appeal case was brought before the Lords Justices at the Court of Chancery, the other day, which raised a rather interesting question as to whether a person who has hired the right of shooting over an estate has the power of preventing his landlord from cutting down trees on the estate. It appears that in October last, the Rev. Henry de Foe Baker, the defendant in the present suit, agreed to let to Mr. John Gearn, the plaintiff, for a lease of twenty-one years, the mansion of Syrencot, Wiltshire, "together with the exclusive right of shooting, coursing, and fishing, over 1,300 acres, situated in the parish of Figheldean, Wiltshire, at the yearly rent of £125." On the 29th January last, the defendant caused to be put up for sale a quantity of timber on the estate, and the plaintiff alleged that the cutting down and the pulling up of this timber would involve the utter destruction of five of the plantations on the estate as covert for game. It was urged by the plaintiff that this would be in direct contravention of the spirit

and effect of the agreement. The bill sought an injunction to restrain the defendant from cutting down any trees in the coppices, woods, plantations, and belts on the estate. This injunction Vice-Chancellor Hall granted on the 18th ult., reserving liberty to the defendant to apply in chambers as to the cutting of any trees which had been sold but not yet felled. The defendant now appealed. Lord Justice James was of opinion that, with all respect to the Vice-Chancellor, the injunction which had been improvidently granted must be dissolved. Lord Justice Mellish was of the same opinion, remarking that "the right of shooting was a right to shoot over the estate in its proper condition of management, and the landlord did not, by such an agreement, deprive himself of the power of managing his estate in the way he might think best."

Explosions of Gas under Boilers.—"N. H. P.'s" complaint (see p. 292) reminded me of similar cases which have come under my own observation, one of which was in a dome or round-topped independent cylinder boiler, in which the outlet for the smoke was at the side, about 9 inches below the top of the boiler, thus leaving a cavity where the gas thrown off by the banked-up fire collected, till a tongue of flame broke through and fired it, causing a violent explosion. Were the building of the saddle boiler referred to by "N. H. P." examined, I have little doubt but that the flues will be found to go off low down at the back of the furnace, and that the upper part of the arch of the saddle, being built across at the back, will form a receptacle for gases, so that, when the fire is banked up for the night, and the furnace and ash-pit doors are shut, leaving no draught to carry away the gas generated by the smothered fire, it necessarily gathers under the arch of the boiler, until the flame comes through and it explodes. The only way to prevent this is to allow sufficient draught to carry it into the chimney, or to have the flues so constructed that the gas will find an egress at the highest point, and so pass up the chimney as fast as it is generated. No fire will burn without a sufficient supply of air to carry off the products of combustion, and many stokers err in the excessive use of dampers, &c., to stop all draughts, and so often put out their fires altogether.—AQUA-CALIDA.

The Tea Plant in Sicily.—An interesting experiment is about to be made in Sicily. A great similarity has been observed to exist between the soil and climate of Sicily and Japan, and this has encouraged the Italian Government to make trial of growing the Tea plant in the former island. Seeds and full directions for culture have been obtained through the Japanese consul, and the result of the experiment is awaited with some anxiety; Spain and Greece being similarly situated as regards latitude and climatic conditions, and so equally interested in the success of the scheme.—"Academy."

AN IMPROVED SCRAPER.

A SCRAPER, which it will be admitted is a great improvement upon the old-fashioned kinds, has been sent to us for trial, and proves in every way satisfactory. As will be seen from the accompanying

engraving, it is intended to scrape the sides as well as the bottom of the boot, two side-pieces starting out for that purpose upon the pressure of the sole of the foot, and, by means of balance weights, returning to their places as soon as the pressure is removed. This scraper, which is called the improved unique patent boot-scraper, is the invention of Mr. G. Pewett, of Highbury Place, Bath.

The Gum Tree not Hardy.—"L'Italie," a paper published in Rome, says that of 3,000 trees of the *Eucalyptus globulus*, planted at San Sisto Vecchia by the municipal government, none are in a flourishing condition; and of all those planted along the line of the railroad between Rome and Naples, only those near Naples are living. It is almost certain, says "L'Italie," that *Eucalyptus globulus* will not grow in a temperature which falls below 27°. Trees exist occasionally with us, but they never show a trace of the beauty they do in countries sufficiently warm for them.

NOTES AND QUESTIONS—VARIOUS.

Apricot Branches Dying.—Mr. Gilbert's advice upon this subject (see p. 295) is, doubtless, good; but, when the seedlings are raised, would they be of any value? Does not the seed produce, as a rule, fruit inferior to that of the parent?—A. D.

Variegated Common Laurel.—This we cultivate in our Nurseries. In some soils it retains its creamy markings well, but in rich alluvial soils it often, I may say generally, reverts to the normal green colour. Peat soils generally preserve variegation better than any other.—J. SCOTT, Merriott.

Maranta tubispatha.—Can you tell me whether or not this dies down in winter?—K. [Yes; it belongs to the deciduous section of Marantas, and, therefore, naturally dies down in winter.—B.]

Victoria Regina Violet.—Another year's experience of this fine Violet enables us to recommend it with confidence as one of the largest, hardiest, and sweetest Violets in cultivation; almost as long-stalked as the Czar, and decidedly sweeter.—"Villa Gardener."

Brugmansia lutea.—There is now in flower in the conservatory at Hatfield House a magnificent plant of this rather scarce Brugmansia. It is in the finest possible health, and its bright yellow flowers contrast well with the dark green foliage. It is a plant worthy of extensive cultivation.—E. BENNETT.

Earliness of the Pink Primrose.—Many are not aware of the earliness of the coloured varieties of the common Primula over those of the common pale forms. In early spring several of these are in flower in the worst kind of weather. This season the pink varieties have been in flower in March, while the common yellow are hardly open in April.—"Villa Gardener."

Aubrietia Eyerii.—This fine variety, exhibited by me the other day at South Kensington, was raised by Mr. Stuart, gardener to Mrs. Eyre Crabbe, of Glen Eyre, Southampton. It is a robust growing kind, and has larger flowers than those of *Aubrietia græca*, and of a much deeper hue of colour than that of *Campbellii*; indeed, they are richly shaded with violet, and, as it is a free bloomer, it makes a beautiful spring bedding plant.—A. DEAN.

Retinospora plumosa Indoors.—Among the eight or nine kinds of *Retinospora* with which I am acquainted, this is perhaps the most beautiful, and being slender and graceful in growth, it is well adapted for conservatory or hall decoration. Indeed, more Coniferous plants, when grown in pots or tubs, are suitable for this kind of work than many imagine.—J. MURR.

Button-hole Flowers.—Some of the small white-flowered Narcissi, especially *N. papyraceus* or "Paper white," look well mixed with the lovely blue *Scilla sibirica* and a bit of any fresh green Fern. *Boronia serrulata* is one of the best of all bright rosy-coloured flowers now available for such bouquets; its little tufts of four or five tiny flowers are admirably adapted for grouping along with white Hyacinth pips or with a small white Tea Rose.—B.

Hardiness of Selaginella denticulata variegata.—This is equally as hardy as the green form. It possesses the peculiarity of entirely changing to a silvery whiteness in a perfectly cool house in winter. A long line of it, in a north house here, where frost is barely excluded, forms an edging to a Fern stage, and has this winter been very striking. In summer, it becomes green all but the very tips of the young growth, but changes again to white with the decrease of temperature.—W. D. C.

Shaking the Dead Flowers off Camellia Plants.—The practice of shaking plants, in order to dislodge unsightly or falling flowers, is very often carried too far, and is the cause of much damage. A well-laden Camellia, for example, covered with hundreds of splendid blooms, is often treated so roughly in this way that, in getting rid of the fading flowers, quite as many of those that are still perfect are injured, and many a plant in full flower is prematurely shaken out of bloom. Moreover, when a cut flower is required, the choice generally lies between a bruised one and a newly-opened bud.—CHEVALIER.

Propagation of Coprosma Baueriana variegata.—Now is a good time to obtain a stock of this fine-foliaged plant, as old plants of it will now be making young shoots, which I have always found to root most freely. I take the young tender tops about 2 inches long, cut them immediately beneath a joint, and insert them thickly in ordinary propagating-pans, well drained, and filled with a light sandy compost. I then place them in a bottom-heat of about 80°, and keep them close, shading when required; and I have never been disappointed with the result.—E. G. OTTEWELL.

Training Camellias.—This is a great mistake. The desire of young gardeners to have a large plant in as short a period as possible is no doubt the cause of the mis-shapen plants that are so frequently met with. I maintain that pruning, and not tying, is the most natural way of producing finely shaped plants; and, no matter what age the Camellia, this operation should be performed; every healthy strong shoot should be shortened, and the weak ones cut out. In eight places out of ten, if you don't find Camellias lean and lanky, you find them deformed and twisted into all sorts of shapes.—CHEVALIER.

Arrangement of Cut Flowers.—I saw the other day a device in this way, so simple and pretty that I made a note of it. It consisted of a circular piece of cork 6 inches in diameter, and a quarter of an inch thick, perforated with holes like the hose of a watering-pot. Into these the flowers were neatly arranged, and the cork floated in a saucer of water, where it formed a pretty object in the centre of a small table. For small flowers with delicate stalks, this plan answers well, and also where a low flat system of table decoration is required. Let me add that, for table decoration, the beautiful *Primula cortusoides amena*, when grown as a pot plant, does well.—OBSERVER.

Dendrobium fimbriatum.—When well grown this is one of the most ornamental of all spring-blooming yellow or orange-flowered Indian Orchids. A plant of it at Abney Hall, Cheadle, is just now furnished with fifty spikes, most of them bearing nine or ten flowers each, and some few even more. The crimson-blotched variety *D. fimbriatum oculatum* (*D. Paxtonii* of gardens) is even more beautiful than the species, because it possesses greater variety in colour. Both plants grow well in an ordinary plant stove, and under ordinary cultural skill seldom fail to bloom well. A plant of the crimson-blotched variety, bearing fifty or sixty spikes of bloom, was shown the other day at the Regent's Park exhibition.

Ixora-root Insects.—I have just lost a very fine *Ixora*, and find the roots a mass of warts, in some of which there is a small white egg. How is this to be avoided in future?—J. F. W., Henwick Grange, Worcester. [This is new to us. The galls are of the same character as those on Pea roots, but quite distinct, and the first step should be to get some more information about it. If our correspondent would isolate the plant (by covering it entirely by a muslin tent) and rear the insect from it we should then know with what we are dealing. If he is not an entomologist, he may not like to take this trouble, but perhaps he has some friend who will not grudge it, and, failing that, if he will send an infected plant to us, dying or living, provided the roots and galls are alive, we shall undertake the enquiry with pleasure.—ANDREW MURRAY.]

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE MOUNTAIN PRIMROSES.

OUR lowland woods and pastures are not more abundantly adorned with Primrose and Cowslip in spring than the valleys, and slopes, and pastures of a thousand mountain ranges with Primroses much smaller in stature and more vivid in hue. Indeed, I once stood in an Alpine pasture of several thousand acres, in which the vivid *P. integrifolia* was everywhere as plentiful as Daisies on a lawn. Many of the kinds we are accustomed to think rare in gardens abound in like manner in Alpine lands. Sometimes they haunt the mountain bogs like our own Bird's-eye Primrose, but, for the most part, they love the friendly shelter and moisture of the Grass and Alpine turf; in numerous cases, indeed, forming a turf with numbers of their own rosettes. Like many other Alpine plants, however, these, contrary to the generally received opinion, possess great power of adaptation to varying circumstances; and the most striking aspect of Alpine Primrose vegetation I have seen was on an enormous wall of vertical cliff, far up one of the valleys of the Maritime Alps. On this earthless scarp Allioni's Primrose grew in every narrow crack in the rocks, every plant bearing numbers of deep rosy blooms, which fell in showers at the base of the cliff. In some receding parts of this cliff the plants grew where, in many cases, they never had any direct rain; and in no case was there any earth discoverable in the chinks near the eye. The plant had probably adorned the lonely cliff for thousands of years, and it could never have had any protection from the snow in consequence of the erect character of the face of the cliff. Frequently, Alpine Primroses are so small that one blossom which wells up from the heart of the rosette, stained as richly as any Rose, more than covers the whole plant from which it sprung. Sometimes a high elevation produces this dwarfness, and we may see in the warm valley plants with leaves several inches long, which, on the adjoining mountains, are not an inch across; often, however, the kinds are naturally among the smallest of beautiful flowers, as in the case of the Scotch Bird's-eye Primrose and the Alpine *P. minima*; while, in the Himalayan region, in Japan, and in the Southern Alps they assume large dimensions, so far as development of foliage and stem is concerned; with the smaller species, however, always remain the greatest size and splendour of bloom. How may this varied and extraordinary loveliness be added to the charms of our gardens? For ages we have grown abundantly the commonest of the Alpine Primroses of Europe, *P. Auricula*, which thrives in many parts of the country as well as in its native home, and, in its more delicate and cherished forms, is grown by florists with frame protection. With the exception of this species, nearly all Alpine Primroses manifest impatience of our garden culture. The long season of growth, and, on the other hand, the not unfrequently severe droughts of our summers, are against them. There is, however, little difficulty in growing species akin in character to the common *Auricula* in free moist soil, and with annual division and re-planting of the tufts. The long season of growth and warmth of our lowland gardens induces a lanky habit of growth; and many of them, emitting roots freely from the little stems, and gradually becoming weaker at the base, soon perish if not divided rather frequently. This done, they seem to become, as it were, possessed of new vigour, and go on fairly well for another season. The necessity for this division, however, does not exist in elevated, exposed, and moist districts. Mr. McNab grows a considerable variety of the handsomer species, in frames, in the Edinburgh Botanic Garden, and they are generally easy of culture in pots placed in cold frames. On the properly constructed rock garden they grow freely, thriving most satisfactorily in rather poor sandy loam, though some kinds like moist peaty soil best. It is well to secure and grow abundantly well-coloured varieties of the Common *Auricula*, as few hardy plants are more beautiful than the varieties of this species, known in the trade as Alpines. They are precious rock-garden and border flowers.

The Himalayan kinds, in the way of *P. integrifolia*, thrive best in sheltered nooks in the rock-garden and Fernery, and when planted in such positions in deep vegetable soil, grow with great vigour. The little Scotch Primrose, certainly as beautiful as any other kind, grows freely and "sows itself" on the surface of a pan or pot of moist soil, even in London gardens, and the Bird's-eye Primrose is easy of growth in parts of the rock garden not liable to get very dry. V.

CULTURE OF THE PINE-APPLE FOR MARKET.

AFTER the long, dark winter that we have had, the Pine, like the Vine, is most affected in the leaves, which are narrower and longer at this time of year, but the fruit having been subjected to cool treatment during January and February, swelled rapidly in March, and the warm sunshine is finishing them off, with that bright clear colour so much sought after, which shows how essential light and air are, in order to perfect such fruit. Pines are grown here chiefly for market, and our fruit-cutting season commences about the middle of October, and finishes about the end of May. The first batch of suckers is taken off the old plants, potted into well-drained 7-inch pots about the end of May, and then plunged in a pit, which has been previously prepared by sifting the dust out of the old tan, and mixing new with it to make up the deficiency, working them well together, and allowing them to stand for a few days, to see that the mixture does not get too hot. The highest temperature that can be called safe is 85°. By mixing the new and old tan well together, the heat in the bed is more lasting, and for the first month we keep a closer atmosphere, with as little fire-heat as possible. If the weather should happen to be hot, we give ventilation early and gradually, keeping the atmosphere cool, and shutting up betimes in the afternoon, after a light damping with the syringe. In about six or seven weeks the suckers are well rooted, and are then re-potted into the 10-inch pots, in which they are to fruit; these are again plunged in the pit, and are kept closer for a few days, according to the state of the weather. Avoid giving any check to the roots. Sometimes suckers are allowed to remain in the same pots for months before they are shifted; but this is a great mistake. The growth of a Pine plant should never be stopped, from the time the cutting is struck till the fruit is cut. I prefer leaving the suckers on the old plant till within ten or eleven months of the time when I want them to show fruit. The largest and best plants are all put together at one end of the house for the earliest, and are kept growing through the winter—with as much air every day as the weather will permit—up to March, when more air and a drier atmosphere are maintained at the warm end of the house, and only sufficient water given at the root to keep the soil in a healthy state. This treatment, continued for a month, ripens the growth and gives vigour to the plant. As April comes in, when there is more light and sun, a close moist atmosphere is again maintained, and in about a month the fruit will begin to show. By closing early in the afternoon, at 90° sun-heat, and ventilating early, using as little fire as possible, but, at the same time, keeping the night temperature up to 65° and the day to 70°, the fruit will be ripe in October, November, and December. For the spring fruit, we keep the plants growing till June, when we give them a month in which to mature their growth; this causes them to show fruit during August and September, and then get through their blooming before the dark cold days come on. The soil I prefer is the top sod of an old pasture, not more than 2 inches in thickness, which should be of a light loamy character, and ought to be packed up in a narrow stack about two months before it is required for use. Pot the plants firmly, without using any kind of manure, and thus plenty of fibrous roots will be produced. With plenty of air and light sturdy growth will be ensured, and the fruit will be well thrown up above the foliage. Never shade a Pine at any time. Shading may always be dispensed with if sufficient air be given early. The water used should always be of the same heat as that of the plunging material, which should never be allowed to fall below 70°, and sufficient should be given each time to thoroughly wet the soil. Clear water should be used till they show fruit; then weak liquid manure made from either sheep or cow dung, and used when freshly

made, as much of the ingredients mentioned being put in at every watering as will give it the colour of pale ale. Guard against over watering, especially in winter. JAMES SMITH.

Waterdale, St. Helen's.

New Potatoes at Christmas.—Mr. Calvert (p. 335) virtually asks how the Potato disease may be guarded against. I, for one, do not know, unless glass be used, and then the matter becomes simple enough. The last time I wrote on the subject I think I mentioned that the disease had so often taken me by surprise, that I had determined for the future to use glass, and I will relate how I obtained mine, and how I used it. Looking round me, I found sixteen old window-sashes, each about 4 feet square. Having constructed my pit with planking, I fitted in the rafters, and the sashes were laid ready to hand. After filling up the pit with leaf-soil, together with a little loam, my Potatoes were planted on the 16th July, the seed having been kept for over a year. As there is an acknowledged difficulty in getting new Potatoes to vegetate so early, I took the precaution of duly airing the pit until the tops of the plants touched the glass, when the sashes were tilted back and front. Not one drop of water was given at any stage of growth. The result was that for two months—December and January—I had a full supply of excellent new Potatoes for table use. When the crop was over I put a few fresh leaves into the pit, and fresh soil to the thickness of about a foot, and then replanted half the pit, on January 10th, with Ashtops. On the 21st inst., I was again rewarded with a crop of fine new Potatoes; I have, therefore, from the same pit, been able to obtain two crops a year of the young tubers of this most useful of all vegetables. My practice when planting in spring is precisely the same, except that I make use of matting to exclude frosts; whilst, for the winter crop, I fill the frame inside with Fern, which keeps the plants warm and dry. No moisture whatever that I know of is given these frame Potatoes. The varieties I use are Ashtops and Early Handsworth—the former I like best both for quality and appearance.—R. GILBERT, *Burghley*.

Osborn's Forcing French Bean.—I quite agree with Mr. Nisbet's opinion of this variety (p. 245). I sowed it on Feb. 10th, and gathered the first dish of Beans on April 3rd. At the bottom of 12-inch pots I first placed a piece of crock and a considerable quantity of dried horse-dung and then filled the pot half full with a compost consisting of three parts of good fibrous loam and one part of rotten dung, and in this I sowed the seed. When they were well up I filled the pots with the latter compost, leaving in each pot four plants, and on these attaining a height of 9 inches they branched out from the bottom, every point being covered with flowers, which completely stopped their growth. I have neither pinched them nor staked them, which is a saving of labour. On each plant there is an average of fifteen or sixteen Beans; those which I gathered on April 3rd measured 4½ inches in length, but at the present time there are plenty 5 inches long. Of their flavour the highest opinion is expressed.—R. H.

The Best Time for Planting Potatoes.—There is some difference of opinion on this subject. The opinion of such an observant authority as the late Mr. Thomas Andrew Knight is generally considered of some value on such matters, but I doubt if he will be generally believed in the matter of Potato planting when he says:—I have uniformly found that to obtain crops of Potatoes of great weight and excellence, the period of planting should never be later than the beginning of March. This opinion, too, is endorsed by the late Mr. Robert Thompson, of Chiswick, who says that if planting can be done by the end of February so much the better. Now, with all respect to these authorities, it is safe to state that their opinion is not borne out by facts. For the general crop planting, April is the month; most crops are put in some time between the beginning and end of this month. In some parts of Yorkshire field planting is often not finished till the first week in May, and the crops are always excellent and much better than they would be if planted in March. As an experiment, I once planted a quantity of early and second early kinds at the end of February; the result was the poorest crop I have ever had, for many of the sets perished by rotting in the ground, and this is my general experience. Since then I have never planted the main crop of second early and late sorts till April, conducting operations only when the soil is in good condition, and I am always well satisfied if I get such as Regents and Paterson's Victorias into the ground by the end of the month. From years of experience I find that late planting ensures by far the best crop, and that is of some importance; the plants generally escape the late frosts. The Potato will hardly vegetate until the soil is warm enough to excite Scarlet Runner Beans. I therefore cannot see any advantage in spring planting being commenced sooner than April.—J. S. W.

NOTES OF THE WEEK.

— ONE of the most beautiful features yet introduced to our park gardens has been visible for the past week or two near the Serpentine Bridge. It is a crowd of Daffodils beside the water, and surrounding the Rhododendron beds. They remind one at once of Wordsworth's poem, which we print in another column (see p. 344). There are also some naturalised in the Grass on the site of the late Mr. Mann's old garden at the Kensington corner of the gardens. We hope that these plants may be allowed to increase and multiply in the positions which they now adorn so well, for few plants are better suited for the decoration of outlying portions of the unmown lawn than golden Daffodils.

— MR. GUMBLETON informs us that *Embothrium coccineum* is now showing bloom in his shrubbery at Belgrove, Queenstown. The flowers resemble those of the scarlet Honeysuckle.

— GRAPE HYACINTHS are now in great beauty in the different nurseries about London. The differences in their beautiful and delicate shadings are well seen when the various kinds are grown in strong tufts and in beds.

— A PRIVATE meeting of the Exhibition Commissioners and the Council of the Royal Horticultural Society is said to have been held at Lord Granville's last week. The various points at issue were discussed, and it is believed that the decision come to was that the Society's lease of the gardens at South Kensington was to be given up and a fresh one granted at a reduced rental. The Society's financial claims against the Commissioners and the question of a skating rink at South Kensington, were also discussed, but no decision on these points was come to.

— THE "Pall Mall Gazette" says "the Royal Horticultural Society is deeply in debt, cannot pay its rent, and in the opinion of experts is not over-diligent in promoting the interests of horticulture. In fact, the garden at Kensington is simply a pleasant resort for children and nursemaids on ordinary days, and for young ladies and their attendant young gentlemen on Saturdays and Sundays. It was lately proposed to add a skating rink to the other attractions of the gardens, but here the patience of the lessors gave way, and it was settled that if the inhabitants of Prince's Gate and Queen's Gate wish to amuse themselves in this way, they must do so on ground of their own, not on ground which in fact, though not in name, belongs to the nation. It must in the end become a question whether an estate, which is probably undervalued at £300,000, cannot be made to minister to the public enjoyment more effectually than by being leased at a nominal rent, which is not paid, to a society of which the principal object is to maintain an agreeable lounge for a particular district of London."

— ANOTHER view of the Royal Horticultural Society.—Mr. Gordon's questions to Mr. Cross in the House of Commons on the 20th inst., respecting the estate at South Kensington which was purchased by the profits of the Great Exhibition of 1851 are appropriate (says a "Birmingham subscriber to the Exhibition of 1851" in the "Times"), just now, when it is generally known that the Commissioners, represented by Earl Granville, Earl Spencer, and Dr. Lyon Playfair, are in communication with the Royal Horticultural Society on the subject of the bankrupt state of that body. The published accounts of the Society show that it has paid off only a few hundred pounds of the £50,000 which it borrowed by debentures in 1858; that it has only paid two rentals to the Commissioners for the gardens which rentals the profits of the International Exhibition, and not the profits of the gardens, enabled the Society to pay; that the Society is under long and heavy obligations to life subscribers; and that the Society owes heavy debts for the annual working expenses, including payments for prizes at shows. I do not enter into the details of the quarrels of the Society itself since the Duke of Buccleuch's Council was displaced by Lord Bury's, because my object is to call attention only to the public interests in the estate held by the Horticultural Society. Here is a property virtually belonging to the public, and held as a public trust, from which the public derive no benefit. The 20 acres of land held by the Horticultural Society under a lease, which will terminate about 1893, represent a value of several hundreds of thousands of pounds—some say even £500,000. The Society cannot pay even £500 a year for it, and the public at large are excluded from the enjoyment of it, while it cannot be said to fulfil the purposes for which it was purchased. As one of the public, I do hope the Commissioners will duly consider these facts when they discuss the relations between themselves and the Horticultural Society.

— WE hear from Messrs. Veitch & Sons that Mr. Marks, late of Firsleigh House, Isleworth, has been appointed gardener and bailiff to his Royal Highness Prince Christian, Cumberland Lodge, Windsor Park.

THE INDOOR GARDEN.

BEST SINGLE AND DOUBLE FUCHSIAS.

IN order to have well grown Fuchsias for conservatory decoration, cuttings should be made of the earliest shoots put forth by old plants of the previous year after they have been put into gentle heat in early spring, and where it is necessary to get plants from nurseries they should be obtained at once in large 60 or 48-sized pots—good plants, 8 or 9 inches at least in height. If cuttings are relied on, they should be placed in shallow pans in a bottom heat, in plenty of silver sand, or pricked out on a hotbed, where they will usually strike root in the course of a week; and, as soon as rooted, they should be put singly in thumb pots, using one-half well decomposed leaf mould, and the other half good rich yellow loam, with enough of silver sand to keep it sharp and slightly gritty. As soon as the roots reach the sides of the pots another shift should be given, for the great aim of the cultivator at this stage should be to keep the plants growing vigorously and quickly. When the second shift is given the plants may be removed to the greenhouse, keeping the house rather close for a week or ten days, when more air may be given. When the plants have attained the height of 6 inches pinch out the top of the main shoot, in order to make them branch out; and, in the course of another fortnight, the points of all the other shoots should be pinched out, except the leading one, which must be encouraged to grow to a height of 6 or 8 inches, and then again stopped. The great object of this stopping is to keep the plants bushy at the bottom, and, by judicious pinching back, they may also be kept bushy and pyramidal in shape, the best form in which the Fuchsia can be grown either for show or for decorative purposes. Supposing the season to be about the middle of the present month, the plants should be syringed morning and evening, and they should be re-potted as they advance in growth; and again the points of such shoots as may be growing too strongly should be pinched out; for, if neglected, they impair the symmetrical shape of the plants. As the sun gains strength the plants should be shaded about mid-day; and, in bright weather, they may also be frequently syringed, which will greatly accelerate their growth and keep them free from green-fly. Too much stress cannot be laid on the importance of judicious and timely pinching if the plants are to be grown into good specimens for exhibition. It would be well if the cultivator aimed at this, even if his plants were required only for conservatory decoration; for, if this were done, we should much more frequently meet with good specimens of Fuchsias in greenhouses than we now do. At first every flower should be pinched off in order to throw all the strength of the plants into the growth; and the constant pinching just referred to is for the purpose of giving the plants that even and unbroken appearance so requisite in symmetrical specimens. Presuming that by this time the plants have reached a height of from 2 to 3 feet, and are required for exhibition in July, cease taking off the flowers, allow the shoots to grow, and discontinue re-potting at least six weeks before the day of exhibition, by which time they will be full of bloom and fit for showing. Plants treated in this way may be had in bloom by the end of May. Supposing there is another exhibition in July or early in August at which the cultivator may be desirous of exhibiting, the course he should adopt on bringing his plants home from the first show is to pick the flowers off, and let the plants stand in the greenhouse a day or two to recover from any

check received during the transit to and from the exhibition; then they should be re-potted, and allowed to grow all over the surface, and brought into bloom, sooner or later, according to the time when the second show is to be held. From the end of June and onwards the house in which they are placed must have air day and night, and the plants should be syringed four or five times a day in hot bright weather. This not only keeps the atmosphere about them cool, but also moist, and it is discouraging to insects. Great advantage will now be found in covering the surface of the pots some 2 inches in thickness with well-decomposed cow manure, and every precaution must be taken to prevent the access of bees to the flowers, when air is given, by protecting them with tiffany, or some such light material. Under some such system of culture as this Fuchsias may be had in fine and continuous bloom from May to November. The plants should then have a season of rest previous to being started into growth for another year, when such plants, by skilful treatment, may be grown to almost any size. The following is a short list of good varieties:—Fuchsias having red tubes and sepals, and purple or plum-coloured corollas; Enoch Arden, War Eagle, Try me O, J. F. McElroy, Lizzie Hexham, and Gazella. Fuchsias with white tubes and sepals, and scarlet and pink corollas: Mr. J. Lye, Minnie Banks, Lustie, Lucy Mills, Arabella (improved), and Lady Sale. The same, but with rose or lavender-coloured corollas: Father Ignatius, John Bright, and First of the Day. Other good varieties are Killiecrankie, Prince

Alfred, and Lady Heytesbury. The foregoing are all single. The following are the best double varieties, both light and dark: Mrs. H. Cannell, Mrs. Ballantine, Avallanche, Alpha, Purple Prince, Marchioness of Anglesea, Marksman, Grand Duke, and Blue Beauty. It may be added that, for window culture where there are no proper appliances for propagation, the cuttings may be struck in pots only half filled with soil, which should be of a light sandy character. This will allow the cuttings, when inserted, to be covered over head with a flat piece of glass, and, thus snugly situated below the rim of the pot, they soon take root, when they

should be potted off separately and grown on in as hardy a manner as possible, so as to enable them to withstand the exposure to which they must necessarily be subjected. Quo.

Williams's Maiden-hair Fern (*Adiantum gracillimum*).

WILLIAMS'S MAIDEN-HAIR FERN.

(*ADIANTUM GRACILLIMUM*.)

OF all the Maiden-hair Ferns now in cultivation, none are more valuable and useful than the wedge-leaved Maiden-hair (*A. cuneatum*), which has hitherto been, perhaps, the most popular of all cultivated Ferns; its fronds are used by Covent Garden florists by the thousand every week in the year. Its chief claim, as a decorative plant, is mainly owing to its free habit of growth and the lace-like tracery of its fronds. The plant, which we now illustrate, is also a free grower, and, at the same time, is unsurpassed in delicate grace and beauty; indeed, its fresh green fronds resemble the lightest filigree work or the finest lace, and, in this respect, it is superior to *A. cuneatum*. *A. gracillimum* will always be especially valuable for furnishing fronds for bouquets, as their texture is so fine that they do not intercept the view of such flowers as may be placed below them, and, at the same time, impart a fairy-like lightness to the arrangements in which they are used. Some idea of the exquisite lightness of this plant may be obtained by a glance at our

illustration. It grows well in any ordinary plant-stove or warm greenhouse, the best compost being one composed of fresh fibrous peat, to which about one-fourth of fresh turfy loam and a little leaf mould has been added. The pot should be well-drained, and a liberal supply of water at the root and humidity in the atmosphere is beneficial when the plant is making its growth. B.

Salvia splendens.—This, as its name implies, is one of the most brilliant and showy of Salvias, and a plant which I can strongly recommend where showy flowers are prized for winter decoration. Although generally considered a greenhouse plant, being a native of Mexico, it requires rather more than ordinary greenhouse temperature to grow it in perfection, as the blooms do not expand freely in a low degree of heat, and are apt to damp and fog off. Like most of the Salvias, it is of easy culture; and if cuttings are put in at once, and carefully potted on when struck, they will make useful plants for blooming in October. To have the heads of bloom of large size, the plants must be grown freely on through the season without a check of any kind, and they thus get good strong shoots and ample foliage. To carry this out, the cutting should be potted off into 60-sized pots, in light, rich vegetable soil, consisting principally of thoroughly decomposed leaf mould and turfy loam. They should then be placed in gentle moist heat for a week or so, to give them a start. When well-rooted, nip out the top of the shoot to induce them to break and form close bushy plants. As soon as the side shoots show themselves they should be potted on in the same kind of soil, and afterwards placed in a close pit, or frame, till they start freely into growth. Gradually increase the air on all favourable occasions, so as to inure them to full exposure by the end of May, when they may be plunged out in an open situation to complete their summer growth. The plunging material may consist of half-rotten leaves, old tan, or coal ashes; but the former is preferable, being more open, a good non-conductor, and very retentive of moisture. The principal object in plunging plants is to prevent the action of the sun and air from drying and overheating the pots; and any light loose material, such as half-decomposed leaves, answers the purpose admirably. Plants placed out without plunging are subject to extreme and rapid changes of alternate heat and cold, with their attendant results—starved and stunted growth, red-spider, &c. All plants placed out of doors should, therefore, have their pots plunged, or shaded in some way. As soon as the pots containing the Salvias are filled with roots, they should be shifted freely on, if large plants are required. On dry sunny days the plants will be greatly benefited by having the syringe used upon them in the course of the afternoon or evening. It will be necessary to house the plants by the middle of September, giving them a light airy situation. They should then be kept in a temperature of 45° to 50°, where they will display their brilliant heads of bloom in full beauty, for at least two months. After flowering, most of the old plants may be discarded, as much room is thereby saved, and young plants are more vigorous than those a year old. *Salvia Heeri* is a valuable variety to succeed the above, and is one of the most effective plants we have for blooming during February, March, and April; and too much cannot be said in praise of this splendid variety. Although it has not the brilliancy of *splendens*, it rivals it in inflorescence; and, as it does not flower at the same time, it is equally desirable, and should be in every garden where gay flowers are wanted. *Salvia gesneriflora* is a fine spring blooming variety, but not at all equal to *Heeri* for freedom of bloom and general effect. It may be mentioned that neither of these bear forcing, and are soon spoiled if subjected to artificial heat. They must, therefore, be allowed to come on naturally in an ordinary greenhouse temperature.—J. SHEPPARD, *Woolverstone*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Paxton's Hoya Fruiting.—Can any of your readers inform me if *Hoya Paxtonii* has hitherto borne fruit in this country? I have succeeded in fruiting a plant this season, and the occurrence is at all events a rare one.—CHARLES TURNER, *Eastwood Hall, Notts*.

Maxillaria Turnerii.—I met with a small plant of this pretty Orchid the other day in the Wellington Nursery, and was delighted with its delicious perfume, which exactly resembles that of the common Honeysuckle. Another Orchid—the green-sepalled white-tipped *Pilumna fragrans*—has the odour of the Poet's Narcissus, and *Dendrobium (aureum) heterocarpum* has a perfume like that of Violets.—B.

New Camellias.—In your remarks upon Camellias I never saw any description of the two following superb varieties:—*Bianca Geraldine*, which is large, a creamy-white, and perfect in form; it has thick petals, and small yellow stamens appearing in the centre. The foliage and growth are very fine; it never loses a bud, but is not a free bloomer. Its blooms hang nearly three weeks. *Archiduc Etienne* has large blooms of light shaded pink, of finely reflexed form, with small curled petals in the centre; never loses a bud, blooms freely, and the flowers hang for a long time. The plant is of fair, but not of the best habit; but cannot be termed straggling. These are both very valuable kinds, and deserve to be better known. My Camellias are planted out, and I do not know how the above would behave in pots.—AMATEUR, *Birmingham*.

THE FRUIT GARDEN.

GRAPES WITHOUT ARTIFICIAL HEAT.

To those who have but a limited heated space at their command it is of some importance to be able to produce good Grapes, fit for dessert, with the protection of a glass roof alone. I will therefore describe, as briefly as possible, an amateur's Vinery, that annually finishes off excellent crops of Grapes, without the aid of any fire-heat, and with only ordinary care and attention. The owner is a retired builder, and consequently had a better knowledge of erecting the building than of the formation of borders and the after management of the Vines, a knowledge he had to acquire by hints from local gardeners, or the calendars of the horticultural press. The dimensions of the house, which might be enlarged or reduced without greatly altering the result, is 20 feet long, by 12 feet wide; the back wall is 12 feet high, the front wall 1 foot 6 inches. There are no front lights; but, under each rafter is a small ventilator. The lights are five in number, and measure 4 feet each. This, as anyone will observe, is a simple structure, but it is well adapted to the end in view, which is to obtain a sharp-pitched roof that can catch a maximum of sun-heat, and give the slightest amount of drip, thus securing a dry and buoyant atmosphere, in which the fruit may be kept in good condition, until the danger of severe frost renders it necessary to cut the remnant of the crop. There being no heating apparatus to exclude the frost, the house is useless for storing plants, so that the Vines are more thoroughly rested, as a very cool atmosphere is maintained, and the Vines do not get excited into growth sooner than those on open walls—a very important point, as the later they are kept from starting the less prospect there is of their receiving any severe check from the sudden variation of temperature which they would receive if started earlier. When they can be no longer retarded, which is usually about the beginning of April, the house is shut up close, and damped down as soon as the sun begins to decline, which process is followed until the Grapes begin to colour, when the damping is discontinued, and air is left on at night. It is also most important that ventilating should commence as soon as the temperature begins to rise, and be gradually increased until mid-day. The restrictive system of training is adopted, one rod being trained under the centre of each light, and every shoot stopped at one joint beyond the bunch. The foliage is not crowded, but every leaf gets the full benefit of sun and air. The result is from 30 to 40 lbs. of Grapes, that no professional gardener need be ashamed of, to each rod. The varieties are Black Hamburgh, Sweetwater, and Muscadine. The border, like the house, is simply but efficiently formed. The soil being naturally good was trenched; and several loads of turf, and a considerable quantity of bones added. No cropping is carried on over the Vine roots, which are also at liberty to extend into the vegetable quarters in search of food. The border is annually deluged with sewage manure, and although the Vines are so heavily cropped, the wood is strong and well matured. It is the system of converting Vineries into plant houses that brings the majority of insects to prey on the Vines. Do away with the cause, and you will have no reason to complain of these pests. I would, in conclusion, strongly advise amateurs to content themselves with old well-trying sorts that are proved to succeed with a moderate temperature, for, if they are ambitious of rivalling some of our great Grape growers in the growth of Muscats without heat, they may expect to record a failure.

Henham.

JAMES GROOM.

"DAMPING" FRUIT-HOUSES.

DAMPING is a term used to denote an important and every-day operation in the culture of hothouse plants, whether grown for fruit or flowers, and in most garden establishments becomes a considerable item of daily labour. It is a phrase with which every garden operative is familiar, and he looks upon the damping and syringing as an indispensable part of hot-house fruit culture, of which he would no more think of questioning the utility than he would that of regular ventilation. Nor is he far wrong in his faith in the syringe; but its universal employment for this purpose often leads to a practice

of indiscriminate damping, regardless of weather and other conditions, which is fraught with the worst results. Like firing, damping is a matter that requires judgment and discretion, for it is necessary to distinguish between the wants and habits of different subjects and their condition at the time and under the various circumstances of hothouse culture; otherwise the remedy may prove worse than the disease. The practice, we may be sure, has always been a concomitant of flues and hot-water pipes in hothouses, and was probably first suggested by the fact that, under natural conditions, damping takes place in the form of dew, which saturates every leaf and blade, and restores their flagging vigour after exposure to a bright sun and a dry atmosphere during the day. At other times the same end is accomplished by an overcast sky, which arrests radiation and evaporation, and thus permits the foliage to gorge itself with moisture from the roots, which can then pump up the supply faster than it is dissipated. In a hothouse, however—a Vinery, for instance—these conditions, so favourable to plant life, are entirely reversed; for there can be no dew under a glass structure heated with hot-water pipes, but rather an unnatural state of aridity, which would in the end be destructive to plants were it not counteracted, as far as is practicable, by syringing the foliage and sprinkling the borders and other dry surfaces, in order that the proper degree of moisture may be maintained as steadily as possible. But, however indispensable damping may be under such circumstances, it is obvious that it may easily be overdone in a close structure where the atmosphere is under our control. Dew is generally deposited after bright sunshine, when it is most needed, and, as a rule, does not rest more than a few hours upon vegetation. In other words the foliage is dry and in an active state of perspiration during the greater part of the twenty-four hours—a fact which should be constantly borne in mind, but is often overlooked; and most practitioners err, as they think on the safe side, by giving too much moisture. As a learner I was taught the still common practice of shutting up and damping and syringing copiously early in the afternoon—abating the supply somewhat on dull or wet days, but hardly ever discontinuing it wholly—damping again in the evening, steaming the pipes, &c., and syringing and damping again in the morning; and thus, with Peaches, Vines, &c., in early forcing, keeping the atmosphere of the houses partially saturated for nearly sixteen hours out of the twenty-four.

Injurious Effects of Damping.

Such treatment I have in most cases found to be productive of green leaves and an apparent luxuriance for a time, but the real consequences are weak wood and foliage, and generally impaired health, which ends in failure (partial or complete) in the course of time. This is no exaggerated picture, for such practises are inculcated daily among many of the rising generation, who carry with them wherever they go an unquestioning faith in copious and frequent dampings, until experience teaches them otherwise. I very seldom get a strange hand who does not, as a rule, look upon the syringe and watering pot as his inevitable daily companion, morn, noon, and night. Now, Nature is a tolerably safe guide in this matter. Dew, or the moisture we see in a condensed form upon out-door vegetation on a clear night, is sufficient to reanimate every leaf in a short time—in fact, it only promotes repose after the day's fatigue under the influence of light and heat—and no more is required. It is the same in a Vinery or Peach-house, &c. Give sufficient moisture to restore the flagging foliage and prevent evaporation from its surface during the night, and it is enough. Practically speaking, damping once a day, or at most only slightly in the afternoon and again in the evening, is quite sufficient for most kinds of fruit or plant houses, and that only on fine dry days. In dull and wet days it is not necessary at all, unless under hard firing. It is also a bad practice to reduce the ventilation too much at a time, as is often done in shutting up in the afternoon, and damp copiously at the same time. A sudden transition from drought to saturation is a decidedly unnatural and unhealthy state of things. I dare say many of your readers have noticed, with Vines that have been drooping under a bright sun, that the mere partial closing of the ventilator, which shuts in the moisture arising from the border, is sufficient to restore them in a short time. It is not a good sign, however, when fruit trees under glass flag on a sunny day; it is a sure indication of thin, weak foliage, produced by high temperature in a close moist atmosphere. It is doubtless necessary in forcing to economise the sun's heat, and this can only be done by shutting up early in the afternoon; but to effect this it is not necessary to close the ventilators entirely. The most rational practice is to begin by giving air gradually, as early in the morning as possible, and to reduce it at the same rate till the minimum amount is reached at dark; for the ventilators should never be closed altogether. In bright days sprinkling water frequently about the floors and passages is a good practice, as it keeps down the temperature, and lessens the

necessity of giving too much air in cold and dry though sunny days; but shutting up and syringing at the earliest possible moment after mid-day is neither necessary nor advisable. At dusk a copious damping may be given fearlessly, for by that time the foliage is prepared for it by reduced light and ventilation, in the same way that a gradually overcast sky prepares Nature for the "expectant rain." Here we neither wash nor dress either Vines or Peach trees as a preventive against insects, and we only damp once a day, in the evening; yet our trees will compare favourably for cleanliness with any that have been so attended to. The hygrometer is an instrument too seldom employed in our hothouses; indeed, plenty of gardeners do not understand its use. Occasional reference to it would show the state of the atmosphere, as regards moisture, under different circumstances. It would show that in a Vinery during a clear frosty night, when a high temperature is maintained, the amount of dryness is sometimes as much as 6°, 7°, or 8°—nearly as much as is sometimes indicated at noon during a dry day in April or May—and this when the air should be at the saturation point, or nearly so; for it must be understood that these figures indicate the actual amount of drought the foliage is being subjected to when it would, under natural conditions, be laden with moisture, with no evaporation. On the other hand, in a Vinery in which the temperature is allowed to subside considerably below the usual figure at night and little fire heat is used, I find the dry and wet bulbs are nearly equal, and, as might be expected, the edges of the Vine leaves are laden with dew drops. That conditions so dissimilar must produce widely different effects for good or evil on the plants is evident; and it is not to be wondered that there is so much disease and debility amongst the inmates of forcing houses. The greatest difference I ever noted between the dry and wet bulbs in a Vinery at noon was about 18°, during a droughty day, with open ventilators. The greatest difference I remember out of doors was in May, when I occasionally noted as much as 14°. It requires sturdy healthy foliage in a Vinery to bear up under such circumstances; it is this which tries the foliage of Vines so much about midsummer, and produces those blistered leaves which are so often complained of by Grape growers; and Vines or other fruit trees which have been pushed on under high night temperatures, and in a too moist atmosphere, are the least able to bear the strain.

Damping Melons.

Melons I have always found to be particularly sensitive in this respect, the leaves of early plants frequently crumbling up in April and May, or falling a prey to insects, just when they should be attaining their maximum vigour. This is owing to the high temperatures and continually saturated atmospheres to which the plants have been subjected in February and March, when the least amount of air can be given, and which produce thin flabby leaves, unable to resist bright sunshine and a free circulation of air later in the season. To prevent this state of things, damping upon short days and during dull weather should be reduced to a minimum, and an abatement made in the night temperatures. I lately found in our Melon-house, where no damping had taken place for twenty-four hours, that the difference between the dry and wet bulbs at night, with moderately hot pipes, was only 3°—a safe disparity, which proved that no damping was needed. The day following, during a spell of bright sunshine, the difference between the dry and wet bulbs rose to 14°, and this after we had dull weather; but no drooping was noticeable in the leaves, nor on our pot Vines in full leaf, neither having been pushed at night previously, nor kept too moist at any time. From experience of this kind I have come to the conclusion that, with hothouse plants, and especially fruit trees under ordinary circumstances, damping or syringing overhead is not needful except during the hours of darkness, and should not be practised at any other time, and that the temperature at the same time should be as low as is consistent with safety, to arrest evaporation, otherwise the moisture can remain only a short time upon the leaves. I know it is hardly possible to adopt the practice of syringing after dark, but with lower night temperatures a single dewing in the evening would be sufficient. It is a problem worth solving whether it is better to sustain by fire-heat a night temperature equal to that which a plant would enjoy in its native habitat during our long dark nights, or abate the temperature at these hours in proportion to the altered circumstances and situation. For example, is it better to subject a tropical plant to a temperature of 75° by night, when it has to be sustained at that figure by fire-heat alone, or allow it to fall, perhaps to 55° or 50°, and thereby secure that rest to the plant which it would undoubtedly enjoy in its native land, though subjected to a higher temperature? My conviction is that the latter practice would be attended with the best results. Of stove plants I shall not speak at present, but in the case of Vines and Pines such treatment is borne without injury, if not with positive advantage, leaving fuel

(an item of some importance) out of the question. I have on several occasions this season subjected Muscat Vines to a night temperature of 48° when just about coming into flower, without the least bad effects; and during the late cold weather Hamburg Vines with the berries set have been frequently as low as 50°, and both fruit and leaves are in perfect health and vigour. J. S. W.

FRUIT CULTURE IN QUEENSLAND.

REGARDING fruits, the "Queenslander" observes that the Fig will flourish in a great variety of soils and situations in Queensland, and is easily propagated from cuttings. Many European varieties have been imported here, and are under trial, such as Brown Turkey, Grizzly Bourjassote, a light-coloured, valuable fruit; Poulette, another dingy, pale-coloured fruit, excellent, and prolific; white Marseilles, greenish-white, a good bearer, and of luscious sweetness; Grosse Verte, large, pale-green, rich, and excellent, late, in wet seasons apt to crack, and not so prolific as some; Smyrna, very similar to the foregoing; large black Genoa, flesh red, abundant bearer, excellent in flavour; brown Ischia, medium, chestnut-brown colour, good in flavour, and prolific; white Ischia, rather small, good bearer, and very rich. If the trees, when of sufficient age to bear, are barren, but vigorous in foliage, they are given a moderate root-pruning in winter, which gives a slight check and produces fruitfulness. Then comes the Guava, a well-known and prolific fruit-bearing tree, which is readily propagated from seed or layers. The yellow is the largest variety, quickest grower, and very aromatic. The green is smaller, but better in quality. The purple (Cattley's) has small roundish fruit, of exquisite flavour when perfectly ripe. The fruit of all the species makes good jelly. Next comes the Custard Apple, which is a delicious fruit, and the tree thrives well, but has not been very extensively proved yet. The following are valuable, viz., Sweet Sop (*Anona squamosa*); tree, small; fruit, carbuncled outside; pulp, delicious. Rough fruited and smooth fruited—Very similar in size and habit of tree, which is large and vigorous, as also the fruit, which is larger than that of the preceding, and of excellent quality; but the smooth fruited appears to be the most prolific. The Date Plum (*Diospyros Kaki*) is found in Japan in almost countless varieties, being to the Japanese what the Apple is in England—an every-day useful fruit. It is found of all sizes, qualities, and seasons, some suitable only for the kitchen, and others indispensable for the dessert. Besides the Kaki and Mabolo, five varieties have been received recently from the Horticultural Society of Victoria, imported from Japan. As seedlings of the Kaki have been pretty largely distributed, these ought to produce quite a variety of qualities, as the fruit sports greatly from seed. The tree is easily propagated by grafting, or by root cuttings. The Litchi, or Leechee, is a valuable Chinese fruit, which thrives well here. The tree is a bushy evergreen, which bears abundance of exceedingly good fruit in clusters, or loose tapering bunches; it is propagated by means of its stones, which germinate as readily as Loquats; also by layers, or grafting on seedling Litchis or on Longans. The Chinese claim that they have several kinds of this fruit, but say that it is rather particular, if not capricious, in its choice of soil. The Acclimatisation Society have several varieties under observation. The Longan belongs to the same family as the foregoing, but its fruit is smaller and not so good, but the tree appears to thrive in a greater variety of soils and climates. The Loquat, though better known, does not commonly receive the attention which it deserves. It is generally raised from seed, and the trees thus obtained often produce fruit of very different qualities. There is ample scope in the case of this one fruit for the efforts of some persevering, intelligent cultivator to raise new varieties, and propagate desirable ones by grafting.

THE EFFECTS OF VINE-BLEEDING OVERRATED.

There are few things which a gardener dislikes more to see than his Vines bleeding freely. Yet it has always struck me that the injury done in this way is often over-estimated. When young, I had a lot of well-grown Vines which I intended to fruit in pots. These were cut down to a convenient length, and at once placed in heat. As might have been expected, had I had more experience, they began to bleed; and in spite of all I could do, they went on bleeding. I burnt the cut ends with red hot irons, and then covered them with melting wax; but this treatment had no effect. Paint would not touch the wet surface, nor anything else stop the sap from running. At last some one told me to try a Potato stuck on the cut end of the Vine; and this did in a great measure stop the flow of sap, which had continued many days; but only a short time before it would have stopped of itself, as the Vines were soon in leaf. In spite of all this loss of

sap, I never had Vines which bore a better crop of Grapes than these did. Then, again, I once had a Muscat Hamburg which was a great puzzle to me. It grew at the coldest end of a 60-foot Vinery; and though it was always pruned early—in fact, almost as soon as the leaves were off—and the house was only kept at greenhouse temperature during winter and spring, yet this particular Vine always bled badly at every place where it had been pruned. I never had any other Vine which acted in this manner, either in this or in any other house. Nevertheless, this Vine, when in fruit, was never considered inferior to the others, and it always carried a full crop. These cases have left an impression upon my mind that, however undesirable it may be to have bleeding Vines, it is not quite so dangerous a thing as is often imagined. Can anyone say if this sap has ever been analysed? We know that a Vine will store up sap in itself sufficient to put out shoots and leaves before the roots have had time to grow in spring; and that when this stored-up sap is expended, growth is suspended till the roots get into action. Now, if by bleeding, Vines lose this stored-up sap, it must be injurious to them; but when Vines continue to bleed, I think it can be little else than water passing through them. I do not know how a leadless Vine can make sap; yet we are quite sure that Vines lose, by bleeding, far more moisture than they ever contained at one time. Is it not probable that a bleeding Vine would sustain most injury soon after it began to bleed? Any loss of sap, we would think, must take place at that time; afterwards, I should expect to find the liquid little more than water, just as absorbed by the roots. What is the opinion of Grape-growers on this subject? J. W. PEARSON, in "The Gardener."

Seedling Apricots.—A neighbour of mine has a seedling Apricot covering a portion of the front of his house. The stone was planted more than twenty years ago, and for many years it has rarely failed in producing a crop, owing to its sheltered position under the projecting eaves of the building. It seems in flavour and appearance identical with the Moorpark, the parent. He has also another seedling, about four or five years old, flowering for the first time this season. I think Mr. Gilbert deserves the thanks of your readers for calling attention to this matter; in fact, the wonder is, considering how easily they are raised, and the comparatively short time before they bear, that seedling Apricots are not more plentiful; and not only Apricots, but also Peaches and Nectarines. There are, in most gardens, bare intervals of wall between established trees that might be turned to good account in this way, without costing a farthing; and, even if some of them were inferior to their parents, others might be superior. But I think, so far as I have seen, there is less variation in Apricots than in other fruits, when raised from seeds.—E. HOBDAV.

Varieties of Cranberry.—At the annual meeting of the New Jersey Cranberry Growers' Association, Dr. Brakeley said he had noticed the following nine well-characterised varieties of the common cultivated Cranberry (*Vaccinium macrocarpum*):—1. The Cherry—the common variety. 2. The same flattened at the extremities, reminding one of a cheese. 3. The Pear-shaped. 4. The same, uniformly small. 5. The Bugle, shaped like bead of this name; large and deeply coloured. 6. The same, but frequently cylindrical and uniformly light coloured. 7. The Cream-coloured, bell-shaped and uniformly small. 8. The same, in shape between the Cherry and Bugle. 9. White, frequently tinged with cherry. Mr. French mentioned the fact, as characteristic of the sale of berries, that a very bright mottled berry had found a ready market. He had shipped, with some doubt as to their popularity, several crates of these berries to the west, and there had been a demand for more packages of this description. White or cream-coloured Cranberries were also mentioned as occurring in cultivation in New Jersey.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Apple Trees Split by Cold.—A correspondent writing from Michigan, states that the long and severe cold weather has injured Apple trees badly. Some are split the entire length of the trunk through to the heart, and the crack on others opens nearly an inch at the surface.

Seedling Apricot Trees.—Referring to recent notes on this subject in THE GARDEN, permit me to say that, according to my experience, no reliance whatever can be placed on trees from seed, as they vary very much as to quality of fruit, and are generally small and comparatively worthless. Trees grown in warm and calcareous soils will seldom lose their branches. There is no such thing as preventing the decay of branches entirely, as it appears, to some extent, on the most suitable soils.—D. GUIHENEUF.

Protection of Fruit Trees from Birds.—At a time when fruit trees are blossoming, and when sparrows and bullfinches have commenced their annual raids upon them, we may, says the "Revue Horticole," make known a method of frightening away these diminutive plagues. This consists of limewashing the trees, and from the moment they are thus whitened the birds disappear, and there is no further occasion to dread their attacks.

THE FLOWER GARDEN.

THE WASHINGTON LILY.

(*L. WASHINGTONIANUM*.)

THE Lily illustrated (see p. 300) as *L. Washingtonianum* is not that species; on the contrary, it is a totally different Lily. The one figured I first imported in 1873, and introduced it under the name of *L. purpureum*. Shortly afterwards, seeing that an eminent authority, as regards bulbous plants, had catalogued it as *Lilium Washingtonianum purpureum*, and thinking that he might be right, although the bulbs of the two Lilies differed, and that possibly it was a variety, I also catalogued it under that name. Since, then, however, from seeing more of it, I have come to the conclusion that the two kinds differ materially—that, in fact, they are as distinct, one from the other, as *longiflorum* is from *Brownii*. Compared with *L. Washingtonianum*, *L. purpureum* has a different habitat, bulb, flower, and colour; but differs most of all in its growth, mode of flowering, and arrangement of the flowers on the spike.

The Washington Lily (*L. Washingtonianum*).

The accompanying is an illustration of the true *Lilium Washingtonianum*. Compare this with the figure at page 300, and you will perceive at a glance how different the two Lilies are. I also send a coloured drawing of a new Lily, *L. Bloomerianum oscellatum*, from Santa Rosa Island, that I imported last autumn for the first time, which, as may be seen, is a charming addition to this now popular family.

WILLIAM BULL.

DOUBLE DAFFODILS.

It is a singular fact that some Daffodils very readily become double; even change of soil and locality seem favourable to the production of double flowers, and in some parts of France, especially near Orleans, and also in Italy, near Naples, the different indigenous forms of *N. Pseudo-Narcissus* are more frequently found with double flowers than with single ones. Double-flowered Daffodils are not all sports of accidental origin, as is the case with Camellias and Azaleas, but may be raised from seed, a fact well known to the quaint old gardeners of the last century, one of whom, Hale, curiously enough, observes:—"The Varieties of *Narcissus* raised by Culture are much more numerous than the Species we have from Nature." The following varieties of *Narcissus* are probably never met with in a double state, or, if so, very rarely, viz.:—*Juncifolius*, *bulbocodium*, *pachybulbos*, *elegans*, *serotinus*, *Broussonetii*, *intermedius*, *Macleanii*, *biflorus*, *viridiflorus*, *calathinus*, *triandrus*, *dubius*, *gracilis*, and *canariensis*. The following frequently assume a double-flowered condition, viz., *N. Pseudo-Narcissus*, *incomparabilis*, *odorus*, *Jonquilla*, *Tazetta*, and *poeticus*.

N. Pseudo-Narcissus.—Of this variable plant we have four or five showy double forms, one of the most rare and interesting of which is the true double-flowered form of our common English Daffodil. This variety was well known to Parkinson, who figured and described it (1629) as *Pseudo-Narcissus anglicus fl. pl.*, or Gerrard's Double Daffodil. It has often been confounded with the common large deep yellow-flowered double Daffodil of our gardens and orchards, but it is quite distinct from all other double forms. The perianth segments are of a pale sulphur-yellow, and the duplicate

segments of the fringed crown are clear yellow, as in the wild form, but not nearly so deep as in the common double kind. The common double Daffodil of gardens is a form of Haworth's *N. telemonius* (which is very nearly related to *N. major* of Curtis), a form of *N. Pseudo-Narcissus*, having large deep golden-yellow flowers, with pale yellow perianth segments. It is a native of Spain, and the single form is much more rare in gardens than the double one; indeed, this plant and its ally, *N. major* (which is abundantly naturalised near Tenby, in South Wales), seem inclined to produce semi-double and double flowers nearly everywhere in cultivation. The common double Daffodil was known to Haworth as the Pale-pointed Double, and it is probably the same plant as that described by Parkinson as Mr. Wilmer's Great Double Daffodil. The largest of all the double-flowered Daffodils is *grandiplenus*, or Trade-scant's Great Double Daffodil of Parkinson, a large, thick, massive flower, with green-pointed segments among rich golden or orange-tinted coronal divisions. In warm seasons this is very showy; but, when the months of March and April are cold, windy, and wet, the flowers are plethoric masses of dingy green segments, which never open properly; this is a monstrous double form of *N. major*, or one of the other large deep yellow Spanish varieties. Another Spanish plant, *N. Pseudo-Narcissus cernuus*, having creamy-white nodding or pendulous flowers, produces two double forms of great beauty. *Cernuus plenus* is a full, open, Rose-like flower, the perianth and coronal segments being creamy-white, and the centre of the flowers have often a tinge of lemon-yellow in them. Sometimes the multiplication of parts in this and other double forms of *N. Pseudo-Narcissus* is confined to the corona, and then the result is a very handsome flower. In some seasons, however, the corona bursts open, and then the flower assumes a Rose-like aspect. *Plenus bicinctus* differs from *cernuus plenus* in having a double row of normal perianth segments, as well as a double corona. One of the most interesting of all the double-flowered varieties of the Daffodil is that figured by Parkinson as *Pseudo-Narcissus gallicus minor fl. pl.*, and by the late Dean Herbert as *Ajax Eystettensis*. In all the forms just mentioned there is a duplication of coronal as well as perianth segments, but in this the multiplication of parts is entirely confined to the perianth segments, which overlap each other in six regular rows, just as do the petals of a Lady Hume's Blush Camellia. This is one of the rarest of all the double-flowered forms, being seldom met with in our gardens, although evidently well known in the time of Parkinson, who figures and describes it very accurately in his "Paradisus" (at p. 107, fig. 4 and p. 105). An irregular form of the last variety is evidently alluded to by Hale at pp. 354-5 of his "Eden," as the

True Double Daffodil.

Double Lemon Daffodil, which he describes as "familiar in full Perfection in the Gardens of Holland, but, though not unknown to England it does not often show itself in its proper Lustre." And, he adds, "the segments are long, obtuse, waved at the Edges, and disposed in a wild and irregular manner, not as in many double flowers in a Number of Series." On plate 44, of the last-named work, Hale figures what he calls the Silver and Gold Daffodil (? *N. bicolor fl. pl.*), and, at p. 517, he says, "The petals are of a very delicate, shining, silvery-grey, and the Cup yellow. This is the natural colouring; but sometimes the yellow runs in light

Variegations among the grey, and often the grey in the same Manner spreads itself among the yellow; either way the Colouring is extremely singular as well as pretty." And, under the head of culture, at p. 518, he observes, "This rises from the Seeds of some of those large single Daffodils which we have observed before are the original Produce of the common wild English Kind," and, a few lines lower down, he adds, "The great Art to obtain these double and variegated Flowers is to sow often and largely."

N. incomparabilis (Great Peerless Daffodil).—Of this there are several forms, three of which are often well marked and distinct, viz., Orange Phoenix, a kind with white perianth divisions, among which the rich orange segments of the corona are shown off to good advantage. The common double form of old cottage gardens has yellow segments, among which are scattered the divisions of the deep orange cup. This last is popularly known as Butter and Eggs, a name doubtless suggested by the colours of the flower. The third is creamy-

white, with yellow coronal segments in the centre of the flower, and is known as the Sulphur Phoenix. All these forms are sometimes seen in a semi-double state, the cup in that case retaining its entirety, the multiplication of parts being confined within its radius. Hale gives an excellent figure of this species, which he calls the Nonpareil Daffodil, and, at p. 482, he says, "We have said it is a Creature of the Gardener's Art, and the same management which first raised, must preserve and may improve it. The Seeds which ripen freely should be sown in the manner we have directed for the other Narcissi, and the young plants treated with the same care. They will show a great deal of Variety; some Flowers will be larger, others smaller, some better coloured, others worse, and there will be some double, or, at least, semi-double. These must be separated (the largest and best coloured with the double and semi-double flowers) into a bed by themselves, the others planted to supply vacancies and give Variety in common borders. From the Seeds of the semi-double there may always be raised perfectly double flowers, and these, as well as the finest of the single, may be afterwards increased by Offsets." Parkinson, at pp. 68-9, of his "Paradisus," mentions four varieties of this plant, and two of them he describes as producing geminate or fasciated flowers, but no allusion is made to perfect double-flowered varieties. One white-flowered form he describes as follows:—"N. maximus griseus calice flavo, the Grey Peerless Daffodil—This Peerless Daffodil well deserveth a place among these kinds, for that it doth much resemble them, and, peradventure, is but a difference raised from the seed of the former, it is so like in leaf and flower, but that the leaves seem to be somewhat greater, and the six outer leaves [segments] of the flower to be of a glistening whitish-grey colour, and the cup yellow as the former, but larger." This last-named plant is *N. incomparabilis* var. *albus* of our gardens, and I have quoted Parkinson's description to show that Daffodils were commonly raised from seed two centuries and a half ago. This suggests the question, where are all the innumerable forms that cultivators of these popular flowers have raised during this lapse of years? Mr. W. Baxter informs me that *N. Sabinii*, one of the finest single forms of *N. incomparabilis*, has died out in the Oxford Botanic Garden. Does any cultivator possess this plant still, or is it lost to our gardens?

N. odoratus (Fragrant Narcissus).—Of this plant there are two well-marked double-flowered forms, not unfrequently met with in old-fashioned gardens. One has double rose-shaped flowers, two or even three on a scape, of clear golden-yellow colour, made up of coronal and perianth segments. This form, which is by no means scarce, may often be seen at Covent Garden and other flower markets in the shape of cut flowers. In another form, more rarely met with, the duplication is confined almost entirely to the perianth segments, as is the case with Herbert's *Ajax Eystettensis*. This singular form is figured by Parkinson in his "Paradisus," therefore it has been long known in gardens. The double varieties of *N. odoratus* are popularly known as Queen Anne's Jonquil, and it would be interesting to hear how and when the name originated.

N. Jonquilla (Common Jonquil).—The double form of this old plant is well figured by Parkinson, who, singularly enough, gives a very poor engraving of the single form. It bears two or three golden-yellow fragrant flowers on a slender, deep, glossy-green scape, the individual blossoms being considerably smaller than those of *N. odoratus*, and more pleasing in form. It is a common and well-known plant in gardens, and is valuable in the shape of cut flowers. This and the single form, when forced in pots, are useful both for greenhouse and drawing-room decoration during the earlier months of the year. A plant, which I suspect is a double form of *N. odoratus*, is figured on plate 38 of Hale's "Eden" as the Double Jonquille.

N. Tazetta (Italian or Roman Daffodil).—This is the most variable of all the species of *Narcissus*, there being at least fifty well-marked forms of it, only one of which—the "Double Roman"—is, so far as I am aware, found in a double state. This double variety is well known, and extensively cultivated in pots for early flowering. It is singular that we have only one double-flowered variety among all the numerous forms of this plant, and the precise kind from which this double variety sprang appears to be unknown. Mr. Barr, who, as is well known, has paid much attention to *Narcissi*, has a delicious fragrant white-flowered form with a rich orange cup, named *N. Tazetta* var. *japonica*; and this is supposed to be the single form of the Double Roman, although it looks very different, when grown in the open air, from that variety. The double kind varies from a perfectly double flower, consisting of a white perianth and deep orange coronal segments in equal proportions to a form in which the duplication is strictly confined to the corona itself, the normal number of perianth segments being present in their usual form. A deep yellow form is figured on plate 37 of Hale's "Eden" as the Double Oriental *Narcissus*, and Parkinson gives engravings of two forms at p. 85 of his oft-quoted "Paradisus," one of which bears four or five-flowered

scapes of large white flowers, having a crumpled or broken yellow cup in the centre. In the other form the duplication mainly consists of the white perianth segments.

N. poeticus (Pheasant's Eye).—Of all the double forms of *Narcissus*, this is the most strikingly beautiful, in purity and sweetness rivalling even the flowers of a *Gardenia*. The pure glistening white perianth segments are incurved, and a few crimson-edged coronal segments are interspersed among them at the base. In doubleness this plant varies in different soils; but it deserves to be extensively cultivated for the sake of its fragrant flowers, which open about the middle of May. As cut flowers they are very useful, and possess the advantage of lasting in good condition for a long time in water after being cut. Parkinson, in his "Paradisus," p. 83, describes three double-flowered forms of this species, and at pp. 84-5 he describes and figures a double-flowered form seemingly intermediate between *N. Tazetta* and *N. poeticus*. In his engraving, which represents a four-flowered scape, the Rose-like flowers are shown as large as a bronze half-penny, and this he calls "*Narcissus chalcidonicus fimbriatus multiplex polyanthos*, the Great Double Purple-ringed Daffodil of Constantinople." In his description he quaintly contrasts it with the Double White Daffodil of Constantinople (or Double Roman) as follows:—"This Daffodil differeth very little or nothing in leaf from the former; the only difference is in the flowers, which, although they be double and bear many upon a stalk like unto them, yet this has the pieces of the yellow cup tipped with purple, as if they were shread or scattered among the white leaves, whereas the other hath only the yellow without any show of purple tips among them; the smell of this is as strong as any other." This curious and desirable form is now, unfortunately, lost to cultivators. It was doubtless a double-flowered form of one of the hybrid or intermediate varieties of *N. poeticus* and *N. Tazetta*, which we know exist in a wild state. Dr. Henon, who carefully studied the French *Narcissi*, says:—"The station of Lattes, near Montpellier, is remarkable in that it offers many species mixed in the same meadow." These species are *N. poeticus*, *N. Tazetta*, and *N. biflorus*, all of which are connected by a series of hybrid or intermediate forms.

The above are all the double Daffodils with which I am acquainted; but there are doubtless others, and of these some account would be acceptable. B.

Coleus Chameleon.—The most remarkable *Coleus* now in cultivation is the variety called Chameleon. The rich tints of pink, rose, green, white, and magenta which this plant presents make up, perhaps, the most extraordinary combination of colour to be found in any plant. During the early fall of 1873 this plant was (according to Mr. Chitty, writing in the "Rural New Yorker") introduced into England, and twice during the past summer specimens were exhibited before the Royal Horticultural Society, where certificates of merit were awarded it, and where it was so much admired as to form the centre of attraction on each occasion. *Coleus Chameleon*, recently re-christened in England *Coleus* Duchess of Edinburgh, is a most charming plant for outside decoration in summer. I have during the past summer and early autumn seen some splendid specimens, which were most brilliantly coloured and growing outside without protection from the sun. One plant was quite 4 feet high, and the colouring of its foliage was as rich and varied as any that I ever saw under glass.

DAFFODILS.

I WANDER'D lonely as a cloud
That floats on high o'er vales and hills,
When all at once I saw a crowd,
A host of golden Daffodils;
Beside the lake, beneath the trees,
Fluttering and dancing in the breeze.
Continuous as the stars that shine
And twinkle on the milky way,
They stretch'd in never-ending line
Along the margin of a bay:
Ten thousand saw I at a glance,
Tossing their heads in sprightly dance.
The waves beside them danced, but they
Outdid the sparkling waves in glee:—
A poet could not but be gay,
In such a jocund company:
I gazed—and gazed—but little thought
What wealth the show to me had brought:
For oft when on my couch I lie,
In vacant or in pensive mood,
They flash upon that inward eye
Which is the bliss of solitude,
And then my heart with pleasure fills,
And dances with the Daffodils.

—WORDSWORTH.

ROSE SHOWING v. ROSE GROWING.

I HAVE often wondered whether or not promoters of Rose shows take into consideration the proportion that Rose prizes bear to those offered for other garden produce that goes to make up an exhibition. So large a share of the funds do Roses monopolise that numerous deserving specimens of other kinds have to be passed over or, what is perhaps worse, receive so slight an acknowledgment as just to indicate that the judges have looked at them. Vegetables, as a rule, are considered beneath the notice of such meetings, and only fit to grace the tables of cottagers' shows. If it could be proved that Rose shows promoted improved systems of growth the amount given away in prizes for Roses would be well expended; but that is not the case. On the contrary, such encouragement only tends to perpetuate a system of growth wholly at variance with the natural beauty of some of the best Roses which we possess. The usual competitors are nurserymen who have hundreds of one and two-year budded plants to choose from, and a few gardeners and amateurs who convert their kitchen gardens into Rose nurseries, where Roses to supply blooms for competition may be seen like rows of inverted mops, one or two buds being left on each, and certainly anything but interesting, except in the eyes of the enthusiastic Rosarian who sees in the single truss elements of beauty which a more casual observer would only see in a fully-developed bush. Yet such is the custom, and year after year the best prizes go to "A," as it is well known that no one else can successfully compete under the circumstances. Such prizes are not offered for the most advanced system of Rose culture in general, but for single blooms, or clusters of bloom, at a given date. I have sometimes inquired of the secretaries of flower shows why so large a portion of the funds subscribed to encourage good gardening should be devoted to any one particular branch, to the exclusion of more useful objects, and the invariable reply has been that so much interest is always manifested in the Rose contest that it is considered to be the best part of the show. My impression, however, is that the amount of the prize money imparts to the contest between the rival exhibitors more excitement than admiration for the size or symmetry of the blooms. The question, therefore, arises, what are the good results of such shows? Rose-growing, in the true sense of the term, is not encouraged by such lavish outlay of money. I admire beds, banks, or pillars of Roses, but not standards, which, as usually seen, are the most unnatural-looking objects now tolerated in gardens; and, being usually planted in straight rows, it becomes almost a compulsory matter that they should be all pruned alike, in order that the heads may correspond as to size. The consequence, therefore, is that, like spur-pruned Vines, while some, as in the case of Hamburgs, are fruitful at every bud, others, like the Barbarossa, only produce wood. Nevertheless, while Rose-showing is encouraged as it now is, standards will continue to be the rule; and more graceful modes of growing the Queen of Flowers the exception.

J. GROOM.

Henham Hall, Suffolk.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Carpet of Flowers and Ivy.—Nothing looks prettier just now than Primroses coming through a sheet of Ivy round the more open parts of shrubberies. Old Hyacinth bulbs, Solomon's Seal, Ferns, and Violets all do well in a groundwork of Ivy. The shrubs are also much more healthy for the quiet enjoyed by their roots, and if one happens to show a bare stem the Ivy carpet has a remarkable effect of preventing it from looking unsightly.—A. Dawson, *The Cedars, Chiswick*.

Raising *Chamaepeuce diacantha*.—This interesting Thistle gives me considerable trouble, for I cannot get it up. I saw it at Battersea, and was so much struck with it that I made my mind up to make all my neighbours envious by its possession. I have got (to my thinking) the most artistic and elaborate designs for my flower beds for this year, and *C. diacantha* is the principal figure, but, as yet, the plant is obdurate. How am I to get it up? It is sown in a pan and placed in the propagating-house in a brisk growing temperature.—N. H. P.

Hardiness of *Sparaxis pulcherrima* in Northumberland.—As some seem to doubt whether this is quite hardy I may state that I have two plants of it that have stood the two last winters in my garden, as far north as Northumberland. During the late long and very severe winter they had no protection whatever, and now they are shooting up quite fresh. I may add that *Agapanthus umbellatus* has been planted out in my garden for many years without any protection in winter, and I have also seen it planted out much further north than here. Grown in the open air the blue of the flower seems deeper and more charming than when grown under glass.—G. F.

***Primula vulgaris* var. *Vesuvius*.**—The description and engraving which you gave of this beautiful but variable variety (see p. 319) are highly interesting. I first became familiar with it through a coloured figure on Plate 14 of Hale's "Eden or Compleat Body of Gardening," a valuable old folio work containing sixty coloured plates, published about a century ago. It is there figured as the "Polyanthous Primrose," and at p. 158 it is said to be a native of Turkey, and full directions are given with regard to culture. The concluding lines run thus:—"Let him [the cultivator] save the seed from the choicest of these flowers. In this way he will continue improving his stock, and by such Methods there is no Saying to what Excellence this kind may be raised." It may be added that the coloured figure represents the plant just as you have illustrated it; therefore the improvement suggested does not appear to have been effected.—B.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Kitchen Garden.—A sowing of French Beans may now be made on a warm border. It is not, however, advisable to put in many until the beginning of May, as they are liable to be injured by the weather. Neither is it advisable to sow at all until May, where the land is of a cold retentive nature; but in such localities, when this vegetable is particularly desired early, a fortnight may be gained by at once planting a couple of Beans in 48-sized pots, and keeping them under glass until the third week in May, after which there will be little danger from frost. At this early sowing do not cover the seed more than an inch, for if sown deeply and the weather becomes very wet, it will rot. The Paris Red Flageolet is one of the best of dwarf Beans, being good in quality and a heavy cropper. A few runner Beans may also now be sown in a dry situation; but do not at present risk too many. They are generally grown in rows 6 feet apart, on tall sticks; but it is not necessary that they should have sticks of great length, unless where these can be procured at little or no cost. Ordinary Pea-sticks, say 4 feet in height, will answer very well, pinching off the points of the shoots as soon as they get to the top of the support, and in this case the rows do not need to be more than 4 feet apart. They will, however, do well without any sticks. If the rows are planted 3 feet apart, the seed 9 inches asunder in the rows, and they are simply allowed to lay on the ground, they keep breaking out and flowering all through the season, and the quantity of Beans which they produce would not be credited by those who have not seen them grown in this way. A few more Turnips may now be sown, and for the general crop none are better than the Red-topped American Stone, already recommended for the earliest sowing. As with most other vegetables, it is much the best practice to grow Turnips in rows; sowing in this way takes a little more time, but any loss in this way is saved many times over by the facilities given for the use of the hoe in place of hand-weeding, which must in a great measure be resorted to where such crops are sown broadcast. Another sowing of the different sorts of Broccoli before advised should now be made; also one of Cauliflower, both Summer and Veitch's Autumn Giant. More Lettuces should likewise be at once sown; and now, and all through summer, these should be sown in rows where they are to be grown. The ground for them should be well manured; the rows should be 15 inches apart, the seeds put in thinly, and, when large enough to handle they should be thinned out to a foot or 15 inches apart. Another sowing of Broad Beans may be made where these are required late, but such as are put in now will not bear so well as those sown earlier. Pot Marjoram, Sweet Marjoram, Thyme, and Sage should now be sown on ground previously well prepared for them by fine raking, as owing to the seeds being so small they would be lost if the surface was rough; after raking, smooth the surface with the back of the spade, then sow the seeds and cover lightly with sifted soil. A little Beet may now be sown for an early supply, but do not yet sow the principal crop, as it is liable to run to seed if sown early. Sow in ridges 15 inches apart; where the soil is shallow it may be drawn into ridges about 6 inches high, and on these sow the seed, four or six together, in shallow holes a foot apart, covering them not more than half-an-inch deep. A little more Cabbage seed should also be sown, using on this occasion the small-growing Cocoa-nut, a kind which comes to maturity quicker than the larger varieties—these will form good heads for use all through the autumn, planted on ground on which the first Potatoes and other early crops have been grown. One of the principal things to be observed in a well-managed kitchen garden is to always have in readiness something to plant in the places of such crops as have just been cleared off. Keep the hoe going wherever it can be used when the weather is dry. The ground occupied by Gooseberries, Currants, and Raspberries should be well hoed before weeds attain any considerable size.

Flower Garden.—The beds not filled with spring-blooming plants should now be prepared for their summer occupants. The first thing to determine is what plants are to occupy each bed, which should be treated according to their respective requirements; for instance, Pelargoniums will not do well in over rich soil, which would cause them to run to leaf, instead of flowering freely; Verbenas and Calceolarias like it moderately rich, with an addition of new loam and leaf mould, if the old soil has become at all exhausted; for Alternantheras it can scarcely be made too rich; if the ground as far as their roots extend consists of one-fourth rotten manure they will attain double the size which they otherwise would do, and be much higher coloured than if planted in poor ground; for all the larger-growing, deeper-rooting plants get a good portion of the manure well down to the bottom, as deep as the soil is stirred; this is important, especially in dry situations, as, when roots have a store of food buried deeply below the surface, the plants receive such support as will enable them to keep on growing through a dry period in a way

which they cannot possibly do if their principal nourishment lies near the surface. Thoroughly pulverise the soil, but do not make it smooth on the top, for mere appearance sake, as, if for the next fortnight it lays sufficiently open to permit sun and air to penetrate it, it will be in a much better condition for planting than it otherwise would be.

Pits and Frames.—Sow in pots, in a gentle heat, some ridge Cucumbers for planting out. It is not good practice to sow these before this time, as they should not be turned out before the end of May or the first days in June; and, if sown too early, they get stunted before being put out, a condition from which they take some time to recover. A few more seeds of Vegetable Marrow may be put in, in case any mishap should befall those first sown. Give abundance of air to bedding plants such as Verbenas, Ageratums, Calceolarias, Heliotropes, and Pelargoniums. Where they are large and strong, the lights may be taken quite off in the middle of the day. All bedding plants in pots, especially if the latter are small and very full of roots, should be well supplied with water. In order to make sure of this, they will require looking to twice a day in sunny weather; for, if allowed to get very dry, they become hard and stunted, and are weeks, after being planted out, before they begin to grow freely.

Glasshouses.—Plants in the stove will now be in active growth. *Euphorbia jacquiniiflora* for winter flowering should be propagated, taking the young shoots off with a heel when six inches long and putting them eight or ten round the sides of 6-inch pots, two thirds filled with sandy loam, the remainder being sand; cover them with propagating glasses until rooted, then remove them singly into 48-sized pots. Plants of this *Euphorbia* that have flowered and been cut back when they have made young shoots a couple of inches long should be taken out of their pots, a good portion of the old soil removed, re-potted, and placed in the stove to make growth. Everyone possessing a house devoted to plants that require heat should grow the lovely sweet-scented *Stephanotis*; it is a general favourite, and does not require so much heat as many other stove plants; it will succeed where a winter night temperature of 50° is kept up, or even a few degrees lower. For amateurs I should advise its being grown in a large pot—15 or 18-inch—placed in one corner of the stove, and trained permanently on wires over the path near the glass; in this way it is in the best position for ripening its growth, without which it does not flower freely. *Bougainvillea glabra* will now be growing fast and shortly showing its flowers; assist it with manure-water every other time it is watered. *Clerodendron Balfourii* will also now require similar treatment. Like the *Stephanotis*, both these plants may be grown where there is not sufficient heat kept up for such subjects as *Ixoras* and *Dipladenias*, which do not succeed well unless in strong heat. *Rondeletia speciosa* is another good plant for amateurs to grow; it is easily managed, will succeed in either peat or loam, and is a free bloomer, producing neat red bunches of flowers from the point of every shoot. It is very useful for cutting, and the plant is not injured thereby. *Gardenias* should now be pushing up their flowers; do not give them either too much or too little water, for they are apt to shed their bloom buds. When cutting at this season, the flowers should be gathered when half open, or they lose their colour. Those useful summer-flowering plants, *Achimenes* and *Gloxinias*, will now be making free growth; give them plenty of light, with a little shade, in sunny weather. Attend well to *Gesnera zebrina* and *exoniensis*, for autumn flowering. Such things as *Caladiums*, *Marantas*, *Sphærogyne latifolia*, *Cyanophyllum magnificum*, and similar plants, will now require shade, or they will have a rusty appearance. Syringe freely in the afternoons, and keep up a moist atmosphere. Look well to the timely destruction of such insects as scale and mealy bug, which, if once allowed at this season to get ahead, are most difficult to eradicate, and they destroy the appearance of the plants. Ferns will now be making their principal growth, and will require some shade and plenty of water, but do not keep them too much darkened or too hot, or they become so soft as to be of little use for cutting. Nothing is more tantalising than to see the Ferns in a bouquet or a vase of flowers shrivel up in a short time after they have been arranged, which never need occur if they are not grown in a way to make them soft and tender. Close the stove early in the afternoon whilst the sun is still above the horizon, sun-heat being better, as well as cheaper, than fire-heat.

Variegated Laurels.—More than one of my Laurels have shown a disposition to put forth variegated leaves. From one of them in particular—a very old one—the terminal leaves are cream-coloured, and at first are delicate and pretty, but they soon degenerate and become rusty on the edge. Some of the lower leaves on the same branch are variegated, i. e., green splashed with white. I have layered some of the branches, but I scarcely expect to obtain a permanent variety from them. Mr. Davidson, the notice of whose experiments at Strathfieldsaye in your paper of the 10th inst. has led me to address you on this subject, may, I trust, be more successful.—C. B. H.

HENDERSON'S WINTER-FLOWERING AMARYLLIS.

(AMARYLLIS (HIPPEASTRUM) HENDERSONI COCCINEA.)

THIS is one of a superb group of varieties raised by Messrs. E. G. Henderson, from *Hippeastrum pardinum* in 1873. It is a great improvement on the parent type, which it much exceeds in size and richness of colour. In style of growth it is stately and robust, producing its bloom freely in a warm conservatory or greenhouse during the mid-winter months. Its large open-lobed funnel-shaped flowers, with a conspicuous green starry ray in the centre, are from 6 to 9 inches in diameter. The predominant colour, as will be seen by the accompanying illustration, is a rich velvety-maroon-crimson over three-fourths of the surface, finely contrasted with creamy-white. The crimson ground partially extends beyond the main body colour by diverging into separate crimson veins or lines, and also as a narrow belt of the same rich colour along the side margins, the intervening spaces being thickly sprinkled with crimson spots; beyond these each petal terminates in a broad ovately-oblong creamy-white tip, which imparts a bold and agreeable relief to the otherwise striking display of colour in this unusually showy variety. Its period of blooming under a much cooler atmosphere than that required for the tropical section of *Amaryllis*, renders it a valuable acquisition for decorative plant groups at a period of the year when plants possessing showy colours are most valued.

OPEN-AIR VEGETATION AT THE ROYAL BOTANIC GARDEN, EDINBURGH.*

FEB. 11.—The past winter has been remarkable for its severity, particularly during the month of December last, when the thermometer was observed on twenty-seven mornings at or below the freezing point. The lowest markings were on the mornings of the 15th, 23rd, 25th, 28th, 29th, and 30th, indicating respectively 17°, 18°, 17°, 13°, 5°, and 15°, whilst the highest night temperatures were on the 1st, 4th, 5th, and 6th, indicating 33°, 33°, 40°, and 38°. The united morning frosts during that one month amounted to 277°, being 31° more than was registered throughout the whole of the winter months last year, which was 246°, and of this number 36° only were recorded during the month of December. The last very severe frost experienced at Edinburgh was during December, 1860, when the united degrees of frost that month amounted to 267°; although the amount is 10° less than in December last year, the mischief done to vegetation was very much greater. The lowest point indicated during the winter of 1860 was minus 5°, being 10° less than was indicated during last December. After the disappearance of the frost on January 1, the weather for some time was dull, and comparatively little injury to vegetation has as yet been observed; had the weather been clear and sunny, vegetation, in all probability, would have shown greater damage. Some plants, however, have suffered considerably. A few points of the *Cupressineæ* were observed to be a little browned, particularly in low situations. The leaves of the Golden Queen Holly were also much discoloured. The Green Hollies, particularly the tree forms, have parted with a large quantity of their leaves. The *Phormium tenax*, or New Zealand Flax, as well as the *Cordyline angustifolia*, have suffered severely. Many of the latter plants have stood unprotected on the rock garden during the last five years, some having attained the height of 6 feet. During December, 1870, we had 168° of frost, and several of the *Cordylines* at that time were killed to the ground, but again pushed up from the lower portion of the stem, and afterwards became fine plants; hopes are, therefore, entertained that the injured specimens will all break out again, the plants being considerably stronger than they were when last damaged. In consequence of a coating of snow being on the ground during the severest frost, it will be some time before the mischief done to herbaceous vegetation can be known. During last month (January, 1875) the thermometer was fourteen times at or below the freezing point, indicating together 73°, while the previous January (1874) only indicated 32°. During the past month the lowest mark-

FENDERS' WINTER-FLOWERING ANARTHEUS.

A. fendersi coccinea. (Fort.)

ings were on the mornings of the 1st, 8th, 23rd, 25th, 26th, and 30th, indicating 13°, 26°, 28°, 29°, 25°, and 26°, while the highest morning markings were on the 10th, 11th, 14th, 16th, 19th, and 28th, indicating 38°, 39°, 39°, 42°, 42°, and 44°. Owing to the severe frost experienced during December, 1874, vegetation has been very much retarded. The following plants have bloomed in the open air during the month:

Jan. 15. <i>Corylus Avellana</i>	Jan. 21. <i>Veronica alpestris</i>
" 18. <i>Galanthus nivalis</i>	" 23. <i>Crocus susianus</i>
" " <i>Tussilago fragrans</i>	" " <i>Scilla præcox</i>
" 20. <i>Primula denticulata</i>	" 24. <i>Crocus Imperati</i>
" " <i>Erica herbacea alba vera</i>	" 25. <i>Hepatica angulosa</i>
" 21. <i>Hepatica triloba</i>	" 30. <i>Eranthis hyemalis</i>
" " <i>Leucojum vernum</i>	

On the first day of January this year the only open-air flowers that could be procured were *Jasminum nudiflorum*, four species of *Helleborus*, and *Gentiana acaulis*; while on January 1, 1874, no fewer than 138 specimens and varieties were collected in bloom.

March 11.—February has been exceedingly cold, easterly and north-easterly winds having prevailed during a considerable part of it. Snow set in on the 23rd and continued to lie during the remainder of the month, and up to the 11th of March snow was still to be seen on the northern slopes of the neighbouring hills. On twenty-one mornings the thermometer was at and below the freezing point, indicating altogether 75°, the lowest markings being on the mornings of the 4th, 5th, 10th, 12th, 17th, and 24th, indicating 21°, 16°, 20°, 27°, 28°, and 28°, whilst the highest morning readings were on the 1st, 2nd, 7th, 13th, 14th, and 16th, indicating 43°, 35°, 34°, 37°, 41°, and 35°. Owing to the long-continued and comparatively low temperatures experienced during the month, vegetation is very far behind; none of the plants noticed as being in flower in March last year are yet in bloom, and, with the exception of the *Crocus vernus*, *Bulbocodium vernum*, and *Mandragora vernalis*, no others noticed at the February meeting last year are yet out. Although the *Crocus* showed its first flowers on the 10th of February, very few have yet come forward, and even the *Snowdrop* can scarcely be said to be yet in perfection. At the March meeting last year specimens of *Ribes sanguineum* were shown in bloom, while this year the plants are still in their winter condition, the buds only swelling. Deciduous trees are also very far behind. The following is a list of the open-air plants as they came into bloom during the month of February:

Feb. 2. <i>Cyclamen coum</i>	Feb. 10. <i>Crocus vernus</i> and vars.
" " <i>Primula vulgaris rubra</i>	" 15. <i>Aubrietia grandiflora</i>
" " <i>Iberis gibraltaria</i>	" " <i>Primula purpurea</i>
" 3. <i>Galanthus plicatus</i>	" " <i>Tussilago alba</i>
" 4. <i>Rhododendron atrovirens</i>	" 16. <i>Knappia agrostidea</i>
" " <i>Daphne Mezereum</i>	" " <i>Saxifraga oppositifolia</i>
" 5. <i>Dondia Epipactis</i>	" " <i>alba</i>
" 6. <i>Bulbocodium vernum</i>	" " <i>Arabis procurrens</i>
" 8. <i>Erica herbacea</i>	" 28. <i>Mandragora vernalis</i> .
" 10. <i>Arabis albida</i>	

April 8.—The early part of March was cold, with easterly and north-easterly winds, which, with the cold of the previous months, have been the means of greatly retarding vegetation. Only on ten mornings was the thermometer at or below the freezing point, giving altogether 45° of frost, being 8° more than was registered during the month of March last year. The six lowest registrations were on the mornings of the 4th, 5th, 6th, 10th, 11th, and 12th, indicating respectively 27°, 24°, 28°, 25°, 24°, and 25°, while the highest morning temperatures were on the 8th, 22nd, 25th, 26th, 30th, and 31st, indicating respectively 45°, 42°, 46°, 45°, 42°, and 42°. During the month many open air spring plants have come into bloom; these being chiefly on the rock garden, a list of them is annexed in the order they came into flower. Many of the species are fully three weeks later in blooming than they were last year. The *Ribes sanguineum* showed its first flowers this year on the 30th of March, while last year it was recorded as flowering on the 3rd—a particular plant being fixed on for annually recording its blooming. At the February meeting I stated that several of the Conifers, particularly those of the Cupressineæ group, had suffered from the effects of the frosts experienced during the past winter. The few sunny days we had during the latter part of the month have told on several other species, but chiefly on those from the Eastern hemi-

sphere; several have been much disfigured, particularly the *Cupressus torulosa*, *C. cashmerensis*, *C. sempervirens*, *Thuja orientalis pygmæa*, *T. triangulare*, *T. gracilis*, *Cupressus Knightii*. The variegated portions of the *Cupressus Lawsoniana*, both gold and silver varieties, have been much injured, but no others of the *Lawsoniana* group, all the varieties being exceedingly healthy, and showing more flowers than they have done for many years. The *Abies* tribe in general have stood well, with the exception of the British seedlings of *Abies Menziesii* and the *Abies Douglasii*, both kinds being very much browned, particularly where growing in exposed situations; the variegated variety of the *Abies Douglasii* has suffered severely, both in exposed and sheltered places. Of the *Piceas*, the *P. lasiocarpa* is very much discoloured, as well as the British seedlings of *Picea nobilis*. Amongst the genus *Pinus*, *P. tuberculata*, *P. uncinata*, *P. insignis*, *P. brutia*, *P. patula*, and *P. Don Pedro*, are also browned, as well as the golden variety of the *Pinus sylvestris*. The arboreous vegetation of the deciduous class is this year very far behind. On the 31st of March, the Elm, Willow, Alder, Hazel, and Poplar, were in flower, and a few green leaves were to be seen on the Lilacs, Crab Apples, *Mespilus canadensis*, and some of the Thorns in sheltered situations; with these exceptions, all other trees may be said to be in their winter condition, although a slight swelling of the buds is here and there visible on the Planes and Horse Chestnuts. It is now evident that the *Cordyline australis*, *Phormium tenax*, *Gynerium argenteum*, *Arundo conspicua*, and *Tritomas* (particularly the *T. Burchellii*), have suffered severely, although none of them are killed. List of plants as they came into bloom during the month of March:

Mar. 1. <i>Primula purpurea</i> .	Mar. 19. <i>Saxifraga oppositifolia</i>
" 4. <i>Potentilla alba</i>	" " <i>bryoides</i>
" 6. <i>Sisyrinchium grandiflorum</i> album	" " <i>Iris reticulata</i>
" " <i>Tussilago nivea</i>	" 20. <i>Aponogeton distachyon</i> (in pond)
" " <i>Saxifraga Rocheliana</i>	" " <i>Scilla bifolia rubra</i>
" " <i>Leucocoryne alliacea</i>	" 21. <i>Erythronium grandiflorum</i>
" " <i>Doronicum caucasicum</i>	" " <i>Gagea lutea</i>
" 7. <i>Scilla bifolia vera</i>	" 22. <i>Corydalis tuberosa</i>
" " <i>Corydalis angustifolia</i>	" 23. <i>Scilla bifolia patula</i>
" 8. <i>Draba aizoides</i>	" " <i>Puschkinia scilloides</i>
" " <i>Primula marginata</i>	" " <i>Omphalodes verna</i>
" " <i>Sisyrinchium grandiflorum</i>	" 24. <i>Merendera caucasica</i>

" " <i>Draba cuspidata</i>	" " <i>Primula nivalis</i>
" 18. <i>Narcissus minimus</i>	" " <i>Draba altaica</i>
" " <i>Rhododendron præcox superba</i>	" " <i>Ribes sanguineum</i>
" " <i>Saxifraga oppositifolia grandiflora</i>	" " <i>Symplocarpus foetidus</i>
	" 31. <i>Symphytum caucasicum</i>
	" " <i>Hyoscyamus orientalis</i>
	" " <i>Erythronium Nuttallianum</i>

THE BEST MORTAR FOR GARDEN WALLS.

FROM a valuable little work on engineering,* by Mr. C. Graham Smith, we extract the following remarks on mortar making, which may be of use to gardeners concerned with the erection of buildings:—"To obtain good mortar, as much depends on the character of the ingredients and the manner of mixing them as on the goodness of the lime itself; it does not necessarily follow that because a lime is good the quality of the mortar will be good also; the best lime ever burnt would be spoilt by the custom, common among builders, of mixing with it alluvial soil and rubbish taken from the foundation pits of intended buildings. The sand should be hard, sharp, gritty, and, for engineering purposes, not too fine; it should be perfectly free from all organic matter, and with no particular smell; good sand for mortar may be rubbed between the hands without soiling them.

* "Engineering Papers." By C. Graham Smith, Stud. Inst., C.E., &c. London: E. & F. N. Spon, 48, Charing Cross.

The water also should be free from all organic matter, and on this account should never be taken from stagnant ponds. The presence of salt in sand and water is not found to impair the ultimate strength of most mortars, nevertheless it causes the work to nitrate, or, as it is commonly termed, saltpetre, which consists of white frothy blotches appearing on the face of the structure; it also renders the mortar liable to moisture, and for these reasons should never be present in mortar intended for architectural purposes, although for dock walls and sea works it may generally be used with advantage and economy. Sand is used to increase the resistance of mortar to crushing, to lessen the amount of shrinking, and to reduce the bulk of the more costly material, lime. Water is the agent by which a combination is effected, and as sand does not increase in volume by moisture, it necessarily follows that no more of the aqueous element should be employed than is absolutely necessary to fill the interstices between the sand, and render the whole into a paste convenient for use; and the greater strictness with which this is adhered to the more compact and durable will be the mortar." Two other papers, containing many excellent hints, one upon "Practical Iron Work," and the other upon "Retaining Walls," are contained in the volume.

TOBIN'S SYSTEM OF VENTILATION.

NOTWITHSTANDING the stress laid upon pure air by all sanitary reformers, the endeavours of architects to obtain the blessing have almost always made shipwreck upon the draughts which they occasioned, and upon the lowering of temperature which they have caused. These endeavours, moreover, have generally been guided by the entirely erroneous assumption that vitiated air, being heated, would not only ascend, but would also escape through outlets in the upper part of a chamber. When such outlets are made, the heavier cold air descends through them, pushing aside that which is lighter and warmer, often forcing it back through presumed inlet openings, and coming down in a stream, like water poured out of a jug, upon the heads of any unfortunates beneath. So completely has scientific ventilation been at fault that nearly every contrivance for the purpose, when applied to inhabited rooms, has produced chill draughts which were more unpleasant, and even more immediately pernicious, than vitiated air itself, and has induced the dwellers to stop up the openings with the least possible delay. The practical result has, therefore, been that our houses, and especially our rooms used for public purposes, are not ventilated at all. The means, however, of rendering the atmosphere of any chamber as pure as that outside the building, without improper lowering of temperature, and without the production of draught, has recently been discovered, and has been brought into practical application, by Mr. Tobin, a retired merchant, who lives in the neighbourhood of Leeds. Mr. Tobin's own account of the matter is that he was once watching a current of water which flowed into a still pond. He observed that the moving water kept together, and held its own, until its course was arrested by the opposite bank, when it curved gently round on either side, and was lost insensibly in the general body, which had its outlet for overflow at one side. He reflected that a current of air introduced into a room would act in precisely the same manner, keeping together until it encountered an obstacle, then mixing insensibly with the air around it, and compelling an overflow wherever there was an opening available. He saw that, if this were so, it would only be necessary to give the entering current an ascending direction, so that it would reach the ceiling without impinging on any person, in order to solve the problem of domestic ventilation. Experiments at his own house confirmed his anticipations, and led him to contrive methods, which he has patented, of carrying his principle into practice. At that time the state of the Borough Police Court at Leeds was, as, indeed, it had been for some time previously, a source of great perplexity to the Town Council. The Court is one of a series of rooms which surrounds the Town Hall, and the doors opening into it are three in number—one leading from a corridor which gives access to the public, one leading into the magistrates' retiring room, and one from the cells into the dock. Light is admitted only by a window in the roof, and in this skylight there is an opening, intended for the exit of foul air, but practically serving for the entrance of fresh air. The Council had expended between £1,400 and £1,500 on successive ventilation doctors, each of whom had left matters as bad as, if not worse than, they were before. The subject was one of continual comment in the local papers, but the council had begun to despair of a remedy, when Mr. Tobin offered to supply one. He suggested that the Council should pay him a nominal royalty for the use of his patent, and that they should pay the few pounds required for doing the work, leaving his own remuneration to their discretion when they saw the effect. These terms having been accepted, Mr. Tobin placed

under the floor of the court three horizontal shafts which communicated with the open air through a cellar grating. From these he brought eight vertical shafts through the floor at different points. These vertical shafts rise about 4 feet above the floor, and are each 5 inches in diameter. They have open mouths, and are placed out of the way in corners, or against the partitions of the court. From each shaft there ascends to the ceiling an unbroken current of the outer air, like a fountain, or like a column of smoke when the barometer is high. The current will support feathers, or wool, or other light substances, and has so little tendency to spread laterally that it can be made to influence half the flame of a candle, while the other half remains undisturbed. A person resting his cheek against the margin of one of the tubes feels no draught, and the hand feels none until it is inclined over the orifice. The effect was instantly to render the court as fresh and sweet as the external air around the building. The steady flow of the eight ascending currents constantly rinsed out, so to speak, the confined space, and washed away the effluvia of dirty people, and the products of respiration, as fast as they were liberated, forcing them out through the skylight opening which was previously only an inlet, but which was altered in a manner to facilitate egress. After three months' trial, and after all the magistrates for the borough had joined in the report, which expressed their entire and unmixed satisfaction, the Corporation voted Mr. Tobin an honorarium of £250, to express their sense of the benefit which he had conferred upon the town. They also applied his system to the council chamber; and their example was followed by some of the leading bankers and merchants, by the churchwardens of St. George's Church, and by the proprietors of the "Leeds Mercury," who have had every room and office in their spacious premises ventilated, under Mr. Tobin's superintendence, and who have expressed, in two or three descriptive articles, the entire success which has been obtained. The system of vertical tubes is necessary for rooms which have no side windows, or which have only a small window surface in proportion to their cubic contents. But Mr. Tobin at the same time contrived a cheap and simple method, by which vertically ascending air currents can be introduced through common window sashes; and this method will suffice for all ordinary living or sleeping apartments. Each of the openings made for this purpose is provided with a cover by which it can be closed at will; and they admit of a method of securing the sashes which affords almost entire security against burglars. A very competent authority has communicated to us his experience for eight weeks of a room containing 2,500 cubic feet, ventilated, under Mr. Tobin's direction, by four window openings which have an aggregate area of 30 square inches, but which are filled by layers of cotton wool to filter the entering air from dirt and moisture. The currents ascend in absolute contact with the glass, keeping so closely to it that they do not affect the flame of a taper which is held vertically in contact with the sash bar; although, as soon as the taper is inclined towards the pane its flame is strongly fluttered. In this way the air ascends to the top of the window, where it is directed to the ceiling and lost as a current, being no longer traceable by taper, hand, or fragments of down, although closing the window openings diminishes, in a marked manner, the draught up the chimney. Each opening, as already described, has an independent cover, and, without the wool, the four would, in cold weather, be too much for a room of the size specified. With the wool they do not perceptibly diminish the temperature, but they give a feeling of absolute out-of-doors freshness, which must be experienced in order to be appreciated. There is no draught anywhere, and the openings are not visible unless sought for, so that curious inquirers, who have remarked on the result, have been unable to find the inlets. Arranged as described, the openings are sufficient to feed a large argand table gas burner, and to sweep away entirely the products of its combustion; so that, when the room has been shut up, with the gas lighted and with a good fire, for three or four hours, persons entering it from the open air are not able to discover, except by the greater warmth, any change of atmosphere. A bed-room, ventilated in a similar manner, is as fresh when the door is opened in the morning as when it was closed at night. Mr. Tobin's experiments early led him to the conclusion that the prevailing notions about the necessity for carefully-planned outlets were fallacious, and that, if proper inlets are provided, the outlets may generally be left to take care of themselves. In order to test this he fitted two vertical tubes into a small room, which had a fireplace and a three-light gas pendant. He closed the opening of the fireplace, and every other opening into the room except the tubes, hermetically, and, shutting himself within, pasted slips of paper all round the door. He found that there was then no entrance current by the tubes. The room had no outlet; it was full of air, which his respiration had not had time to consume in any appreciable quantity, and no more could get in. He next lighted the three gas burners, and a steady entrance current immediately set in through the tubes,

and continued as long as the gas was burning. He waited nearly an hour without any deterioration of the atmosphere becoming susceptible to his senses, and with the currents steadily coming in and ascending in their customary manner. He then cut through the paper which secured the door, and left the room, shutting the door behind him. Returning half an hour later, he found the atmosphere still fresh. He next extinguished the gas, and the currents gradually died away, the original state of equilibrium or fulness being restored. This experiment, which has been several times repeated, seems to show that the external air will enter just in proportion as room is made for it by combustion or respiration, and that the rate of supply is essentially governed by the rate of destruction or demand. In the closed room the water produced by combustion would probably be condensed, and the heavy carbonic acid would sink to the floor. If the combustion continued indefinitely, the accumulation of these products would in time render the air "irrespirable;" but that time would be much longer in coming than is generally supposed, and, for all practical purposes, the chimney throat is everywhere sufficient as an outlet. The rationale of the matter appears to be that when the external air communicates with that of a room through a channel which terminates in a vertical shaft, an inward current is produced as soon as the air of the room is either rarified by warmth or partially consumed by respiration or combustion. This inward current is due to the pressure of the external atmosphere, which is capable of driving the entering air, in a compact column, to a considerable elevation. The whole pressure of the atmosphere is equal to rather more than 14 lbs. on each square inch; and this force would be all exerted if the chamber into which the air was to be driven was itself a vacuum. As it is, the pressure exerted will always be determined by the difference between the atmospheric density within and without the chamber; and hence, the more the internal air is rarefied or consumed, the greater will be the force of the entering current. It follows that the supply of air adjusts itself automatically to the demand, and that the inlets should always be sufficient for the maximum requirements of the room to which they are applied. However large they may be, they will not admit air in excess of the rarefaction or combustion of that which is already there; and, as rarefaction and combustion diminish, the number of cubic feet passing through the inlets in a given time will diminish in precisely the same ratio. In order to obtain an absolutely perfect result it is necessary to bear in mind that the behaviour of the entering current will be precisely like that of the vertical column of water sent up by a fountain, except that, as the ascending air is received in a fluid of only little less density than its own, it will mingle with that fluid gradually when the propulsive force is exhausted, instead of falling almost vertically by the action of gravity. But just as a fountain, if it encountered an obstacle while its column was still compact, would rebound from that obstacle with considerable violence, so the entering current of air, if it meets with an impediment prematurely, will be reflected as a draught. We have seen this very well exemplified in a room at Leeds, in which the construction of the windows rendered it necessary to make the inlets much higher up than usual, and in which, when the force of the entrance current was increased by lighting gas, a very distinct stream of cold air was reflected from the ceiling. To prevent such an occurrence, it is necessary to make the inlets so low down that, under all ordinary circumstances, the force of the stream will be expended before the ceiling is reached; and when, from any circumstances, this cannot be done, the current may be broken by strainers of wire gauze or other suitable material. In this, as in most other matters, some special adaptation of means to ends is required; and the arrangements for any given room must be planned by some one who has practical knowledge of the subject. The discovery that the pressure of the atmosphere can thus be utilised as a perpetual source of air supply without the aid of fans or other mechanical contrivances; the discovery that all draughts can be obviated by the employment of vertical entrance channels, provided only that their mouths are not too near the ceiling, and the discovery that improper lowering of temperature is prevented by the circumstance that the rate of entrance of air is governed by the demand, are truly comparable in their simplicity to the balancing of the egg by Columbus. Simple as they are, they are none the less calculated to add greatly to the public health and comfort. Their very simplicity implies a cheapness which places Mr. Tobin's contrivances within the reach of every one.—"Times."

The principle of ventilation by utilising the pressure of the atmosphere (says Captain Galton in a subsequent issue of the "Times") is not new. It has been applied in a number of ways in various public and private buildings; notably in the method of barrack-ventilation adopted in 1857 by the Barrack and Hospital Commission

under Lord Herbert's auspices. Nor is there any novelty in the method of introducing fresh air into a room by means of vertical shafts delivering the air into the room at a few feet from the ground. I used it in 1861 in the wards of the Herbert Hospital at Woolwich, and in other hospitals, but I utilised the fire-place for the purpose, placing it in the centre of the ward, with its flue carried under the floor, in order that in cold weather the fresh air should be tempered by the spare heat from the fire. Plenty of other instances might be cited. The principles of ventilation are well known. It is the application of those principles in special cases which causes the difficulty. The amount of current of inflowing air into a room will depend upon the facilities or arrangements for outflow, and *vice versa*. Therefore, for perfect ventilation, the proportions and position of both outlet and inlet must be considered; neither can be neglected; and if in the room on which Mr. Tobin experimented the air remained pure, it was because there was, in addition to the inflow, some means for an outflow of a sufficient quantity of air to remove impurities. In English rooms of ordinary construction the open fireplace creates the difficulty in the introduction of fresh air. It is the cause of draughts, because the chimney with a fire in the grate is a strong engine for removing the air from a room, and it draws in through every means of ingress air to supply the place of that removed. If this air comes in cold, draughts are felt, whatever be the position or manner in which the air is delivered. The hotter the fire the stronger the current up the chimney, and the greater the draught. For this reason, if a room with an open fire is to be really comfortable it should be provided with a continuous supply of fresh warmed air, and if the inlet be from 6 to 9 feet above the floor the inflow will not be felt by the occupants. The waste heat from the fire affords the most economical method of warming the fresh air. Where the principles of ventilation are carefully attended to, and where the inlets for fresh air and the outlets are duly proportioned to each other and placed in proper positions, and the fresh air adequately warmed and cooled as required, there will be no failure in ventilation. Where failure does occur it is either because of a misapplication of principles, or of a disinclination to incur the necessary expense for carrying the principles into effect.

Dr. Bradenell Carter, in the "Times" of the 17th inst., says:—I venture to think that Captain Galton is entirely mistaken in supposing that either he or anyone else in England has ever before adopted anything like Mr. Tobin's system of ventilation. The essence of that system, as I understand it, depends upon the delivery of air in vertically ascending columns, and in the utilisation of the pressure of the atmosphere for maintaining the vertical ascent of the inflow after it is delivered. In 1869 I had the pleasure of hearing Captain Galton deliver an address on the construction of hospitals before the British Medical Association, and that address, in its published form, is now before me. It enters very fully into the question of hospital ventilation, but it distinctly describes and recommends a horizontal inflow; and the vertical shafts behind the fire-places in the Herbert Hospital are figured as opening on the face of the wall, so as to deliver warmed air horizontally. I am quite sure that so acute an observer as Captain Galton, if he had once, even by accident, witnessed the effect of air delivered vertically, would immediately have recognised the great superiority of this method over all others, and would have urged its adoption wherever his influence could be brought to bear, either by tongue or pen. I must again differ from Captain Galton where he says that "the principles of ventilation are well known." I quite admit that certain principles have been laid down, by none with more force and clearness than by himself, and that these principles have been widely accepted. For the last few weeks, however, I have been in the hourly observation of facts which convince me that these accepted principles are to a great extent erroneous, or, at least, that they are conclusions which have been founded upon insufficient data. When Captain Galton writes that "if this air comes in, cold draughts are felt, whatever be the position or manner in which the air is delivered," he reminds me of the elaborate articles in which the "Edinburgh Review," some fifty years ago, showed the impossibility of railway travelling. The very able writers in that journal proved, beyond the possibility of doubt, that the revolutions of the wheels of an engine intended to be locomotive would not communicate movement to a train; and that if, by any mischance, movement of the train did occur, the passengers would all perish by suffocation from the impossibility of breathing during rapid travelling. When reputed principles will not harmonise with manifest facts, I am more disposed to reconsider the principles than to doubt the evidence of my senses. Into the female ophthalmic ward at St. George's Hospital, which contains nine beds, is warmed by a single fire-place, and lighted by two windows, four vertical tubes have been introduced. Each tube is semi-circular in section, with a radius of $2\frac{1}{2}$ inches, giving a total area of about 40 square

inches. From each tube there ascends a continuous current of air, varying in its rate of flow, but always perceptible. The currents are unbroken as high as a long taper held at arm's length can follow them. They do not spread at all until they reach the ceiling or its vicinity; and if they occasion draughts, the flies on the ceiling are the only sufferers. There is no trace of draught in any part of the ward, which is accessible by ordinary means, and no draughts are felt either by patients sitting round the fire or by those lying in bed, although the heads of some of the latter are within a foot of the openings of the tubes. The door of the ward is kept closed, and the atmosphere within is fresh and untainted at all hours of the day and night. The patients who were in the hospital when the system was introduced were, without exception, delighted with the greatly increased comfort which was afforded them. The rate of inflow of air seems to me to be governed by the demand—*e.g.*, it is perceptibly increased during visiting hours; but the general temperature is not lowered. At my visit to-day the thermometer stood at 65°, and in the male ward, which resembles the other in every respect, except that it is not yet ventilated, the temperature was only 63°. It is not the least advantage of the system that it requires the door to be closed, and each ward to be complete in itself, so that there can be no passage of hospital atmosphere from one to another. For the present, I am content with the state of the female ward; but, in anticipation of summer, I purpose to have a fifth tube inserted, and also to have window openings on Mr. Tobin's principle. At home my experience is of the same kind. There are no draughts in the ventilated rooms, but the air contained in them is always fresh and sweet, and, when gas is lighted, there is no superheating of the air above the burner. I am distinctly conscious of increased comfort and increased power of work from the improved atmosphere in which I live.

Scarcity of Water.—It has been shown, by a deputation who waited upon Mr. Selater-Booth the other day to urge the appointment of a Royal Commission to enquire into the water supply of England and Wales, that the rural water supply is everywhere getting scarcer in consequence of rivers becoming more and more contaminated with the matter thrown off by towns and villages; while, in many parts of England, there is often a scarcity of water amounting almost to a famine, "and it is no uncommon thing for women and children to wait for hours with little vessels to carry away a scanty supply for the domestic purposes of the family."

Use of Mineral Poisons by Cultivators.—Dr. Le Conte recently called the attention of the Philadelphia Academy of Science to the extensive use of Paris or Schweinfürth green for destroying insects injurious to vegetation. Paris green is a mixture of arsenite and acetate of copper, and in the result of certain empirical experiments has been recommended as destructive to the Colorado Potato beetle, and, in fact, as a universal remedy against injurious insects which appear in masses. Now arsenic and copper are poisons which act with equal energy upon plants and animals. The material, though diffused upon the leaves of the plants to be protected, which are incapable of absorbing it, is speedily carried into the soil, and if used annually it is merely a matter of time how many years will elapse before the soil is poisoned so as to prevent the growth of all vegetation. The chemical possibilities which may result in the poisoning of the vegetation raised from the soil I will leave to be developed by my colleagues. I solemnly protest against the loose manner in which, on the recommendation of persons who have observed only the effects of these poisons upon the insect pests to which their attention has been directed, a most dangerous material has been placed in the hands of large numbers of men. The manufacture of this poison has increased to a fearful extent. A friend residing in one of the great agricultural centres of the West writes that the druggists of his town order it by the ton. The ravages of the Colorado Potato beetle, which has been the chief cause of the use of Paris green, commenced in the West many years ago, and its extension at a regular rate was predicted by entomologists. The prediction has been verified almost to a year. An interesting discussion followed the reading of this paper. All the members who took part in it approved Dr. Le Conte's views as to the danger of using Paris green. Prof. Silliman had heard of several instances of loss of human life from carelessness in its use for killing cockroaches. The discussion finally took a wider range, and embraced the rise of aniline dyes for colouring jellies and confectionery. It closed with the adoption of the following resolution, on the motion of Prof. Alexander:—"That a committee be appointed to investigate and report upon the subject of the use of poisons applied to vegetables or otherwise for the destruction of deleterious insects and other animals, and also the incautious use of poisons in the ornamentation of articles of food and for decorative purposes generally, such, for instance, as the colouring of paper."

TREES AND SHRUBS.

THE STONE PINE OF ITALY.

(PINUS PINEA.)

IN the review in *THE GARDEN* (p. 233), of Mr. Gordon's new edition of his admirable work "*The Pinetum*," attention is directed to his description of *Pinus Pinea* as being somewhat vague and disjointed. Few cone-bearing trees enjoy such a world-wide reputation as the Stone Pine of Italy, and the description of it by Mr. Gordon as "a low-growing tree of 15 to 20 feet high" does it but scanty justice. In northern Europe, and especially in England, its general appearance is certainly that of a low-growing tree, its densely-clothed branches forming almost a spherical mass; but, in the sunny south it attains a height of 75 to 100 feet, losing, as it ascends, all its branches, except those towards the summit, which, in maturity, assume a mushroom form; these extend widely and laterally, and when illuminated by the setting sun become, with the smooth, lofty shaft, intensely red, whilst the dense foliage is of a rich olive tone with deep sombre shadow—a combination of colour that produces a magnificent effect. In Rome and its vicinity, those of the Villa Borghese (which are represented in the accompanying engraving), as well as those of the Villa Pamfili-Doria, and the Pine Groves of the Villa Barbarini at Albano, are well remembered; some of these now live only in memory, many hundreds having been ruthlessly destroyed during the more recent wars and sieges. A very wide-spreading but short-stemmed specimen covers the whole area of the well-known Maze, in the Alfieri Villa. The lofty, or normal type, with the umbrella-formed top, is almost peculiar to Central and Southern Italy. In Spain, the south of Europe, and England, though often attaining large dimensions, it remains more dwarf and rotund in shape. The celebrated "*Pineta*"—its chief habitat, skirts the shores of the Adriatic to a distance of 20 miles from the River Lamone, north of Ravenna, to Cervia, on the south, and is from 1 to 3 miles in breadth. No forest is fraught with more poetical and classical interest than the *Pineta*, the glories of which have been especially sung by Dante, Boccaccio, Dryden, and Byron, and it is still known as the "*Vicolo de' Poeti*." The cones of this vast forest supply the "*pignoli*" of commerce, yielding about 2,000 rubbii annually, whilst the empty cones are used extensively as fuel. The Italian cooks use these seeds in their soups and ragouts, and in the Maritzozzi buns of Rome. They are soft and rich, and have a slightly resinous flavour. The *Pinus Pinea* was highly esteemed by the Romans and mediæval Venetians as valuable timber for masts and ship-building. The finest specimen with which I am acquainted in England is in a garden at Clapham Common, and is associated with Cedars of Lebanon, Acacias, and other noble trees.

Glen Andred, Sussex.

DIFFERENT KINDS OF IVY.

No evergreen that we possess equals the Ivy in adapting itself to local surroundings, and it is remarkable that so useful a plant has never yet occupied that place in ornamental gardening which it well deserves to hold. Lately it has been brought rather prominently into notice as a plant for ornamental screens, but this is only one out of many uses to which it is adapted, both in the open air and under glass, as well as on the cottage window-sill, where it will grow, and may be formed into any shape—an object of beauty, where few plants of any other description would thrive. Of course, when I speak of Ivy growing indoors, I refer to the small-leaved varieties, whose habit of growth and formation of leaves give them a superiority over the large-foliaged kinds. One of the prettiest and most compact among the small sorts is the Palmate-leaved Ivy, the leaves of which in many places assume in autumn and winter lovely bronze and golden tints. This is the best variety for covering dead walls in villa gardens, as it scarcely ever requires thinning. Ivy, too, makes a charming evergreen fence when trained on any description of iron rails, which, when well covered, have a light and pleasing appearance, especially in winter. Niches or rustic recesses in Ivy-covered

STONE PINE TREES IN THE GARDENS OF THE VILLA BORGHESE.

walls form excellent places for vases or other kinds of flower-stands; and, if the vases or stands are set on pivots, in such a way that they could be turned round at any time in order to expose all sides to the sunlight, bulbs and other spring flowers would succeed well in them. Recesses of this description are also well adapted for statuary. At the end of a broad terrace that skirts the base of the Pentland Hills there is an Ivy-covered grotto, on each side of the entrance to which is a niche, in which stands rude stone statues of Robert the Bruce and Earl Douglas, and with no other surroundings would they have been set off to such advantage. In rustic gardening Ivy is indispensable; it can be made to assume any shape, provided attention and care are bestowed on it, so as to keep it within proper bounds. The question as to whether it creates damp or not in the walls of dwelling-houses seems to be yet undecided. The late Mr. Loudon was of opinion that it kept them dry; it, however, affords a harbour for spiders and other insects that find their way into the houses; and I may add that rats sometimes find it very convenient when they want to enter an open window. My own observations seem to prove that when a dwelling-house stands in a low situation Ivy is not a desirable plant to have upon its walls, but that when a residence stands high, and is exposed freely to the blast, it forms an excellent protection against damp. A shooting lodge, with which I am acquainted, was built of stone so porous that it sucked up moisture like a sponge; but since its walls have been covered with Ivy they are comparatively dry. Where Ivy has been established upon walls for years its rootlets become so thickly matted that rain can hardly penetrate them. Every lover of woodland scenery must agree that trees festooned with Ivy are improved in appearance. We have a variety of it here, the leaves of which are diamond-shaped, and of a beautiful bright green. It does not run upon the ground, but ascends trees, and it appears to prefer dwarf ones to such as have any great height, and so dense and thick does it grow that a Hawthorn covered with it looks at a little distance off like a fine standard Portugal Laurel. This I consider the best sort with which to cover decayed trees or stumps, for, when once established, its stems become self-supporting; and, as its leaves seem to grow brighter as winter advances, it forms a very suitable plant for the shrubbery or wild garden. The variety alluded to by "Salmoniceps" (see p. 311), though a fine kind, does not adhere to wood or stone so tenaciously as other sorts. All things considered, the palmate-leaved sort is the best I have ever met with. The leaves vary in colour, from a pale green to a beautiful bronzy hue, and, as I have already said, it requires little or no training, adhering, as it does, to walls most tenaciously. But its proper and natural place is upon the grey tower or mouldering ruin, on which it shows its beautifully tinted leaves to good advantage.

J. T.

MORE NEW PLANTS FROM JAPAN.

MR. S. B. PARSONS alludes, in the "American Garden," to the following recent introductions from Japan. A new weeping *Retinospora*, about 2½ feet high, with branches not simply drooping, but regularly weeping—in as pronounced a style as the common Weeping or the Kilmarnock Willow; its evergreen branches curved over from the top and, reaching the ground, rested upon it. With the exception of the Weeping Hemlock, there is no evergreen so pronounced in its character. A very fine *Magnolia*, which has since bloomed, proves to be of the *purpurea* family, with flowers darker and richer than *gracilis*. Another *Magnolia* is apparently dwarf, with round leaves, ferruginous on the under side. A new *Cornus*, with broad golden variegated leaves, proves very rare and beautiful. The *Daphne* *Gwenka* is already in bloom (March 10th) with blue-lilac flowers. Its earliness and hardiness will make it a great acquisition. There were 150 plants of those beautiful Japanese Maples, some of which have leaves cut like the finest lace, with colours of the richest pink, scarlet, and purple. There were some specimens of a new *Spiræa*-like plant, which are now showing leaves, and which Mr. Hogg thus describes:—"It bears immense quantities of fragrant white flowers in a sort of panicle, and somewhat resembles a *Spiræa* in general appearance. It will prove a fine addition to our hardy shrubs, from the fragrance of its flowers. There are, also, a new *Photinia*; some plants of a very curious cut-leaved Oak; the *Trochodendron aralioides variegatum*; a variegated variety of the *Planera*

Kaki; five species of *Rhus*; three new evergreen broad-leaved Laurels; the *Pinus Massoniana variegata*, very distinct and beautiful in its markings; a number of new Tree Peonies; a species of *Schizophragma*; a hardy twining *Hydrangea*, from the Japanese mountains; two new varieties of the very beautiful plant with drooping racemes of yellow flowers, known as *Hamamelis japonica*; another genus related to it, known as *Corylopsis*; two varieties of *Stuartia japonica*; a new variegated leaf *Corchorus*; two varieties of variegated *Deutzia*; three other new varieties of *Deutzia*; a new *Magnolia* with fragrant white flowers; the *Magnolia compressa*, a Japanese species resembling *M. fuscata*, only of much stronger growth; three varieties of *Raphiolepis*; a variegated leaf *Eriobotrya japonica*; a variegated *Ilex tarajo*; a variety of *Eurya*; a new Willow; a new *Pyrus*; two new *Pinus*; two new *Viburnums*; a number of sorts of dwarf *Cryptomeria*; a new *Skimmia japonica*; a variegated-leaved *Pyrus japonica*; a weeping *Cerasus*; three new Oaks and two new *Arbor-vitæ*, besides the *Cercidophyllum*, a charming shrub which we have growing freely from a previous importation.

The Redwood Supply.—Recent estimates of a quantity of timber in California show that, with due care in planting young wood, it is practically inexhaustible. In Sonoma County alone it is estimated that there are 1,000,000,000 feet of Redwood, if it were all sawn into boards. The present annual exportation amounts to 20,000,000 feet, so that there is enough to last fifty years, even if there were no new growth obtained. Considerable tracts will average 900,000 feet to the acre, and a single tree has been known to produce 50,000 feet. Humboldt is still richer. The following table shows the number of acres of Redwood, the average feet of hard timber per acre, and the aggregate feet in each district:

Districts.	Acres.	Average.	Aggregate.
Eel River Basin . . .	100,000	800,000	80,000,000,000
Van Dusen Basin . . .	15,000	600,000	9,000,000,000
Salmon Basin . . .	20,000	800,000	16,000,000,000
Elk Basin . . .	35,000	600,000	21,000,000,000
Madand Century . . .	150,000	900,000	135,000,000,000
Little River, &c. . .	250,000	100,000	25,000,000,000
Eureka, &c. . .	105,000	200,000	21,000,000,000
Total	675,000		307,000,000,000

The mills of the county now cut about 40,000,000 annually, at which rate they would exhaust the supply in 7,675 years. Sonoma and Humboldt together have not a quarter of the fine timber trees of the state, and not more than 1 per cent. of the stock on the coast west of the summit of the Sierra Nevada and Cascade Range.

The Olive in Portugal.—The Olive plays no inconsiderable part in the ordinary food of the people of Portugal; and the experience of ages has shown it to be both grateful to the palate and wholesome. The common practice is to allow the larger and more fleshy kinds to become ripe—i. e., black—when they lose a good deal of their astringent and acrid taste. These are then scalded in water considerably under boiling, into which an ounce or so of soda to the gallon is dissolved, and allowed to stand in it for three or four hours—in fact, till it is cold. They are then taken out, and well washed in cold water several times over, and finally put into a clean wooden or large earthenware vessel, and completely covered with a pretty strong brine of salt and water, and covered up from the air. Another lot, first treated as above, is put down as a pickle in moderately strong vinegar, and used as required.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

New Variegated Maple.—A very neat form of the well-known Silver-leaved Maple has been introduced to notice by Ellwanger & Barry, of the Mount Hope Nurseries, Rochester, N. Y., which promises to be a valuable acquisition. It is called Weir's Cut-leaved Maple, and is remarkable for its deeply lacinated foliage. I read the above in an American paper. Will any of the readers of THE GARDEN tell me if the plant is in cultivation.—T. S.

Rhododendron Falconeri.—A plant of this fine variety is at present in flower here, showing five trusses of its large, round, creamy-coloured flowers. The plant must be nearly twenty years old, and never bloomed until last year, when only one truss flowered. I had seeds of this variety, and the following kinds of Bhotan and Sikkim *Rhododendrons* from the late Mr. Hugh Low, of the Clapton Nursery:—*Argenteum* *Campbelli*, *Campylocarpum*, *Jenkinsii*, *Dalhousianum*, *Aucklandii*, and a small flowering kind with tubular red flowers. This was in 1854, and they have all flowered now, *argenteum*, *Campbelli*, and *Falconeri* being the shyest in flowering. With age they make fine plants for a large greenhouse or cool conservatory, and if planted out in the borders, together with arborea, they would be the handsomest greenhouse flowering trees in cultivation.—WILLIAM TILLERY, *Welbeck*.

The Fever Gum Tree in California.—General Nagle of San José is said to have "the finest avenue of *Eucalyptus* in California." The lines are more than 1,000 feet long; the trees, planted six or seven years ago, are 60 to 70 feet high, and their trunks "large at the base as barrels of flour."

GARDENING FOR THE WEEK.

Hardy Fruit.

FRUIT prospects this year are, on the whole, most cheering. Apricots have set an abundant crop, Peaches are one mass of pink blossom, Pears on south and west walls are sheets of white bloom, and Cherries and Plums are the same; but we are not yet out of the wood, so to speak, as one night's frost, such as we sometimes get at this season, might ruin our hopes. Therefore, the anxiety felt for the safety of the crop should awaken us to action in devising ways and means to protect the blossoms on the first indications of frost; for, though the season is backward and so far favourable, still, it will not do to trust too much to our fickle climate. Where proper coverings for walls exist these are generally let down at night and drawn up in the morning, but in the event of sharp frosts they should remain down for some time after the sun is up; and if very bright they are better down altogether, as more harm is sometimes caused by the fierce rays of the sun than even frost itself. The great show of bloom on many trees this season will make it absolutely necessary to thin some of it. At this busy season but little time is at command for such work, but an effort should be made to go over some of the choicer kinds of Peaches and Pears, and take off the weakest blossoms from some of the largest spurs; those left will set all the better and furnish finer fruit than would otherwise be the case. Apricots often set their fruit in clusters, and these should now be thinned out, taking off the smallest and badly-placed, and pinching back the new growths to two joints. Peaches and Nectarines should also now be disbudded, an operation frequently recommended to be done by degrees, *i.e.*, by going over the trees several times, and taking a few shoots off each time at intervals of a few days. Where the trees are left too long before disbudding takes place, I can understand such a proceeding being necessary to prevent a check being given to the trees, but experience teaches me that if done early it may be done finally. As soon as the fruit is set it will be advisable to thoroughly syringe or wash the trees with the garden engine, in order to cleanse them from fallen blossoms, and, if aphides appear, dust with Pooley's tobacco-powder or syringe with tobacco-water; of the two remedies, the former is the most effectual and easiest of application. Currant bushes are frequently, even before the foliage has fully expanded, attacked with the blue aphides, for the destruction of which I have found nothing better than frequent washings with clear water. Gooseberries infested with the caterpillar can only be effectually cleansed of it by means of hand picking the moment it is perceived. Grafting will have been completed ere this, but it will still be desirable to look over all trees thus operated on, in order to see that the clay is not cracked by drought, or washed off by rain. As soon as the grafts have taken, rub off any shoots produced by the stock. Should the weather continue dry, late-planted trees will require watering; after which, if not previously done, cover the roots with half-rotted manure, and see that all are securely staked and tied, to prevent wind-waving. New roots are destroyed as soon as they are produced where rocking to and fro is permitted to take place to any great extent. Well trench and manure a piece of ground for the Strawberry plants now being forced, which, as soon as hardened off, should be planted out. From these a crop of fruit may be gathered in autumn. The best kind for this purpose is Vicomtesse Héricant de Thury. From this kind, planted in the end of April last year, I gathered many dishes of finely-flavoured fruit all through the month of October; and the only attention they had after being planted was an occasional watering, the flowers also being sometimes picked off till the plants had fairly started into growth.—W. WILDSMITH, *Heckfield*.

Indoor Fruit Department.

Vines.—All young Vines should now be growing freely, and those rooted in small pots must be shifted into larger ones before their roots become coiled and matted, for when this is the case the roots do not penetrate the fresh soil so quickly and freely as is desirable. The time to re-pot should depend more on the quantity of the roots than the size of top growth, as a large number of roots is produced from shoots not over 12 inches in length, and Vines of this description are often as fit for shifting as others with a growth three times longer. All kinds should be shifted into their fruiting pots. Many pots are still used that are considerably over a foot wide for growing fruiting canes, but a great deal of labour may be saved and the same results obtained by never exceeding this measurement. Those intended for planting canes should be put into 6 and 8-inch pots; for, although as good canes may be obtained in a 4-inch pot as either of these sizes, the roots in that case are not in such good order for planting out at the end of the season. After potting, the ball should be moistened with a fine rose watering-pot, and they should be subjected to a temperature of 65° at night and to 10° or 15° more

during the day for a few weeks. Shading during strong sunshine prevents the leaves from flagging, and is not trying to them until fresh roots enables their full exposure. A moist atmosphere is also beneficial to them. Those propagated in boxes, or beds of soil and turf, should be ready for root pruning by this time, and a large, sharp knife should be run between each row, going to the bottom at each cut, so as to divide the roots; water as soon as this operation is performed, and keep a little close for a few days. A week hence cut in the same manner the other way, when each Vine will be left with a square of soil for itself. So soon as the small rootlets have begun to show at the part where they have been cut they should be carefully lifted and potted in the same way, and be treated in a similar manner to those raised in pots. Widen the space between those growing on turves, for the roots of one should never be permitted to enter the square of another. Any strong roots which appear at the edge of the turf should be pinched back, when a quantity of small roots will be formed, which are of far more service than a few long ones.

Pines.—A temperature of 65° is now a suitable heat for the generality of Pines at night. Unless where the fruit is wanted immediately, much finer specimens will be produced in this temperature than in one 10° higher. Air must be given earlier in the morning than hitherto. Admit it gradually after the thermometer indicates 75°, and increase it, as required, until 85° is reached by sun heat. It is a bad plan to run up to this degree before giving air, and suddenly, by opening the ventilators, to reduce it. Close before the influence of the sun is off the houses; and the temperature at this time may be allowed to rise to 90°. On mornings which give promise of a good day, damp the fires by putting in the dampers; close the ashpit doors, put wet ashes on the fire, and start again in the evening in time to keep up the above night temperature until the following morning.—J. MUIR.

Flower Garden and Pleasure Ground.

Continue gradually to harden off bedding plants of all sorts by transferring them from the close warm atmosphere of the propagation house to cold pits and frames, and afterwards to sheltered situations in the open air, where they can have the protection of mats, or other materials, when danger from frost is apprehended. Annuals which may have been sown some weeks since in heat, will now be fit to prick out into pans, boxes, or frames. Keep them for some time somewhat close, until they become again established, when they may become gradually hardened to full exposure to the open air, when advantage should be taken of the first opportunity after a good fall of rain to plant them out where they are intended to flower. Seeds may also be sown now, upon a shady border in the open air, of such plants as the Sweet William, Wallflowers, Anemones, Pansies, Polyanthuses, and Alpine Auriculas; or such seeds may be sown in pans or pots, under glass, and planted out when large enough to be handled. Keep beds of Carnations, Ranunculuses, or Tulips, free from weeds and decaying leaves, and carefully support the flower-stems, &c., by stakes, whenever this may be found necessary. Patches, or beds, of the various kinds of Violets should now be broken up, and strong well-rooted runners should be selected; these should be pricked out into light sandy soil on a shaded border, and should be well supplied with water until they are fairly established. It is always advisable to form fresh beds of these plants every year, as young plants are always found to bloom more profusely than old ones, and they also furnish much finer flowers. Amongst the finest of these sweetly-scented flowers is the Neapolitan variety, although it seldom succeeds well in the open air in this country, but requires the assistance and protection of a frame; where, to induce it to produce blooms early in the spring, it should be planted near the glass, and the temperature of the frame should be slightly increased by means of fermenting materials placed around it. The double and single Russian kinds are also very useful and quite hardy, as are also the varieties known as the King and the Queen of Violets. The former is a fine, large, double, dark blue sort, and the latter, with flowers equally large and double, is in colour nearly pure white; while the Czar is a fine, hardy, robust sort, producing a profusion of single blooms at an earlier period than any of the other sorts, and is, perhaps, slightly less sweet-scented than some of them. There are, also, in addition to the sorts already mentioned, several other valuable varieties, including some novelties, which are highly recommended. The present is also a suitable time to cut and regulate the margins or Grass verges of walks and clumps, &c. This operation should be carefully performed with the edging iron, with the assistance of garden line and pegs, and this should be done every season, or at least once during every two years, although a deep raw edging to a walk is exceedingly objectionable, yet the level of the marginal turf should be somewhat higher than the level of the gravel at the sides of the walk, so as to admit of the Grass shears being applied, and these should be used on every occasion when the Grass is mowed, so as to

distinctly define the margins, and to prevent the Grass from growing into the gravel. There is nothing that renders gardens and grounds more enjoyable, than thoroughly good gravel walks, while, on the other hand, being compelled to walk upon rough, loose, or unset gravel, is anything but pleasant. Even the colour of the gravel forming the walks has much to do in giving character to the aspect of the surroundings of the mansion or residence, or in the production of a cheerful and pleasing effect or otherwise. It is also of the greatest importance that walks should be rendered as dry as possible by thorough drainage. They also ought to be smooth, hard, and solid; river gravel is consequently seldom well adapted to the purpose of walk making, being generally deficient in binding properties. Perhaps the best gravel is to be obtained from pits, which usually contains an admixture of loam, that gives to it the necessary consistency. But, of whatever nature the gravel may be, in order to render walks firm and solid, it is always necessary to roll them well when in a moderately wet condition, and this operation ought to be frequently repeated, in order to keep them in good condition. About this time it is also sometimes found advisable to destroy weeds and Moss by the application of a good dressing of salt, which gives also a clean appearance to the gravel. There is, however, one condition necessary to the success of the operation—that is, a few bright sunshiny days to follow, for, if rain should fall very closely upon the application of the salt, little advantage will be derived from it. It is also necessary to take great care that the salt does not come within a distance of at least 6 inches of Box, Grass, or other edgings, otherwise they will be destroyed.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Roses.

Allow me to inform Mr. Fish, in reply to his remarks (p. 319) that flowers of *Auguste Mié* and of *Coupe d'Hébé*, placed in a stand, have been shown by me to good judges, and have been taken for one and the same variety. *Auguste Mié* resembles *Coupe d'Hébé* not only in colour, but also in wood and foliage. *Madame Rivale* is a much lighter Rose, but in shape, and even in the character of the wood, is like *Auguste Mié*; and there is no doubt that *Madame Rivale* is often sent out as that variety. These Roses excel in shape many of the older varieties. Roses vary according to soil and treatment. Blooms for show purposes require to be large, full, and good in form—points that are all taken into account by good judges of Roses. As regards new Roses, scent should be made a matter of more importance than hitherto. A great many new varieties are almost destitute of fragrance, a property possessed in such a marked degree by the old Cabbage and common Roses. Our new Roses have beautiful shapes and colours but, as regards scent, little can be said in their favour. Such kinds as *Baronne Prevost* and *Géant des Batailles*, when fully open, are incomparable, as respects form, with such finely-shaped Roses as *Paul Neron*, *Countess of Oxford*, *Victor Verdier*, *Pierre Notting*, *Xavier Olibo*, and others of that class; therefore, when we plant Roses for show purposes, form is the chief point to keep in view; but many of our best show varieties are also equally good for garden decoration; but, in the latter case, we ought also to have fragrance. All, therefore, who intend purchasing new varieties for planting next autumn, will do well to visit our great Rose nurseries during the summer, and make a note of such kinds as possess the best qualities in the most marked degree. Fine foliage, such as that belonging to *Victor Verdier*, *Centifolia rosea*, *Boule de Neige*, *President Thiers*, *Beauty of Waltham*, and many others should also be secured. Pot Roses will now be in perfection, and it is well to select from among the varieties shown such as are of good habit and colour.—H. G.

Kitchen Garden.

There is yet time, if desirable, to make new plantations of Globe Artichokes for autumn bearing. Our usual way is to take up a row, divide the roots, and plant elsewhere, using good large pieces in preference to offsets, as the latter rarely produce much the first season. Four feet apart each way is a good distance, or, where ground is scarce, 3 feet from plant to plant may do. Early blanched Celery is often in demand for stewing, flavouring, &c., before it can be obtained in the usual way in the open ground, and, where the necessary facilities exist, it may be forced easily. Open a trench, the width of any available frame, 2 feet deep, and near the water supply. When this has been trodden down, fill in to a depth of 15 or 18 inches with any material that will furnish a mild bottom-heat for a few weeks, so as to give the plants a start. Spent hotbeds turned over and watered will usually do this, or, if necessary, a small proportion of the short Grass from the pleasure ground may be well mixed with it. This, however, must be used sparingly, as it throws off a violent heat. Spread over this a layer of rotten dung, and place on the surface 4 inches of rich soil. Plant out in rows, 8 inches apart, and 6 inches from each other in the rows, the best and strongest plants obtainable.

Success will, in a great measure, depend upon the plants having been grown unchecked from the seed. Very early sown Celery, unless carefully managed, often proves a failure. Mushroom-beds should now be made in the open air, or in some open north shed, as in a Mushroom-house of the ordinary kind, it is, in hot weather, next to impossible to obtain them free from maggots. There will be no difficulty in keeping up the requisite temperature in the open air beds from this time, but the litter should sometimes be turned over and shaken up; for, if the layer next the bed gets damp, the spawn, when working, will sometimes run into the litter, and thus partially exhaust itself. Where it has not yet been accomplished, this is a good season for re-arranging the herb beds. Sage, Rosemary, Rue, Hyssop, Lavender, &c., usually raised from slips or cuttings, will strike better now than at any other time. Most of those I have named may also be raised from seeds sown now. The common Thyme should also be sown now, and new beds made from the seedlings sown last year. Lemon Thyme, Pennyroyal, Balm, and Chamomile, should be divided and re-planted annually; the latter especially is apt to degenerate if grown long on one plot of ground. I have already referred to Mint and Tarragon in former Calendars. See that a liberal supply of Parsley is provided, and any sown in boxes may soon be pricked out. Transplanting has a tendency, by increasing the curliness of this plant's foliage, to make it more ornamental in appearance. As soon as possible the hoe should be employed amongst Onions and other crops now coming up. Stirring the soil frequently helps the growth amazingly, besides keeping down weeds. North borders will soon become useful for sowing Radishes, planting Lettuces, Cauliflowers, &c. Where it can be done, the old Mushroom-beds should be saved for mulching salading by and bye; broken up fine with a fork, and placed amongst Radishes and Lettuces, it not only saves a vast amount of labour in watering, but adds to the quality of the produce. Rampion may be sown on finely pulverised ground. If sown in drills they must be very shallow, as the seeds are very fine. I generally grow it on 4 feet beds; rake the surface finely, sow the seeds thinly, cover with a very shallow layer of fine sifted soil, flatten it down with the back of the spade, and finally thin out to 6 inches apart. The flowers of this plant are exceedingly pretty, and it would make a very handsome border biennial.—E. HOBDAY.

SETTING BOILERS ABOVE THE PIPES.

So far as this discussion has gone, the weight of evidence seems in favour of retaining the deep stokehole, or, at least, placing the boiler well under its work. With facts pointing to a different conclusion, however, daily before my eyes, I find it difficult to acquiesce in the verdict. During the last twenty-five years, I have worked a good many different forms of boilers set more or less deeply in the ground; but I have never been better satisfied than I am now with our present arrangement. It will probably be in the recollection of many of your readers that a good many years ago, what is now termed the "one-boiler system" was in its infancy. It was a common plan in attaching two or three houses to one boiler to take the flow from the boiler to a small iron cistern or tank, in which all the valves were placed. This cistern, or valve-box, was placed above the boiler, and was, in fact, the highest point the water reached, and from which it was distributed in a gradual descent—varied, of course, according to the exigencies of each case—till the boiler was again reached. I worked two apparatuses on this principle twelve years; and for rapid circulation and perfect control over them, I have never met with anything superior to them since. Doubtless, the more simply the pipes are arranged, the less friction there will be, and, consequently, less waste of power; but when half a turn of a valve will send the water rapidly in any required direction, there cannot, I think, be much loss of force. I have always been in the habit of bestowing upon the stokehole, and its belongings, as much attention as upon any matter that comes under my care; and I know of nothing that pays better for personal supervision. I cannot understand how anyone can call a good example of a vertical tubular boiler a wasteful one. If properly set and well managed, I consider it at least equal to any other form, both for economy and efficiency. I well remember the severe winter of 1860-61. How earnestly I wished the four boilers then under my charge had all been vertical tubular. There are, however, two things essential to economy in any boiler, but more especially so in the case of a vertical tubular, viz.,—plenty of boiler power, in proportion to the work to be done, and intelligent stoking. The main secret of economical management lies in keeping the boiler clean, and in the proper regulation of the ashpit door, and the damper in the chimney. Steady, but comparatively slow combustion, is the right principle to adopt if we wish to derive the maximum amount of heat from the fuel and usefully employ it; and, to

the neglect of this, I attribute the various complaints we sometimes hear of vertical tubular boilers being wasteful. With reference to making a stokehole watertight, I imagine, from the easy way in which some of your correspondents speak of the matter, that they hardly appreciate the difficulties that have, in some places, to be encountered; to make a stokehole, 6 or 8 feet deep, watertight is in this district a very costly affair. Some time ago a gentleman, who had built a greenhouse in the Fens, adopted the expedient of placing his boiler in an iron tank to escape the annoyance of water breaking in, although the stokehole was comparatively shallow; had it been clear to him, then, that the water would have circulated with the boiler placed on the surface that heavy expense might have been avoided. In making a stokehole watertight with cement, it should always be borne in mind that a large heavy boiler, with its mass of supporting brickwork, presses heavily on the foundation; and in all the cases of failure I have examined, I have found the water trickling down from some inaccessible spot at the back of the boiler; the conclusion, therefore, to which I have come is, that it was caused either by a slight settlement when the boiler was placed in position, or by expansion from the fire.

E. HOBDAV.

The following facts, which are the result of long practical experience in heating by means of hot water, may not be unacceptable to your readers, especially as we venture to think they may not be without effect in reconciling, or partially explaining, the conflicting views lately put forward concerning this mode of warming by some of your correspondents. An early form of our upright tubular boiler was erected by us about the year 1859, for the late Mrs. Foster, at The Holme, Regent's Park, and was in constant operation, and performed its functions with efficiency, until replaced in the early part of last year by one of our duplex ones. The top of the boiler removed, as well as of that recently put in, stands about 4 feet 9 inches above the pipes. Here, then, is an instance in which the principle under discussion, after a trial of fifteen years, must be admitted to have proved successful. Encouraged by the satisfactory results of our first efforts, confirmed as they were by previous experiments, we confidently adopted the principle, and recommended its application wherever circumstances were such as to render it advisable. From that time to the present the "dip" principle has been constantly employed by us, and upon a scale so extensive that fully one-fifth of the apparatuses constructed by us, are upon that system. Among some of the later examples of its application are the boilers of Messrs. Wood & Ingram at Huntingdon, and at Ramsay Abbey; but we can refer to others still more recent, in which the apparatus has ranged in size from the largest to the smallest, and in which the test is much more rigorous. We have recently, for instance, fitted up a very small apparatus at Swanage, in which the bottom of the boiler is nearly level with the pipes; and this has proved perfectly successful, as it can be worked at no extra cost of fuel, and the heat admits of adjustment to the greatest nicety. At Bradford, again, there is an apparatus which we believe to be one of the largest, if not the largest, in the country, and which has just been erected by us. The building in which it is placed is a factory, with half the roof of glass, standing upon an area of 1½ acre. The quantity of piping employed is about 1½ mile, and during the severe winter through which we have just passed the temperature was maintained at 56°. The top of the boiler, which is unusually large, is at least 7 feet above the pipes, but the circulation nevertheless, throughout the entire apparatus, is uniform. Thus far we have adverted to the bright side of the picture; but it has also a dark one, in the shape of the numerous failures which have certainly attended the attempts to put this system of heating in operation. These failures, however, ought not to be received as facts discrediting the principle. In a word, the arrangement of an apparatus suited to the sunken boiler principle, is not equally applicable to the dip principle. With regard to cost, we may add that this system can be worked, in the form of small apparatuses, at no extra cost of fuel; and in that of large ones the extra cost is too small to be appreciable. In some cases, indeed, there is a positive saving. Allow us to observe, in conclusion, that so far from this system degenerating it has assumed a considerable development; for, instead of being restricted to a dip in the flow, we are now enabled, as the result of some experiments which we made so far back as 26th March, 1874, to heat 2,000 feet of 4-inch piping, by water super-heated in one of our upright tubular boilers, the flow of which came off at the bottom, instead of the top. Here, then, is what we venture to deem a really practical step towards the long-talked-of abolition of stokeholes. J. WEEKS & Co.

Double Cinerarias.—I know a nurseryman, who took great interest in these plants, and who tried to perpetuate his finest double kinds from cuttings. He now, however, finds most of them to be single and worthless.—W.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 21st.

At this exhibition Messrs. Veitch & Sons showed a select and well-arranged group of new and rare Orchids and foliage plants, as did also Messrs. B. S. Williams and Mr. W. Bull. Mr. J. Walker, of Thame, Oxon, staged three splendid stands of *Maréchal Niel* Rose, which, for freshness and soft beauty of colouring, we have never seen surpassed this season. Messrs. H. Lane & Sons furnished a well-flowered group of Hardy *Rhododendrons*; and Mr. R. Parker, of Tooting, and Mr. Dean, of Ealing, had good collections of hardy spring flowers.

Orchids.—Amongst those shown by Messrs. Veitch were good plants of *Phalænopsis Luddemanniana amethystina* and of *P. Luddemanniana ochracea*; also, a fine specimen of *Saccolabium ampullaceum*, bearing nine good spikes, a perfect rosy-flowered little gem, growing on the summit of an open teak wood cylinder, as shown in the accompanying illustration, sketched when the plant was exhibited last year. From the same firm also came a plant of *Cypripedium Sedenii*, one of the brightest and most free-flowering of *Lady's-slippers*; a plant of the distinct and beautiful *Oncidium concolor*, bearing a gracefully arched spike of ten flowers; three or four plants of the ever welcome *Odontoglossum gloriosum*, *O. Andersonianum*, *O. Pescatorei*, *O. triumphans*, and a new and distinct species named *O. prænitens*, the last bearing two spikes, on which there were nine flowers. The sepals and petals are 1½ inches in length, of a clear yellowish-green tint, blotched with deep shiny brown. The wedge-shaped lip is of the same colour, and the colouring and crest of the purest

Saccolabium ampullaceum.

white. A fine specimen of *Cœlogyne cristata* came from the gardens at Trentham; it was growing in a basket, and was fully a yard in diameter, bearing over sixty spikes of snowy flowers, of which many of the spikes bore seven each. In the class of six Orchids, Mr. B. S. Williams staged good plants of *Camarotis purpurea*, a well-known Orchid, well worth a place in every humid plant stove; *Odontoglossum Phalænopsis*, with four large and richly-coloured flowers; *Masdevallia Lindenii*, with eleven flowers of the richest silvery-lilac; a fine specimen of *Cypripedium villosum*, bearing fourteen or fifteen rich brown shiny flowers; a vigorous plant of *Odontoglossum luteo-purpureum*, with two stout spikes, bearing respectively twelve and thirteen flowers; a small plant of the snowy white-flowered variety of *Odontoglossum Roetzlii*; and a vigorous specimen of the purple-lipped *Warscewiczella discolor*. Mr. W. Bull exhibited an *Anguloa*, named *Turnerii*, bearing four blush-white flowers, the petals of which were delicately mottled with rose inside, the lower sepals, being connivent and cupped at the base. In general appearance, this plant bore a marked resemblance to *A. uniflora* of some gardens. Mr. T. W. Bond, gardener to G. A. Smith, Esq., The Beeches, Weybridge, sent a well-bloomed small plant of *Oncidium altissimum*, and a fine specimen of *O. pictum*, the flower-spikes of which were trained on a large globe-shaped trellis.

Rhododendrons.—In Messrs. Lane's collection of these, the only one exhibited, we noticed, amongst others—*Nero*, a well-known kind, with rich purplish dark-spotted flowers, borne in dense clusters; *Limbatus*, a crimson-edged variety, shading to nearly white in the centre; *Blandzanum*, still one of the brightest of crimsons; *Queen of the West*, lilac-purple, with white anthers, and bright bronze-green foliage; *Fastuosum*, still one of the best double-flowered sorts; *Impératrice*, a variety with glowing-crimson flowers; and *Auguste Van Geert*, with large pale-crimson flowers, borne in immense trusses.

Roses.—Mr. H. Bennett, of Stapleford, furnished a dozen fresh little grafted plants of Captain Christy, a Hybrid Perpetual, with fine full flowers of a delicate rose colour, and of good substance. Mr. Bennett also staged two fine stands of a new Hybrid Seedling, *Duchess of Edinburgh*, a fine full, delicate rosy flower belonging to the *La France* group, and deliciously fragrant. Mr. J. Walker, nurseryman, Thame, sent three splendid stands of *Maréchal Niel*, each stand containing thirty-six large and perfect flowers of this fine yellow Rose. A stand of *Mlle. Marie Conitét*, furnished by Mr. H. Bennett, was much admired. Its smooth petals are of a delicate soft rose, rather densely imbricated, which gives a compact and substantial appearance to the flower. Mr. W. Paul, Waltham Cross, showed two new Roses in pots—viz., *Villaret de Joyeuse*, a Hybrid Perpetual kind, with full globular rosy-crimson flowers; and *Amelie Hoste*, a nearly spineless Hybrid Perpetual Rose, which bears full globular flowers of a delicate rosy-lilac or flesh tint.

Hardy Spring Flowers.—Of these, Mr. Parker exhibited a fine collection, in which were the white-flowered *Ranunculus amplexicaulis*,

with glaucous leaves, and a habit exactly like that of the silvery everlasting *Rhodanthe Manglesii*; *Dielytra spectabilis*, a yard high, and nearly an inch in diameter, profusely covered with flowers, and a small plant of its white-flowered variety. There were also fine pots of *Muscari racemosum pallidum*, a delicate blue Grape Hyacinth; *Triteleia uniflora*, and its bluish-lilac variety, and *Orobis cyaneus*, with bluish-purple Pea-shaped flowers. Of *Primulas*, the collection contained pots of the orange-flowered Golden Plover, and the rich velvety-crimson yellow-eyed kind called Early Admirable; also examples of the golden-yellow *Doronicum austriacum*, and *D. cordifolium*, the delicate cerulean blue *Scilla italica*, and the thick-leaved rosy-flowered *Saxifraga media*. Mr. R. Dean, of Ealing, had also a beautiful collection of spring flowers, including fine pots of white, crimson, and golden variegated Daisies, the lovely blue *Myosotis dissitiflora*, *Lithospermum prostratum*, with rich blue white-eyed flowers; lilac, white, and rosy-crimson forms of *Primula cortusoides*, *Viola Royal Blue*, the deep lilac-flowered *Aubrietia purpurea*, and *Iris nudicaulis*, are of the earliest and best of the purple-flowered bearded section. The same exhibitor had also a choice collection of double and single-flowered *Primulas* and *Polyanthuses*; among the double forms were crimsons, whites, lilacs, yellows, and maroons, and the collection also contained the white bedding *Polyanthus* named The Bride, and the Primrose-coloured kind called Viceroy. Alpine Auriculas came from Messrs. Dobson & Sons, Woodlands Nursery, Isleworth. A collection of the beautiful old-fashioned gold-laced *Polyanthus* came from Mr. E. Eckford, Coleshill House, Highworth. An interesting collection of *Narcissi* came from Mr. P. Barr, of Tooting. Among the finest of the varieties were Empress, a kind with white segments and a golden-yellow cup; Emperor, with sulphur perianth and golden cup; and several effective double-flowered forms of *N. incomparabilis*. Among the smaller varieties were *N. juncifolius*, *N. gracilis* var. *tenuior*, and *N. Mackaii*, *N. bicolor*, and the creamy-white *N. moschatus*, all distinct and effective, as is also the great golden *Daffodil N. maximus*.

Miscellaneous Plants.—Mr. Bull exhibited a small group of new and rare plants, among which were vigorous specimens of the vase-shaped, mottled-leaved *Tillandsia musiacae*, one of which bore a small spike of rich orange flowers, and *Dracena elegantissima*, a kind, graceful in habit, and having the bronzy-purplish-green slender recurved foliage distinctly margined with crimson. Mr. F. Kinghorn, Sheen Nursery, Richmond, sent a plant of *Fuchsia procumbens*, first introduced to this country forty years ago, but lost, and only recently re-introduced. It is, perhaps, the most elegantly habited species in the genus; the fresh greenness of its pendent branches drooping in dense masses over the sides of the pot, reminds one of *Sibthorpia europaea*; while over the whole are diffused yellow-tubed purple-petalled, blue-anthered, erect flowers, which give the plant at once an attractive and, at the same time, novel appearance. It is a native of New Zealand, is perfectly hardy on sheltered rock-work, and, as a basket-plant for the greenhouse or conservatory, it is well worth attention. A good figure of this plant, from the pencil of the late Mr. J. T. Moggridge, will be found at t. 6,139 of the "Botanical Magazine." Messrs. E. G. Henderson sent a collection of double and single flowered *Cinerarias*, one or two of the double-flowered forms being certainly very effective, and well worth reproducing from offsets, if not from seed. Messrs. Dobson, of Isleworth, furnished a collection of well-bloomed, brightly-coloured *Cinerarias*, a sharp-pointed variety of the scarlet-spathed *Anthurium Scherzerianum* came from W. Arbuthnot, Esq., of Plawhatch, Sussex. Mr. B. S. Williams sent three small plants of the new hybrid *Franciscea magnifica*, a kind having fresh green oblong foliage and purple flowers, fully 3 inches in diameter. Mr. B. S. Williams also had a fine group of miscellaneous decorative plants, among which were the bronze-leaved *Dracena Shepherdii*, *Veitchia Canterburyana*, an elegantly-habited Palm, with fresh deep green drooping leaflets; *Toxicophlæa spectabilis*, with deep green shiny foliage, and axillary clusters of sweet-smelling snowy-white flowers. In the same group was likewise a young plant of *Plectocomia Andersonii*, a distinct and irregularly pinnate-leaved Palm, having long glaucous or silvery spinose petioles, and deep glossy green leaflets. Fine groups of decorative plants came from the Society's garden at Chiswick, including some well-grown examples of *Polyanthus Narcissus*, showy Alpine Auriculas, half-a-dozen fine pots of forced Solomon's Seal, some good Callas or Trumpet Lilies, and excellent pots of the rosy-flowered *Dielytra (Dicentra) spectabilis*.

Fruit and Vegetables.—Alicante Grapes, well-preserved, and in all respects in excellent condition, came from Mr. Redout, who had kept them in water since February last. Two good clusters of Black Hamburgh came from Mr. Bones, gardener to D. McIntosh, Esq., Romford. These were of the present season's growth; each cluster weighed nearly a pound, and was well coloured. Mr. Bones also had a dozen fine Tomatoes, of the Earley's Defiance variety. A brace of Tender and True Cucumbers, 2 feet long, came from Mr. J. Lane, gardener to Major-Gen. Fytche, Tyrgo Park, Romford, and to these the first prize was awarded. It is a fresh glossy-green coated variety, and one of the best in cultivation, either for table or for exhibition. Mr. W. Rapley, gardener to R. Hudson, Esq., Clapham Common, had a good brace of Marquis of Lorne, in excellent condition. Mr. T. W. Bond, gardener to G. A. Smith, Esq., The Beeches, Weybridge, sent two pot Vines, each bearing six bunches of ripe fruit, the variety being Foster's Seedling. Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, sent six fine dishes of Apples, consisting of Royal Russet, Spanish Pippin (a plump golden-yellow fruit in excellent preservation), Dumelow's Seedling, Norfolk Paradise (a highly-coloured fruit of large size), and Alfreton, (a well-known culinary variety).

The same exhibitor also sent two dishes of Uvedale's St. Germain's and Beurré Rance Pears. Messrs. J. and C. Lee, Hammersmith, furnished plump specimens of Bess Pool, a well-known dessert or kitchen Apple, of excellent quality, especially when grown on deep rich soils. W. Terry, Esq., Peterboro' House, Fulham, sent two good clusters of Vanilla pods, ripened in a Pine stove. Mr. John Munro, Potter's Bar, exhibited fresh green fruit of his seedling Cucumber, Duke of Edinburgh, also a fine basket of Keen's Seedling Strawberry, from plants raised from offsets, with incipient rootlets attached to them. The same exhibitor likewise furnished three dishes of early-forced Grapes, consisting of Foster's Seedling, Buckland Sweetwater, and Madresfield Court.

First-class Certificates were awarded to the following new or rare plants:

Dracena hybrida (Veitch).—A robust and distinct-habited seedling, raised at the Royal Exotic Nursery, having broad lanceolate foliage of a bronze-green tint, margined with bright rosy-crimson, and streaked with creamy-yellow and bright rose. The young leaves on the plant exhibited were bright rose underneath, and delicate rose blended with cream colour above. It promises to be one of the most distinct and valuable of all the new varieties.

Daisy (Quilled) White Globe (Dean).—A robust and compact habited variety, bearing pure white, semi-hemispherical flowers, 1½ inches in diameter. It is a most profuse bloomer, the plant exhibited having on it thirty flowers and partly opened buds.

Rose Captain Christy (H. Bennet).—A first-class French Rose, having large full flowers of a delicate rose or rosy-lilac tint, the centre being of a deeper glowing rosy-hue, with a dash of salmon. The foliage is deep green, and of good substance. The wood is nearly spineless, and the flower has a very delicate Tea Rose-like odour.

NOTES AND QUESTIONS—VARIOUS.

Shading Pines.—Your correspondent, Mr. Muir, is perfectly right respecting the use of shading for Pine-apples, and particularly during the early spring months.—R. G. B.

Macadamia ternifolia.—This plant, enquired about by "K" (see p. 314), I have tried out of doors in the south of Ireland, and proved it to be tender. It is the plant which produces the fruit known in commerce as the Guayaquil nut.—W. E. GUMBLETON.

Dog's-tooth Violets.—In answer to "H. A." (see p. 320), I would suggest that his soil is too sandy for these plants; mine grow and flower in perfection in a strongish loam.—J. G. N. [Another correspondent adds that they are in too dry a position, and that if "H. A." does not remove them they may in time cease to treat him with even a sight of their leaves.]

American Dog's-tooth Violet (Erythronium americanum).—Can any of your readers tell me how to manage this beautiful plant so as to induce it to bloom? With me it runs about to considerable distances from its original position, and but rarely forms bulbs sufficiently strong to flower, though when once a bulb arrives at flowering size it generally continues to bloom year after year; I am, however, sorry to say that these cases are rare.—J. G. N.

Fruit Prospects in Worcestershire.—Peaches, Nectarines, and Apricots, which have bloomed vigorously, are setting freely, and, now that the season is so far advanced, people are looking forward to abundant crops. Owing to the long continuance of north-easterly winds and remarkable absence of sunshine, the opening of the bloom buds has been quite three weeks later this season than last year.—GEO. WESTLAND.

Rollisson's Telegraph Cucumber.—I can endorse all that Mr. Gilbert and Mr. Garland say of this excellent Cucumber. It is peculiarly a market-gardener's variety; there are here large growers of Cucumbers for the Nottingham market, and, though they have tried all the best varieties, Rollisson's Telegraph is the only one used. Care is needed in buying, otherwise you often get a Cucumber which is not Rollisson's.—N. H. P.

Rhododendron Countess of Haddington.—A noble specimen of this beautiful *Rhododendron* is now in flower in the conservatory at Furze Down, Tooting Common. It is bearing upwards of a hundred trusses of pale rosy-white flowers, each averaging from three to five flowers on a truss. Mr. Laing informed me that it had been even much finer than it now is, he having cut many flowers from it.—A. OUTRAM.

Explosion of Gas under Boilers.—If the stoker alluded to in "N.H.P.'s" note (see p. 336) were to force the greater part of the fire to the back of the furnace, and be careful not to cover it with the fresh fuel, a little space being left between the fuel and the boiler for the admission of air, the ashpit door being left 2 inches open, and the damper out about 3 inches, there would be no danger of explosions, as the fire left uncovered at the back consumes all gases that pass over it.—W. W. EAGLEBURST.

Thuopsis dolabrata.—This is one of the most beautiful of Coniferous plants, the rich massive foliage of which is, I think, unequalled by any other variety. A plant here measures upwards of 10 feet in height, and as much in width. It is symmetrical, branched close to the ground, of good habit, and perfectly hardy, but the laterals have a tendency to form leaders, which may easily be prevented by shortening to an outward growing shoot. No collection, however small, should be without this variety.—JOHN GARLAND, Killerton, Exeter.

Scillas from Seed.—*Scilla sibirica* is a general favourite, and *S. bifolia alba* flowering at the same time makes a pleasing companion to it. But to see the former in all its loveliness it should be planted in a thick line or as an edging, if only a yard long, and in a half shady position. With a little patience this may easily be done and at no expense. The bulbs are now seeding, and when the seed is ripe it should at once be sown thinly in pots, and the pots may be stowed away under a hedge or in any quiet place for two or three years, when a rich store—quite a treasure trove—will be found ready for planting out.—G. F.

International Potato Show.—The Committee have obtained from the Alexandra Palace Company a contribution of £30 to the prize fund, and have arranged to hold the show in the Alexandra Palace on the 29th and 30th of September next. As the amount of prizes offered exceeds £100, and many expenses must be incurred in securing a really representative exhibition, it is hoped the necessary funds will be forthcoming. The Committee have the assistance of Mr. Alderman Ellis as President, and Mr. James Abbiss as Vice-President. The Treasurer is Mr. James Crute, 88, Watling Street; the Hon. Secretary Mr. Peter McKinlay, 23, Upper Thames Street.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CULTURE OF THE AMERICAN DOG'S-TOOTH VIOLET.

(*ERYTHRONIUM AMERICANUM.*)

THIS interesting plant formerly grew in the open border here, but its flowers were rarely seen. Some years ago I put a tuft of the bulbs in one of the stone compartments of the rock garden having a southern aspect, the soil being a mixture of peat and loam. As soon as the space became filled with roots flowers were freely produced, and on the 20th of April it was covered with yellow blooms. In these confined spaces the bulbs are better matured for flowering than they can possibly be in open borders, where the surface of the ground is generally seen covered with a mass of small green leaves proceeding from numerous unmaturing bulbs, having but few of the larger spotted leaves which generally accompany the flowers. All the species of *Erythronium* succeed well in rough stone boxes. We have now in flower the true *Erythronium giganteum*, *E. giganteum roseum*, and *E. grandiflorum*, while the flowering of *E. Nuttallianum*, and *E. Dens canis*, cultivated amongst the stones, is just over. Many of the latter, however, are still in bloom on the northern grassy slopes of the rock garden; they were thickly dibbled in, here and there, when the turf was first laid, and, being placed in all exposures, a longer flowering season of these interesting plants has been obtained. In such places they do not seem to multiply fast, as single flowers proceeding from the two or three spotted leaves are only produced. Owing to the beauty which these plants present, when grown on Grass lawns, they should be more employed than they now are for culture in that way. When grown in beds and kept undisturbed (unless for sub-division) they are all very well, but, when grown in borders, as is usually the case, the roots are frequently tossed about by the spade, and come up in all directions. Judging from the flowering of the *Erythronium americanum*, when their bulbs are matured in stone boxes, roots planted in moderate-sized flower pots, and placed under the surface of the soil in the open border, ought to produce flowers in exactly the same way as in the rock compartments, provided they are placed in a position where the bulbs can be properly matured. I ought to have stated that, in Grass banks with a southern aspect, the leaves are all ripened off before the first Grass cutting takes place, which is not the case on Grass slopes having a northern aspect.

Royal Botanic Gardens, Edinburgh.

JAMES M'NAB.

BEST KINDS OF VEGETABLES.

FOR cropping a garden, be it large or small, but few varieties of each kind of vegetable are needed; and it is a well-known fact that gardeners stand, as a rule, by their old acquaintances year after year, and usually disregard all much-belauded introductions put forward annually, which are often only old friends in a new dress. I freely acknowledge, however, that there have been some useful introductions brought forward now and then, although, speaking generally of vegetables, the old are as good as, if not better than, the new. Beginning with Broad Beans, can three better kinds be named than the English Long-pod—which has been known under many synonyms, and of which Carter's Mammoth Long-pod appears to be a selected variety—the Green, and the Broad Windsors? Some varieties, such as the Mazagan, may be a little earlier, but for general crops these named are not surpassed. Of Kidney Beans, Osborn's Forcing is good, and is one new introduction that has borne out its character. The next best are Sion House—if it can be had true—Fulmer's Forcing, Long-podded Negro for a general crop, and Newington Wonder. Hitherto, the three last-named have supplied all our wants for years. Among Scarlet Runners, Carter's Champion is perhaps the largest variety; but the old Scarlet well grown, I have always found to satisfy the most fastidious tastes. Of Beets, Dell's dark-leaved variety will satisfy anyone, whether used for salads or for the flower garden. This variety, which was amongst the first, if not the first, of the true dark-leaved section, keeps to its character, and is a good kind, making good roots and dwarf tops. Amongst Borecoles or Greens,

the Dwarf German Curled is about the best, when true; otherwise the common Cottager's Kale leaves little to be desired. The quality of Greens depends a good deal upon cultivation; subjected to high culture they are coarse, but, grown on moderately poor soil, the leaves are better curled, fewer, and more tender. The Broccoli list of some catalogues enumerates not less than thirty-three varieties. Of these, the following selection will meet all requirements:—Walcheren, entered in catalogues both as a Broccoli and a Cauliflower, is the best to succeed the Broccoli till late in autumn, and is quite as good as Grange's Early Broccoli, if not superior to it. After this comes White Cape, Early Purple Cape, Snow's Superb Winter White, Osborn's Winter White, Chappell's Cream, Dilcock's Bride, Hammond's Imperial Hardy (a distinct sort), Knight's Protecting, Early Penzance, Shearer's Late White, Gordon's Late White, Wilcove Superb, and, for the latest of all, and of which a quantity should be planted, Carter's Champion and Cattell's Eclipse. These will afford a succession till Cauliflowers come in. Among Brussels Sprouts, Scrymgeour's Giant is a long-legged and abundant cropper; and Dickson's Sprouts and the Imported Sprouts are the best. The Dalkeith variety comes true, and will suit those who like the Sprouts large and firm. Of Cabbage I count in one seedsman's catalogue, where "the most useful varieties only are given," no fewer than twenty-five different sorts; but the old Enfield market supplies our wants throughout the year, with Dwarf York or Little Pixie for early crops. Our selection of Cauliflowers is restricted to Early London and Walcheren, after trying most of the kinds recommended. The first is excellent for early or general crops; and the second, though not so white as some, is the hardiest Cauliflower with which I am acquainted, and the least liable to "button" in dry seasons. Veitch's Giant and Grange's Autumn are, for some, too large-headed. Concerning Celery there is much diversity of opinion. I grow only one red kind, Lawson's Superb Crimson, one of the best-flavoured, hardiest, and least liable to go to seed I ever grew. It is also dwarf, the leaves attaining great thickness and substance, which gives solidity to the heads. Of white kinds, the Crystal is very good. There are few or none of the Celeries, however, that are bad, and different sorts succeed in different soils. Endive, of which we want a hardier variety, has not received much attention from improvers. At present, Green Curled and Digswell Prize are the two best. The list of Leeks is also short; Musselburgh and Henry's Prize are first-rate. I now come to Lettuces, of which a long list encumbers some catalogues. For summer crops, the Paris white Cos is still unsurpassed; and the same may be said of its associate, the Neapolitan Cabbage Lettuce. I have tried many sorts, but keep to these two. For winter and spring, the Bath Cos and hardy green Hammersmith are amongst the best. The last is still one of the hardiest, earliest, and most tender, but goes to seed quickly if starved. Of Tomatoes, the common Large Red, Trophy, and Orangefield are the best. Onions form another long list of nearly thirty kinds. The best are Danvers's Yellow, James's Keeping (difficult to get true, and the best keeper), Deptford, Strasburg, White Spanish, Silver-skinned (a kind used for pickling), New Queen, and, for autumn sowing, the Tripoli. Nuneham Park, a variety of the White Spanish, is difficult to grow in some places with a small neck. James's Keeping, Yellow Danvers, and White Spanish are good kinds for the main supply. In some lists no fewer than sixty-five varieties of Peas, or rather names, are given; and I suppose, if all were enumerated, about one hundred sorts would be found in the market. The following are very generally grown and approved—Early: Ringleader (otherwise First Crop or Dillistones) and Daniel O'Rourke. Early Wrinkled Marrows: Advancer, Little Gem, and Alpha. Second early Round kinds: Auvergne, Early Emperor, Laxton's Supreme, Essex Rival, Dickson's Favourite, Wrinkled Marrows: Superlative (new), British Queen, Ne Plus Ultra (old, but unsurpassed), Veitch's Perfection, and Champion of England. I think it unnecessary to extend this list, and at present I say nothing about the most recent introductions. Passing on to Savoys, I would recommend autumn-sown plants of Drumhead for a general crop where the demand is extravagant for autumn and Winter Greens, and for other purposes Green Curled or Ulm. The list of Turnips is moderate. White Dutch is still the best for early crops, being the least liable to run to seed; and it should be in every sowing during the season, as it is liked for its colour and tenderness. Early Snowball is also good; but for succeeding the White Dutch, I like the American Strap Leaf. Orange Jelly is a fine yellow-fleshed Turnip, perhaps one of the best to eat; but it is used comparatively seldom, the colour not being liked. For winter crops Chirk Castle is the best, being very hardy and tender fleshed. I come now to Potatoes. Of early kinds and Kidneys, I still find Mona's Pride to be one of the best, and a good forcer; next to it is the common Ashleaf, Veitch's Ashleaf, and River's Royal Ashleaf; and to succeed these the old Lapstone. Early Rounds:—Handsworth Seedling is one of the best for forcing, but is inferior to

many in quality. Rector of Woodstock is also a good useful kind. For a second early main crop I have never grown any kind but Dalmahoy, a variety too little known in England; for an immense cropper and general good qualities it is one of the very best—but it is liable to disease; still I grow more of it than any other every year. Of late kinds, Regent's Paterson's Victoria, and the Fluke, are still the best. J. S. W.

THE CARROTS.

By D. GUIHENEUF.

THE Carrot grows wild in England and in many other temperate countries. The root is spindle-shaped, whitish in colour, from 2 to 3 inches long, and $\frac{1}{4}$ to $\frac{1}{3}$ of an inch thick, and has a strong smell. The flesh is whitish, fibrous, and insipid; leaves radical, elegantly divided in bipinnate leaflets, terminating in acute segments. The stem is about 2 feet high, and produces, from June to October, beautiful umbels of white flowers, the central one being abortive, and of a dark red colour. When seed is matured, these umbels assume a bird's-nest shape, which has given rise to the popular name by which the plant is known, viz., Bird's-nest. The seed is a greenish brown, four or five-ribbed, and covered with prickles. It possesses a strong but agreeable smell, and is frequently used in medicine. This plant is widely distributed over calcareous districts, in meadows, pastures, grassy banks, and by roadsides. It abounds in deep sandy soil, but is rarely found in poor ground, and these facts must be well remembered in cultivating the garden varieties. This root has been cultivated from the remotest times; for so long a time, in fact, that not even an approximate date of its first occurrence can be fixed. This has led many eminent horticulturists to believe that the garden varieties and the wild Carrot are two distinct species; but many powerful arguments can be advanced against such a theory. Firstly, no other wild plant but the *Daucus carota*, or wild Carrot, has been found that could have produced such roots, there being not the slightest botanical difference between them, even the scent of both the seed and the root being equally strong and identical in character in both plants. Secondly, the ancient Greeks and Romans cultivated Carrots, which led some authors to argue that the garden Carrot was a native of Southern Europe; but it is quite natural that the extraordinary skill and intellectual superiority of the Greeks should have enabled them to improve the wild Carrot with success, and to obtain roots similar to those now cultivated with such care all over the world. From Greece it soon found its way to the islands in the Mediterranean, as well as to Italy and Spain, in which country it has been cultivated for very many centuries. Then sprang up the celebrated Candie Carrot; but the famous Gerard hit upon the truth when he alleged that the Candie Carrot was not only grown in Candia but was found wild on the mountains of Germany, France, and Switzerland; had Gerard persevered in his researches, he would have found it growing wild in England as well. Another proof of the origin of our cultivated Carrots is, that roots similar to the garden kinds have lately been obtained from the wild Carrot by the late M. Louis Vilmorin, who, after several skilful selections, succeeded in giving fixity to many varieties of different colours, which are now well fit for table use. It has been said that the flesh of these new Carrots was more fibrous and less well flavoured than that of the old varieties; but, when they have had the advantage of as lengthened a period of cultivation as the older kinds, they will probably be as fine as, and perhaps superior to the latter. Although Miller says that, after cultivating the wild Carrot during twenty years, he did not see any improvement, it was no doubt because he did not act throughout with the necessary care, such selections requiring a good deal of patience, knowledge, and skill. Thirdly, by going attentively through a field of Carrots, especially the white and yellow varieties, many plants will be found showing a tendency to return to the wild kind, and this is commonly the case with the long purple Carrot. As a

Root of the Wild Carrot (*Daucus carota*).

proof of this, it may be mentioned as an established fact that, if a single root of the best sort be planted in a field among wild Carrots, the produce of the seed the following year will have much degenerated, and, should the worst plants of the seedling be selected and submitted to the same process for many years, the entire stock will, in course of time, completely revert to the wild Carrot type. Gardeners are well aware of this, and are very careful in planting their seed-bearing stock. The leaves of the Carrot are very ornamental; it is said that they were formerly used for adorning ladies' hair. If in winter a top of a Carrot be cut and placed in water under glass, leaves will spring up that are similar in appearance to a Fern, and are valuable for decorative purposes. Artificial flowers are also made from roots of the cultivated Carrot, and vegetable Ranunculuses may thus be obtained without any colouring. These flowers look very pretty on dishes on a dinner-table, and others similar in character may be obtained from Beetroot, Radishes, and Turnips.

Uses.

The Carrot is one of the most useful plants in domestic economy, inasmuch as it furnishes throughout the whole year a vegetable that is both wholesome and palatable. Its uses are very various, and it is found alike on the tables of the rich and poor. Its culture, too, is by no means difficult, and its produce, although generally inferior in quantity to that of Mangel, and sometimes of the Turnip, is superior to these roots in nutritive qualities; it is, however, no uncommon circumstance for an acre of White Green-topped Belgian to yield 25 tons, which is a larger crop than that of either Beet or Turnip frequently is. The saccharine matter contained in the Carrot amounts to 8.5 per cent. of its weight; but all efforts made to take advantage of this fact have hitherto failed. The quantity of sugar in Carrots varies according to soil, culture, and climate; and in those produced under a southern sky, saccharine matter is doubtless more abundant than in those grown in less sunny latitudes. If a Carrot be cut transversely, it will be found to consist of two parts; the exterior or rind, which is deep in colour, and which is the most tender as well as the most nutritious part, and the interior, which is of a paler shade, and always more or less fibrous and insipid in taste. It is the last-mentioned part that cultivators should strive to reduce by means of skilful hybridisation; and, in order to make certain that a good selection has been made, the lower part of the root of the selected plants may be cut off, and the remaining part examined and replanted. The French, who are the most difficult to please in respect to this vegetable, never make use of field varieties for cooking, except in cases of necessity. In France, also, where its cultivation is most extensive and the best carried out, all the known varieties are more or less made use of according to their value; but the culinary kinds are grown everywhere, even by the poorest people. Belgium, although having originated several varieties, is still far behind as regards varieties of the Carrot, inasmuch as several field kinds are still largely used there for culinary purposes. However, the culture of each variety is carried to perfection in that country. The celebrity once enjoyed by Holland for the production of seed of this vegetable, which was due to the climate and the soil, has much diminished of late years. In some parts of Germany its culture is carried on upon a large scale, but not generally so. One great fault of the latter country in respect to Carrot raising is that in almost every province the same varieties are found under different names; for example, the Frankfort, Erfurt, and Brunswick kinds are simply common varieties under these titles. England is in all respects the most backward in the culture of Carrots—for culinary purposes at least. The varieties grown in this country are less numerous, inferior in quality, and badly grown, compared with French kinds. In gardens this is most observable, and the consequence is the London markets are stocked chiefly with the Surrey Carrot, a tough variety, without flavour, and with a heart sufficiently woody to make a walking-stick. It is, moreover, difficult to cultivate, on account of the deep soil that it requires; while, on the other hand, the finer cooking varieties accommodate themselves thoroughly to soils of medium depth.

French Forcing Carrot (*Carotte très-courte à châssis*).—A French variety, the smallest and earliest Carrot, chiefly used for forcing. It is a great favourite among the Parisian market gardeners on account of its extreme earliness. The root is from $1\frac{1}{2}$ to 2 inches in size, nearly round, and terminates in a very fine tail. It is pale straw coloured when grown under glass during the winter, but scarlet when raised in open ground. The flesh is very tender and finely flavoured; and it has scarcely any heart. The top is greenish and hollow-crowned; the leaves few and small. This variety is extensively used on the Continent, and its cultivation ought to be much more wide-spread in England, affording, as it does, all the year round, a fair supply of fresh Carrots. Anyone visiting the Halles Centrales at Paris, in spring time, cannot fail to notice the cart-loads brought every morning by the market gardeners to that market, as early as February. Recently, bunches of this variety have made their appearance in Covent Garden Market, but the freshness of such tender roots is spoiled by their journey from Paris to London. The annexed out is the true shape, and of the

Early French Forcing Carrot.

natural size, but inferior stocks producing conical roots neither so succulent nor so early, are often met with. This valuable Carrot ought to be used only for forcing, and should never be grown in the open ground. Sowings should be made on hotbeds having a medium temperature, from November to February, for use from February until May. For early crops sown in warm borders, however, the Scarlet Horn will be found to be far better adapted. Market gardeners sow the Early French Forcing Carrot in August and September, and, after protecting it in winter, sell it in the spring for newly-forced Carrots, to which they bear some similarity after a sharp brushing before they are sent to market, but the difference may be easily detected by their deep scarlet colour, and the leaves being entirely stripped off. In addition to this, the skin is rough and the flavour much inferior, whilst newly forced Carrots are smaller, of a straw colour, with a shining skin, and are always tied up in bunches by their long thin leaves; both may now be seen at Covent Garden. Special attention should be paid to this variety, which really deserves general cultivation. The following are its synonyms—French Forcing Carrot, French Forcing Horn Carrot, Very

Early Forcing Carrot, Very Early Scarlet Horn Carrot, Very Early Short Horn Carrot, Early Forcing Horn Carrot, Very Early French Carrot, &c. French; *Carotte grelot*, *Carotte Très courte à forcer*, *Carotte Carline*, *Carotte toupie*, *Carotte à châssis*. German; *Möhre—allerkürzeste früheste zum treiben*, *M. sehr kurze stumpfe früheste zum treiben*.

Scarlet Horn (*Carotte rouge courte*).—A popular early variety, the most generally cultivated for the first crop in the open

Scarlet Horn.

Intermediate Scarlets.

ground. The root is deep scarlet, $2\frac{1}{2}$ to 3 inches long, and 1 to $1\frac{1}{2}$ inches thick. It is nearly cylindrical, slightly tapering, and terminates abruptly. The flesh is very tender, and highly flavoured. The top is greenish, and hollow crowned; and the leaves of a medium size. It can be used for forcing exactly like the preceding kind, but being of a larger size it is not quite so early, therefore the best time for sowing is in February, on a warm exposed border; and, if well protected, in case of severe weather, a fair crop of new Carrots may be expected by the beginning of May. Sowings made subsequently from March to May will afford a fair supply during the whole summer where large roots are objected to. On account of its small size it is not suitable for winter storing. This kind is often mistaken or sold for the last-mentioned, although the two plants differ much, both in size and earliness. The following are its synonyms:—Early Horn Carrot, Early Scarlet Horn Carrot, English Horn Carrot, Dutch Horn Carrot, *Carotte rouge courte hâtive*, *Carotte rouge courte d'Hollande*. &c.

Intermediate Scarlet (*Carotte rouge demi-longue pointue*).—The best variety for general use; it has beautiful scarlet roots, 5 inches long and from 2 to $2\frac{1}{2}$ inches thick, tapering and sharp-pointed. The flesh is highly flavoured and of the best quality. The top is greenish, hollow crowned, with a few vigorous medium-sized leaves. This excellent kind ought to be grown for the main crop in every garden, as it is very hardy and a large cropper. It is the best and the most useful kind for winter storing; it grows in almost every kind of soil, and, provided the plants are kept at a sufficient distance apart, it will resist drought better than any other garden kind, besides losing little or nothing of its valuable properties. Sow from March until June, in rows from 9 to 12 inches distant. Thin the plants as soon as possible, and keep them from 4 to 5 inches apart, according to the quality of the soil, as soon as they attain the size of a pencil. Hoeing and watering, in case of extreme dryness, will aid development and ensure a good crop of excellent Carrots. It is known under a great many names, according to the country in which it is grown; and, on account of its productive qualities, it has been cultivated sometimes in the field, where from 14 to 15 tons of roots have been produced to the acre.

Intermediate Scarlet Stump-rooted.

Intermediate Scarlet Stump-rooted (*Carotte rouge demi-longue obtuse*).—A French variety, similar to the last described in its quality and uses. The root is deep scarlet, from 4 to $4\frac{1}{2}$ inches long, from $1\frac{1}{2}$ to 2 inches thick, and almost cylindrical in shape. The

root is stumped, the top greenish in colour and hollow crowned. It is an improvement on the preceding kind, which it has supplanted in many gardens, though less hardy and occasionally more affected by drought. It is a valuable variety for autumn and winter storing. It has enjoyed a popularity in France extending over thirty years, and is now much used in America, Germany, and Belgium; but its introduction into English gardens has been very gradual and partial. It requires the same culture as the Intermediate Scarlet Carrot, and is an exceedingly valuable kind that should, if possible, be always added to the list of winter vegetables.

Intermediate Nantes Scarlet (*Carotte rouge demi-longue Nantaise*).—This is of recent French introduction, having a close analogy to the two preceding varieties. The root is a deep red in colour, $4\frac{1}{2}$ inches long, from $1\frac{1}{2}$ to 2 inches thick, and bluntly cylindrical in form; the top is greenish in colour, with a hollow crown. The leaves are of a medium size; the flesh is very superior in flavour and quality, the heart being far less developed and much more tender than in other varieties, and both for sauces and stews it is a most desirable kind. It is a most valuable acquisition to the kitchen garden, and it may be said that its value is thoroughly appreciated, for its cultivation has become very extensive for the short period during which it has been known. Although it is an earlier variety than the two preceding ones it is not sufficiently so for forcing. Sown from March to June it will produce an excellent crop in the autumn and throughout the winter. On account of the delicacy of

Intermediate Nantes Scarlet.

James's Intermediate.

this Carrot, considerable attention and care must be devoted to it during its growth, which will be amply repaid by the results. It is also called *Carotte sans cœur*.

James's Intermediate Carrot.—This is a favourite in English gardens. The root is scarlet, is 6 inches long, from 2 to 3 inches thick, and conical and sharp-pointed. The top is green, flat, and not hollow-crowned; the leaves are vigorous, the flesh scarlet and of good quality. This hardy variety grows almost in any soil and stands bad weather well. It keeps well and is, therefore, suitable for winter use. It should be sown from March to May in rows 12 inches distant, leaving the plants 4 or 5 inches apart. On account of its large producing capacity it is sometimes grown as a field crop. This variety is probably the French Intermediate Scarlet which, after many years cultivation in deep rich soil, has assumed other characteristics, for the two varieties are now perfectly distinct both in shape and quality, the latter being somewhat smaller and more tender, and the form of the top being strikingly dissimilar. It is an excellent variety for small gardens which receive little attention.

Intermediate Luc Carrot (*Carotte demi-longue de Luc*).—This is a variety of the preceding which has been in the markets for a year or two. It is of medium size, and it combines the qualities of the Nantes kind with the earliness of the Scarlet Horn. The root is a deep red in colour, and bluntly cylindrical in shape. The leaves are very small. It has, like the Nantes variety, little heart, and is very early; it is consequently fit for forcing. If the accounts given of the advantageous qualities of this variety are not exaggerated, this is another excellent addition to the best kinds, uniting earliness and good quality, and therefore it is preferable to the Early Horn.

Altringham.—An English variety, readily distinguished from any other. It is said to have originated about sixty years ago, at Altringham, a village in the vicinity of Chester. Root, slender, somewhat crimped, from 9 to 12 inches long, and from $1\frac{1}{4}$ to $1\frac{1}{2}$ inches thick. In shape it is cylindrical at the upper part, tapering to a point at the lower end. In colour it is of a beautiful red, with a green conical top, showing about 1 inch above ground. The flesh

is of the first quality, deeply coloured, and almost without any fibres. The heart is much reduced, comparatively speaking. This variety was much used for colouring butter before the discovery of Annotto. On account of its good qualities it is often used for

Altringham.

Long Red.

cooking, for which purpose it is far preferable to the Surrey, but both these varieties should in all gardens make room for the more delicate-flavoured intermediate kinds. Sowing should be made from March to the end of May, according to the climate and weather; heavy soils must be avoided as much as possible, the fragile character of the root rendering it difficult to pull. Twelve-inch drills and 4 to 5 inches between the plants are sufficient to obtain a fine crop. Other and less valuable kinds are often supplied for it. This variety is known also under the following names:—Long Red Altringham, Superb, Cheshire, Green-topped, Rouge longue d'Altringham.

Long Red (*Carotte rouge longue*).—This is an old standard variety, the root of which tapers gradually, and is almost entirely buried in the ground. In colour it is a deep orange; from 9 to 10 inches in length, and from $1\frac{1}{2}$ to 2 inches in diameter. The top is flat, and occasionally green; the flesh is yellowish inside, and the heart of a moderate size, but tolerably hard. It is the most succulent field variety, and is still used in English, Belgian, German, and American kitchens. The size and shape of the root is very variable, according to the soil and the climate, sometimes assuming a shorter and thicker form, which ought to be preferred. This variety may be occasionally seen among the Surrey Carrots in Covent Garden. It should be sown in deep soil, in 15 inch drills, the plants being thinned to 5 or 7 inches apart. On account of its colour it is often called the Long Orange Carrot, and also the Studley.

Long Lemon (*Carotte jaune longue*).—This is seldom cultivated. The root is pale yellow, and spindle-shaped; slender, from 8 to 10 inches long, and from $1\frac{1}{2}$ to 2 inches thick. It is generally completely concealed in the ground, but sometimes has a top of $\frac{1}{2}$ an inch, which is green. The flesh is cream-coloured, sweet-flavoured, and of good quality; it is a moderate cropper, but a good keeper. It is confined to some provinces, and will never come into general use, other kinds being far preferable. Sow from April to June in deep sandy soil, in 12-inch drills, and thin the plants 4 or 5 inches apart. It is only useful as food for horses, cattle, or sheep.

Short Lemon (*Carotte jaune courte*).—A variety of little use, and very seldom cultivated. The root varies considerably in shape. It is pale lemon in colour; 4 inches long, from 2 to $2\frac{1}{2}$ inches thick, tapering, is generally surrounded with other small roots, and does not grow above ground. The flesh, of a medium quality, is often coarse, whilst the top is hollow crowned. The leaves are dark green, trailing on the ground. Properly speaking, it is not a selected variety, for similar roots can be obtained from the wild Carrot after a few years selection.

Long Surrey.—These beautiful roots are grown in, and brought from, Surrey and other counties; the deep soil required for their full development rendering their cultivation about London unprofitable. The root is a deep orange colour, from 16 to 20 inches long, and from 2 to 3 inches in thickness at the level of the ground. It is very slender, and the longest of all the Carrots, and grows entirely in the ground. The top is flat, and the base of the foliage large and swollen by the decay of old leaves. The only valuable quality of this variety is its capability of keeping in a perfect condition almost the whole year through, the woody, fibrous texture of its flesh resisting every injury. Even the heart, which is fully developed, does not become tender by boiling; yet it is a favourite vegetable, and is daily used in English kitchens; and the large quantities brought to Covent Garden during the winter attest that Carrots of a fine quality are little known in London. The Surrey is a field variety wholly unfit for the table, though, doubtless, it will continue to find its way there for a long time, its abundant crop permitting the grower to sell it cheap, and its fine appearance being favourable to its sale. Its probable origin was the Long Red variety in the deep soil of some part of England, but these two kinds are perfectly distinct now, though the seed of one is often sold for that of the other. The Brunswick, so much cultivated in Germany, is similar to this variety. Sow from March to May, in deep-trenched soil, keeping the plants at a fair distance from each other.

Green-top Long-red (*Carotte rouge longue à collet vert*).—The root of this variety is orange coloured; from 12 to 15

Long Surrey.

Green-top Long-red.

inches long, and 2 inches in thickness. In shape it is cylindrical and slender at the lower part; 2 or 3 inches of it grow above ground, and this part is of a greenish-brown. The top is conical, and the flesh orange-coloured. It is fragile, productive for field culture, and growing so much above ground is easily pulled, advantages much appreciated by cultivators. Though known, comparatively speaking, but recently, it is largely cultivated in France, Belgium, Germany, and America, and will certainly become a popular variety. It is very hardy, and grows well in every kind of soil, but does not keep well. It must not be grown in gardens, being fit only for field culture. On account of its yellow-red colour it is known under several names, according to the country in which it is grown; for instance, Orange Belgian, Large Orange Belgian, Orange Belgian Green-top (America); Möhre grünkopfige riesen (Germany). It should be sown from April to May in 15-inch drills, the plants being kept 5 to 6 inches apart.

White Breteuil (*Carotte blanche de Breteuil*).—This is grown in some localities only, and is of little use. Its root is 7 inches long and 3 inches thick, cone-shaped, tapering, and sharp pointed.

It is crimped and neat in shape, and grows altogether embedded in the soil. The top is flat and somewhat sharp-edged. The flesh is of a better quality than that of the White Vosges, described below (of which it is a variety), and it succeeds equally well in shallow soils, and keeps well.

Red pale Flanders (*Carotte rouge pâle de Flandres*).—This old French variety, that used to be largely cultivated, has lost much

Red pale Flanders.

White Vosges.

of its celebrity, its cultivation being confined to some localities only. It is certainly the hardiest, and keeps the best of all the Carrots; it is of a variable quality, has a pale red root that is conical shaped, slender at the lower extremity, and grows entirely in the ground. The heart is very large; the top flat, and almost covered by the basement of the leaves, which are strong and vigorous. It will grow anywhere, even in the poorest soil, and will remain long fit for use after other sorts have disappeared. It is only fit for field culture, but in no case does it deserve very extensive cultivation.

White Vosges (*Carotte blanche des Vosges*).—An old French variety, much praised some fifty years ago, but now only cultivated locally. The root is conical, tapering, sharp-pointed, and from 5 to 7 inches long, and 2 to 3½ inches in diameter. Its colour is whitish-yellow, and the root is wholly below ground, except occasionally a small greenish top. The flesh is firm, very variable in quality, and sometimes woolly. This is a good variety for heavy or shallow soils, and will succeed in the poorest, where other kinds will fail. It is often used in the kitchen late in the spring, being a good keeper.

Belgian White Horn or White Transparent Carrot.—A very curious and interesting variety of the White Vosges. The root varies much in size and shape, but is usually from 4 to 5 inches long, and from 1 to 2 inches thick; it is spindle-shaped, slender, or conical, and grows completely buried in the ground, with a white and very tender smooth skin. The flesh is white, transparent, fine grained, and of superior quality. It is a good Carrot for the kitchen, but objected to on account of its transparent colour. It is the *Carotte blanche transparente* of the French.

The Purple Carrot (*Carotte violette*).—This is a singular variety, now much less cultivated than heretofore. Its origin is very uncertain, but its introduction into France is attributed to Baron de Bendanna, who is said to have brought it from Spain, although one of its French names (*Carotte noir de l'Inde*) seems to assign to it another birth-place. Amongst Carrots that have a tendency to degenerate are often found roots that bear much resemblance to this variety, so far as colour and form are concerned. They are, however, always somewhat smaller and less savoury. The root is fusiform and tapering, 10 inches long, and from 1½ to 2 inches in diameter, but sometimes growing to an unusual size; and of a deep violet colour. The flesh, which is fine in the grain, is of a violet tint, but yellow or yellowish at the centre. It contains a great deal of sugar, and its quality varies very much. The leaves, which are of a deep green, grow horizontally. Its use for culinary purposes is very limited, on account of the disagreeable colour which it imparts to sauces in which it is used. It grows well in damp soils, and should not be sown before May, or the plants are apt to run to seed. In fact, its culture offers few advantages. It is also known under the name of Deep Red Carrot.

Green-topped White Belgian (*Carotte blanche à collet vert*).—A standard variety of Belgian origin, well deserving its high reputation. The root is whitish, from 12 to 14 inches long, and from 2 to 3 inches thick, bluntly tapering; a third part of the entire length grows above ground, is entirely green, and is rounded off towards the top. The leaves are dark green, large, and vigorous; the flesh white, of a good quality, but is never used in France for either soups or seasoning, as stated in some American reports, but appears to be appreciated in English cooking. This is a mammoth variety, and the largest cropper of all the Carrots, often producing 20 to 25 tons to the acre, besides being very hardy, and easily pulled. It is extensively used in field culture all over the Continent, no other root being of greater assistance to the farmer in keeping his live stock in condition through the winter. The Red Horn Carrots contain, it is true, a much larger proportion of nutritive matter than this kind, but they are so inferior in productive capacity that no advantage is gained by giving them the preference over the White Belgian for field cultivation. The time for sowing the latter varies according to the soil and the state of the weather, from April to the beginning of June; if later, the roots have no time to attain their full growth. In some countries the leaves are cut down two or three times to within a couple of inches of the top for green food for cattle, but this practice is very injurious to the roots and ought to take place only once, and then only a few days before pulling up the crop; 15 inch drills, and the plants 5 or 6 inches apart, is generally sufficient room for this kind. The stock of this Carrot is generally bad, and its cultivation is not understood in England. A fine specimen root is seldom exhibited anywhere. Its synonyms are large White Belgian Carrot, and White Green-top Belgian Carrot.

Green-topped White Belgian.

White Orthe (*Carotte Blanche d'Orthe*).—A variety of the preceding kind, held in great esteem by all who have tried it, though it has not been long in general cultivation. The root is cream coloured, 10 or 14 inches long, and 2 or 3 inches thick, cylindrical, and bluntly tapering at the lower extremity. It grows entirely embedded in the ground, or with a 1 inch top, which is greenish and flat or slightly conical. The flesh is white, and of better quality than that of White Belgian. The annexed cuts represent two forms of this Carrot, and show its affinity to the last-mentioned variety, to which it is superior in succulence and fleshiness. It is an excellent variety, a large cropper, with roots beautifully shaped, but requires a good soil to develop it thoroughly. It deserves to be largely cultivated, and should be sown from March to May for agricultural purposes only.

Wild Improved.—Varieties have, as previously stated, been obtained from the wild Carrot by careful selection; their shape and quality are not yet fixed, and vary according to circumstances. Its red, white, and yellow varieties, which are occasionally cultivated, are said to resist drought better than common sorts, besides being very hardy. The flesh is firm, sweet, of a good quality, and fit for kitchen use. In size they are something like the Intermediate Scarlet, but are more conical in shape. From such varieties, all other kinds might be obtained; but the result would probably be only a reduplication of the existing kinds, and consequently of little value.

Carrot Seed.

On account of its numerous bristles, Carrot Seed is somewhat difficult to sow with regularity; therefore, it is mixed with sand or dry soil. This difficulty is obviated now by buying clean seed from seedsmen—a practice carried on on the Continent long before it was in England. Laying the seed in wet sand or wet loam a few days before sowing, in order to stimulate germination, was once much practised; but, partly from the trouble, or partly from want of skill, this method is now seldom employed. It may, however, prove advantageous under some circumstances; for instance, in forcing and sowing in the open ground, where drought is to be apprehended. In the United States, it is the practice to soak the seed in tepid water

for a day or two, and then to mix it with plaster or ashes. Carrot seed retains its vitality for four years; but if not threshed out, and stored in its umbels, it will last five, or even six, years.

Cultivation.

Carrots require a deep, light, warm soil; well trenched, and previously well manured. Sowing must be effected in dry weather; for, should a shower happen soon after the seed is in the ground, the crop will, in most cases, be a failure, if not sown again immediately. Drills ought to be preferred to broadcast sowing, there being no possibility with the latter of attending to the crop conveniently.

Forcing Carrots.—The French Forcing and the Scarlet Horn Carrots are the best for this purpose, but the first is to be preferred. Prepare mild hotbeds 2½ feet high in November or December, and 1½ or 2 feet in January or February; put on the frames, cover the bed with 5 or 6 inches of rich soil or mould, and, as soon as the whole is sufficiently heated, sow the seed broadcast, cover with half-an-inch of mould, smooth the surface, and cover the glass with mats until the seed comes up. Should the interior get dry, give a slight watering, but be careful of damp. When the plants have four or five leaves thin them half-an-inch apart; admit air as often as the temperature will allow of it, which will give strength to the seedlings. Take care the heat does not exceed 60° during the day and 50° at night, which may be easily regulated by tilting the glass. In the case of sharp frost covering with mats is preferable to artificial heat. Shading, if needed, must not be omitted. Sowing in November, if carried on by practical men, will produce fine young Carrots at the end of February, which will last through March and April. Subsequent sowings—in December for March to April, in January for April to May, and, lastly, in February for April to June—must be attended to as required by market gardeners; but, in private gardens, the first bed should be made in November and the second in January; these will afford an ample supply until new open-ground Carrots are fit for use. Where frames are not available prepare, at the beginning of February, in some warm corner, a bed of hot dung mixed with leaves, covered with 4 or 5 inches of mould; sow the seed and protect with mats supported with sticks or other apparatus. As soon as the seed comes up remove the covering every day as frequently as

White Orthe.

the weather will permit, and the crop will be ready from the end of April to that of May. Parisian market gardeners mix seeds of Radish and Lettuce with those of Carrots, the former being ready for use before the Carrots, which are then left to produce a second crop, a practice not advisable, nor is that of planting Cauliflowers amongst forced Carrots.

Open Ground Culture.—For the first crop sow in February, on a warm, dry border, the Scarlet Horn Carrot, in 5-inch drills; cover the seed with half-an-inch of decomposed mould; when the young plants have formed a few leaves, clear off the weeds, and thin them to 1 or 2 inches apart, hoeing and watering as required. The crop should be ready by the end of May, and will last until the general crop comes in. In June sow the same kind of Carrot again, where small roots are preferred.

General Crop.—Intermediate Scarlet, Intermediate Stump-rooted, and Intermediate Nantes, are the three best varieties for general crops. Sow them from March to May (the latter month for winter Carrots) in well-prepared soil, in 9 to 12-inch drills, half-an-inch deep. As the Carrots make their appearance, hoeing, weeding, watering, and thinning them to half-an-inch apart, should be duly attended to. So soon as the plants attain the size of a lead pencil, thin them to 3 or 4 inches apart without hesitation. Thinning generally receives too little attention in every country; and the Carrots, crowded when young, are left to be taken up for use when they have attained sufficient size. In most cases, the ground gets dry and hard, and thus prevents the lifting of the roots, which are then left until the autumn, when only small, useless Carrots are the result.

Autumn Sowing.—In August and September, select a warm border. Sow French Forcing or Scarlet Horn Carrot, as for the early crop. The roots must remain in the ground the whole winter; but, if they are well protected and the bed is covered with an inch of mould, fine little Carrots will be ready from February until May.

Field Sowing.—No roots succeed better and are more easily cultivated in the field than Carrots. Select a rich soil, deeply trenched, and previously well manured. A little addition of salt will produce excellent effects. Sow from March to May, in from 10 to 15-inch drills, keeping all the plants 4 or 5 inches asunder, according to the variety. Weeding and repeated hoeings will ensure an abundant crop; but be careful in choosing dry weather for such operations.

Storing.

Garden Varieties.—In October, before the frosts occur, and on a fine day, take up the crop, cut the leaves $\frac{1}{2}$ inch from the top, clear the roots from soil, and store them at once in a cold cellar; there arrange them in tiers, spreading between each a layer of sand or dry soil, up to the height of 3 feet, the length being determined by the quantity of roots; two boards will secure the ends of the pile. By this means the roots can be easily and often examined, and those that are decayed removed. On the first symptoms of vegetation appearing, pull down the pile and build it again, and this method will enable the Carrots to be kept in a good state as late as possible. Another method—In open ground, in a dry place, remove the soil to the depth of 1 foot, trench the bottom, adding some sand if possible; plant the roots vertically close to each other, and protect from frost and from wet. The objection to this plan is, that decay cannot be attentively watched, and vegetation is much more liable to be excited, to prevent which the roots must be lifted and again buried. Heaps should be avoided in the case of garden varieties.

Field Varieties.—On a fine day take up the crop, clean the roots of soil, and store them in a cool situation beyond reach of frost, in moderate-sized heaps, which must be moved three or four times in the course of the winter to prevent fermentation and decay. However I have often seen Carrots harvested on a rainy day, and stored as taken up, keep until April, as fresh as in the autumn, provided they are kept cool. Cutting the top of each root as soon as harvested has been advised to prevent vegetation, but such Carrots do not keep so well as the others, and lose a great deal of their flavour; cutting the leaves right off the top, must be done to agricultural sorts only.

Disease and Insects.—Rust only is to be feared, and this occurs generally from the roots being grown in wet soil or having suffered from dryness in summer. Too much fresh dung will also provoke it. There is no effective remedy for it, but salt and quicklime applied to the ground before sowing is an excellent preventive as well as fertiliser. At spring-time, in hotbeds or borders, the young plants of the first sowings are sometimes entirely destroyed by a small spider. Gardeners watching young Carrots are surprised the next day to see that every plant has disappeared. Soot spread over the drills, or the entire bed, will effectually prevent such a disaster. Snails and slugs are very fond of young Carrots, one of them being able to destroy a small bed in a single night. Quicklime spread over the young plants (which it does not injure) and around the beds, will secure the crop; for it needs but to touch one of these insects with it, and it is instantly killed.

THE INDOOR GARDEN.

AMARYLLIS (HIPPEASTRUM) HENDERSONI COCCINEA.

THE coloured illustration which you have given (p. 346) of this *Amaryllis* is, to me, unusually interesting, as I have seen the plant, which is one of the most remarkable and stately among *Amaryllids*. The flower-stem, which has a delicate blue-green bloom, rises perfectly erect, to a height of 18 or 20 inches, and is crowned with two or three flowers, each measuring from 6 to 7 inches across. The marking of the petals is both unusual and striking. About half the petal, next the centre, is of a fine velvety red, terminating abruptly, with a few irregular freckles of the same colour, which extend for a short distance along the longitudinal veinings. The rest of the petals, to the points, is of a rich full cream colour, slightly shaded on the veins with a greenish tone, which is more conspicuous on the back of the flower than the front, except in the centre, where, at the base of each petal, a pointed ray of very vivid green is seen, forming a six-rayed star of great brilliancy. Messrs. Henderson have succeeded in raising two varieties of this splendid addition to the *Amaryllis* family, one having the dark portion of the petals of a deep crimson tone, and the other having the corresponding portion of the petals of a rich velvety maroon-scarlet. It is the last-named, and most brilliant, variety that you have figured. As in many of the *Amaryllis* family, the foliage does not attain its full growth till after the decay of the flower. Young bulbs are formed in a somewhat unusual way in this variety; they occur on the root-fibres, at some distance from the parent bulb, often at a distance of 2 to 3 inches. As soon as they have thrown out fibres of their own, the connecting link with the old bulb may be cut, when they grow independently, and, as soon as their foliage has died down, they may be removed and put into separate pots, and will probably flower in the second or third year. As a table ornament, a plant of this remarkable *Amaryllis* or *Hippeastrum*, placed in an ornamental vase, has a striking effect. It has formed one of the chief attractions of the Wellington Nursery during the early part of the present spring, where a number of plants of it, when seen in flower together, never failed to arrest attention. No collection of *Amaryllids* will henceforth be complete without it. H. N. H.

AUTUMN AND WINTER BLOOMING PLANTS.

Sericographis Ghiesbreghtii.—This is, perhaps, the most serviceable of all the winter-blooming plants, as it is easily grown, free-flowering, very effective, and stands well in a moderate degree of heat, very little, if any above that of an ordinary greenhouse, provided it is light and dry. The foliage, too, is of a most pleasing glaucous-green colour, setting off the light feathery scarlet *Justicia*-like flowers to great advantage. Few things are more effective than this *Sericographis* for grouping in jardinières or mixing with other plants, as it associates well with most on account of its light, easy habit of growth. For mixing with loose plants of *Deutzia gracilis*, or *Eupatorium ageratoides* it is most effective, and has done good service in the conservatory here, associated with these and other plants of similar character. Perhaps the most pleasing group has been a jardinière of this mixed with *Libonia floribunda* and *L. penrosiensis*, the latter a most interesting plant, the result of cross-breeding between the *Sericographis* and *Libonia floribunda*. It has exactly the leaves and habit, in miniature, of the *Sericographis*, while the flowers partake in an equal degree of the character of the two parents. The trio are invaluable for winter decoration, being very chaste and effective, and harmonising well together. The whole of them should be propagated at once, so as to form useful plants by the autumn. They strike freely at this season in close moist heat, and as the treatment necessary for the *Sericographis* will suit the *Libonias* also, I will simply treat of the former. The cuttings, when struck, should be potted off singly in the ordinary way, in a mixture of peat and loam in equal proportions, or, failing the peat, some well decomposed leaf soil may be substituted, to which should be added a small quantity of sand. The plants should then be replaced in moist gentle heat, and shaded on bright sunny days till they get established, after which they should be subjected to plenty of light by placing them on shelves near the glass. Continue to pot in the same kind of soil as they advance in growth. As the days lengthen the plants should be plunged in a pit or frame, in a bed of gently fermenting leaves. Here they will require slight shade during the summer on hot sunny days, but it should only be on for a few hours, and the plants should be well syringed and shut up early in the afternoon to induce them to grow freely. The ends of the shoots should be nipped out once or twice during the early part of the summer to

keep the plants bushy and compact, and towards the end of the season the lights may be removed for a few hours when the weather is favourable, to help to mature the growth. The *Libonia floribunda* flowers much more freely when treated in this way.

Rivina humilis.—This is one of the most useful and effective plants which we have for table decoration; and, by growing a few plants of it in succession, it may be had in good condition all the year round. Plants that bear berries are always prized for table decoration, as they associate better with the surroundings than do plants that bear bloom only. This has the double recommendation of bearing both fruit and flowers at the same time, and in the greatest profusion, even in the case of small plants. Unfortunately this plant has one drawback, and that is, after the berries attain a certain degree of ripeness they drop off a little too freely. For table decoration perhaps the most pleasing and effective are dwarf standards, with fine clean stems of a foot or so high, as in this way they show off their drooping bunches of rich-coloured fruit to the best advantage. Plants raised now, either from seed or cuttings, will attain a sufficient size for decorative purposes next autumn and winter; and, if required large for summer display, by means of a shift or two they may be grown to almost any dimensions. They are so easily and quickly raised from seed that it is scarcely worth while to propagate them in any other way. The seed should be sown in peat or finely-sifted leaf mould, and placed in heat to vegetate. As soon as large enough to handle the young plants should be potted off in small pots, and be replaced in moist heat to give them a start; as growth proceeds, all the lateral shoots should be pinched out till the plant attains sufficient height to form the stem, when the top may be stopped in like manner, leaving sufficient buds to break so as to form the head. In nipping out the laterals care must be taken not to injure the main leaves, or it will weaken the plant. As soon as the heads break fairly into growth the plants may receive their final shift into 6 or 8-inch pots, according to the size of the vases intended to receive them. They should then be placed in light airy positions to induce them to set plenty of fruit, which they generally do in a very free manner. During autumn and winter it will be necessary to keep them in a cool stove or intermediate house, in a temperature ranging from 50° to 60°. Should the heads become too large at any time, they may be cut back or thinned out to any extent, as they soon break freely into growth that blooms and fruits in quick succession.

Fuchsia serratifolia.—This fine old Fuchsia appears to be but little known, or its merits as a winter-blooming plant would bring it into more general cultivation. Unlike most of the Fuchsias, this is an evergreen variety, and flowers on the terminal ends of the shoots, much after the manner of that once popular old favourite *F. fulgens*. The leaves of *serratifolia* are of a peculiar metallic glaucous-green hue, a tint that sets off the rich pendulous flowers to great advantage. This variety has probably gone out of favour by being treated in the ordinary way and grown as a summer-blooming plant, at which season it is comparatively worthless, as it seldom shows a flower. Cuttings put in at once will make very useful plants by the autumn, and if kept during winter in a uniform temperature of 45° to 50° they will afford a continuous succession of bloom. In order to induce free growth, the plants should be potted on from time to time as required. The soil best suited for them is a mixture of loam and old spent Mushroom dung, and the plants should either be grown out of doors during summer in partially shaded situations, or in cold frames, where lights can be drawn off. As the corymbs of flowers are borne on the terminal points of the shoots, they should not be stopped later than the end of June or middle of July, or they will not have time to develop fine heads. The habit of the plant is naturally bushy, and it is better to allow it to assume its own natural form than to check and cramp it by stiff and unnatural training.

Linum trigynum.—This is but seldom met with in good condition, and yet, when well grown, it is one of the most useful of winter-blooming plants. There is a scarcity of really good yellow flowers, even in summer; therefore this *Linum* is doubly valuable, as it comes in at a season when gay flowers are most wanted. It should not be treated as an ordinary greenhouse plant; on the contrary, it requires special management to grow and bloom it successfully. It is useless attempting to grow it in a house among other plants, where it is subject to sudden atmospheric changes, as the growth is sure to be slow, and the leaves small and poor; a condition in which they become a prey to red spider. Anyone having an old plant or two of this *Linum* to start with, should at once place them in gentle moist heat, where they will soon afford a sufficient supply of cuttings. These should be taken off as soon as possible, and be inserted in cutting-pots, filled principally with rotten leaves, mixed with a small quantity of sand. Cuttings inserted in decomposed vegetable matter, such as leaf soil or peat, appear to emit roots much more freely than they do in anything

else; and, when rooted, they may be separated without injury. The soil best suited for them is a mixture of loam and peat, two-thirds of the former to one of the latter; but where peat cannot be readily obtained, the same quantity of leaf soil may be substituted. Most kinds of fast-growing plants delight in a loose, rich, porous soil, through which water can percolate freely, and this is of essential importance in growing this *Linum* successfully. After potting, it should be placed in gentle heat, and in a position where it can be kept moist by frequent syringing, or it will be liable to the attacks of red spider. To obviate this, it should be grown in a house or pit by itself, so as to receive the kind of treatment best suited to it. The most suitable place in which to grow it during the summer is a deep pit or frame that will allow room to hold sufficient leaves or old tan in which to plunge the pots; if either of these materials is in a state of gentle fermentation, so as to afford a slight bottom-heat, so much the better. It will be necessary to shade slightly for an hour or two during the hottest part of the day; but the shading should be removed early, and, after watering, the plants should be heavily syringed, so as to wet every leaf thoroughly, both upper and under surfaces; after which they should be shut up close. Treated in this way, they will grow freely, and be clothed with clean healthy foliage down to the pot, provided they are not plunged too thickly. By the end of September they should be placed in a light airy house, and be kept in a temperature of about 50°, in which they will open their flowers freely and continuously during the greater part of the winter.

J. SHEPPARD.

Woolverstone.

Azalea Buds Perishing.—It is a very common mistake for persons to suppose that, if Azaleas push young growth freely in the spring before blooming, it will have the effect of starving the incipient flowers, and thus prevent their opening. It is natural to all Azaleas, when in good strong healthy condition, more or less to make growth in this way, according to the nature of the variety; and, if the buds are plump and well-ripened in the autumn, it will in no way interfere with their flowering, unless in the case of young plants that make excessively lank strong growth. If at any time during the winter, or more particularly in the spring, after the young growth has begun to push, Azaleas are allowed to become dry at the roots, it will kill the buds. They will at no time stand so much drought as most other hard-wooded greenhouse plants—not even when comparatively dormant. Plants in good healthy condition are much more liable to suffer from an insufficiency of water than those having fewer leaves to support. I should recommend that Azaleas making strong growth should be kept warm a little longer in the autumn than the rest of the stock, so as to get their buds up larger and better ripened; as also not to allow the soil, during the winter and spring, to become quite so dry before water is given, as in the case of plants carrying a less quantity of leaves.—T. BAINES.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Sowing Primrose Seed.—In spite of what "A. D." says (see p. 124) I adhere to my advice of sowing Primrose seed as soon as it is ripe. I sowed some taken directly from the plants, about the end of June last in pans and kept it in a greenhouse ever since. Some of the seedlings are going to flower this season, and all are thriving young plants. Thus my method is a year in advance of that of "A. D." A few have already flowered.—FRANK MILES.

Camellia reticulata.—There is a remarkable specimen of this fine old *Camellia* now in bloom at Chiswick House. It was planted by Mr. Charles Edmunds in 1822, and he yet remains in charge of the place to see the plant gradually attaining greater dimensions and producing its numberless blossoms. The flowers are, as is well known, of large size and red marbled with white. It is a grand kind for cutting and is much in request at Marlborough House. The fine *Camellia*-house in the Prince of Wales's garden at Chiswick House is now and has been for many weeks past beautiful with abundance of flowers.—C.

Wintering Caladium Tubers.—A writer in the "Gartenflora" says he has been very successful in preserving his *Caladium* tubers. As soon as the leaves begin to die off in autumn, water is withheld from them, and the pots are left standing thus for two or three weeks, until all the leaves have quite withered away. The tubers are then taken out of the soil and trimmed, and all those of each sort, even if there are a dozen or more, are put together in a pot filled up with sand. The pots are then plunged over the rim into the hotbed of a propagating-house or Pine pit. In this way, the tubers keep as sound as could be wished; and when taken out in February, they already begin to sprout. They are then potted singly, and sunk in a hotbed to make their growth.—H.

Propagating Coprosma Baueriana variegata.—I can corroborate Mr. E. G. Ottewill's remarks on this subject (see p. 336). We put in about 600 cuttings of this *Coprosma* this spring in the way which he describes, and ninety per cent. of them have rooted. The chief points are, to have the plants in heat a few weeks before taking off the cuttings, to give them a brisk bottom-heat when put in, and not to attempt autumn propagation. We lift our plants in October, pot them, and put them in a close frame for a time until they have become established; then we winter them in a cool Peach-house or Vinery. The *Coprosma* will stand a little frost; it shows off its beautiful foliage best in the rainy days of autumn, therefore no one need be afraid of leaving it out until the regular bedding-out season has completely come to a close.—H. J. C., Grimston, Tadcaster.

THE FRUIT GARDEN.

SAUCERS OF SOIL IN STRAWBERRY FORCING.

As auxiliary feeders, saucers, or flats, are absolutely necessary in the pot culture of Strawberries when grown on shelves in hothouses, for the pots are always so crammed with roots, as they should be, that it is not possible with one watering a day to keep the plants supplied with sufficient moisture without the assistance of saucers. I like to keep the plants liberally supplied with water, and when needful with richer food; but frequent interference with them after the fruit is set is objectionable. For this reason I have always disliked using liquid manure, for fear of spilling it over the plants and fruits, thereby causing rust and disfigurement; and this season I have done without it entirely, and the plants have not, apparently missed it in the least. The flats which I use are of the ordinary size, but not for holding water, for I have them made to order with a hole in the bottom of each, and they are filled with light rich soil and put under the plants when they are first introduced into heat. To facilitate rooting through, I see that the crocks in the bottoms of the pots are clear, by chipping the hole a little larger with a piece of pointed iron. The pot is then set on the saucerful of soil, and I always find that the plants at once root into it, the saucer generally being well filled before the plants are in flower. No top-dressing is given, and this season, instead of using liquid manure, I mixed a little of Standen's concentrated bone dust among the soil for the saucers, with the best results. I would strongly recommend saucers of soil instead of saucers of water, which, except in careful hands, are apt to rot the roots. When soil is used the most active feeding roots are all in the saucer, which receives the water that runs through the pot; and it is always moist, even in the driest days, without ever getting sour, while there is no danger whatever, either from excessive drought or excessive moisture. Some may object to saucers of soil, seeing they have to be used from the beginning, otherwise their advantage is partly lost, and consequently prevent the pots being plunged in a bed of leaves at starting time, a practice very generally followed by Strawberry growers. My reply to this is, that I have ceased to believe in the utility of placing Strawberries in bottom-heat at the beginning, and afterwards lifting them out when they come into flower. The first thing which they do under such circumstances is to root through into the leaves; consequently, when the plants are moved these roots are sacrificed, while if they had had a saucer of soil beneath them they would have been saved—and that their assistance tells wonderfully in the end, in the size of the berries and general weight of the crop, I can attest from experience. I find that in about a fortnight, or less, the roots have generally got a good hold of the saucers and have frequently made several coils around them, that they are always exceptionally strong and active, and that the flower scapes are proportionately vigorous, and produce better fruit than they otherwise would have done.

J. S. W.

Peaches and Nectarines on East Walls.—We have two walls here covered with Peaches, Nectarines, and Apricots, one of which is a south wall, while the east wall, which is more than 100 yards in length and 11 feet in height, is entirely devoted to Peaches and Nectarines, but principally Peaches. The trees on both walls have borne well every year during these last five or six years, some seasons heavier than others; but, as a rule, the fruit has always set thickly enough to need thinning. It would, I think, be impossible to say that the trees on one wall were more fruitful than those on the other. As regards the east wall, there is perhaps one slight disadvantage with which we have to contend. I have noticed, especially after a wet autumn, that some parts of the young wood near the ground get cut by frost in winter; a circumstance doubtless owing to the wood being insufficiently ripened. This, however, occurs to so slight an extent that no great harm is done. The trees on the east wall are quite three weeks behind the others in coming into bloom, and from two to three weeks later in ripening their fruit, thus considerably prolonging the Peach season—an important advantage, while the fruit itself is fully equal to that on the south wall in size, colour, and flavour. In order to protect the blossoms, we use 14-inch coping boards, fastened to brackets with small hooks and eyelets, and, suspended from these, is wool netting. As soon as the fruit is fairly set, the coping and netting are removed, the brackets alone being left. At first, when the coping was put up, the boards were nailed permanently to the brackets, but this I found shaded too much of the tree; therefore I had it altered. I may add that from the presence of old Peach labels on the west wall, which is now covered with Plums and Pears, there is no doubt that at one time it was a Peach wall; and more than likely the change was made rather on account of getting fresh soil, than from any desired change in the aspect.—W. ORR, *Stow Hall, Norfolk.*

THE GARDEN IN THE HOUSE.

CHURCH DECORATION IN NEW YORK.

THERE can be no doubt that more cut flowers are used in New York than in any other city; and for church decoration on special occasions, such as Easter and Christmas, flowers are employed by all denominations. For wreaths, crosses, and other designs used at funerals, nothing but white flowers are employed, with the exception of Violets and yellow Rose buds. In a late number of THE GARDEN mention is made of the old-fashioned plan of making crosses on laths and wreaths on a bent stick or wire; the wire shapes, which cost but a trifle, are much better, and are used by all the florists in this country. Such shapes are backed up with tinfoil and filled with wet Moss; the flowers are wired on match sticks, which are sold in bundles of about a foot in length; these are cut to the required lengths. By this plan fewer flowers are consumed than would otherwise be the case, and the devices are made up in much less time than where laths or hoops are employed; and, should any tinfoil be visible, it is in character with the other decorations. The flowers employed at Easter for church decoration consist of white and red Camellias, and white and red Azaleas. Flag of Truce being one of the best of the white kinds, and being double and of good substance, lasts much longer than the single varieties. In addition to these are used Eucharis grandiflora, amazonica, and candida, Richardia æthiopica, Spiræa japonica, Deutzia gracilis, Passiflora princeps, perpetual Carnations, Tea Roses, and Violets. Of Orchids, Dendrobium nobile and Pierardi are often employed; of the latter I have cut shoots a yard in length and covered with flower, to form a wreath for the arm of a cross of flowers 6 feet in height, for a church in Philadelphia, and also for hanging round a lofty vase of flowers in Henry Ward Beecher's church, in Brooklyn. Mixed with Smilax, racemes of Passiflora princeps, and with Polypodium subauriculatum, Chysis bractescens, Angraecum sesquipedale, Cœlogyne cristata, different kinds of Cattleya, Lælia anceps, and Lycaste Skinneri, answer well. The most popular churches appear to use the most flowers, which are generally presented by members of the congregation; when such flowers are done with they are generally distributed among the different hospitals and other charitable institutions, to the inmates of which they prove most acceptable. Late on Saturday night, before Easter, the principal florists in Broadway may be seen busily preparing flowers, in different shapes, for the forthcoming Sunday—one may be found fitting up a 6 foot vase with white flowers, consisting of Camellias, Carnations, and Richardias; others preparing pyramids generally with a white ground and scarlet cross in the centre. In one church were vases full of Richardias and Lilium candidum, and white Azaleas in pots, but the plants were badly grown. In another church I saw a white cross, about 4 feet in height, with a dove above it, and vases of flowers on each side of it, and in the font was a large pyramid of flowers; in another, in addition to the cross and pyramid in the font, were baskets of flowers, chiefly Roses, on the communion table, and the chancel angles were filled with light foliage, such as that of Papyrus, among which were placed Lilies and Richardias. This was the lightest and most tasteful decoration I met with. These decorations for the most part looked too heavy, owing to the lavish way in which flowers were used without any relief from foliage. Easter Sunday was the third day of spring weather which we experienced after a long and severe winter; and, the snow was still a foot deep in gardens on the shady sides of the higher-lying streets; the sun shone brightly all day, and the air was moderately warm; in fact, seats in the squares were occupied by people without chance of being frozen to death, a calamity to which we have been liable for some months past; and, although the ice had not melted around the paddles of the ferry steamers, the rivers around the city were free from ice; but teams were still crossing the Hudson on the ice at Albany on the 2nd of April. JAMES TAPLIN.

South Amboy, New Jersey, U.S.A.

Small Vases for Flowers.—Charming arrangements of flowers can be made at this season with but few blooms and those not of expensive varieties. A few days since I arranged two little vases, or rather specimen-glasses, with the following:—In each I placed a single bloom of a double variety of white Azalea, some sprays of Deutzia gracilis, and three white Cyclamens, the whole being backed by a frond of Pteris tremula; two smaller fronds of this Fern were also placed in front, and bent down so as to droop gracefully. These little vases were arranged to match, and were for placing on a side table in the drawing-room. Many pretty floral groups can be effected with but few flowers if a little time and taste be employed in their arrangement. The Dielytra is a flower now coming into the market, and is well

adapted for the decoration of both large and small vases, as sprays can be obtained and cut off this plant of almost any size. This flower has the advantage, too, of being equally effective by either day or artificial light. As a hardy plant the *Pyracantha* is very useful for cut purposes; a spray of it, when placed amongst white flowers, such as Lily of the Valley, Deutzias, &c., with the addition of a little Fern, being extremely effective.—A. HASSARD.

The Night-scented Stock.—Amongst night-flowering and night-scented plants this is one of the best. Its flowers being of a dull colour, would probably be passed by unnoticed were it not for the delicious perfume which they emit as soon as the sun goes down, and which claim for them a place in balcony and window gardens, where their value is soon recognised. Plants with either scented leaves or flowers are great favourites here, but the prevailing fashion of adorning gardens, as if sight were the only sense to be appealed to, has driven out of cultivation many plants that once were held in high esteem; their unobtrusive hues would be lost amongst the glaring clouds of scarlet Geraniums and similar showy plants, whilst the foliage of many does not adapt them for the sub-tropical department. In balcony and window-boxes and borders, however, such plants are at home, and their fragrance is always welcome as it steals through the open window on the morning breeze or in the calm of a summer's evening. The Heliotrope, Stock, Balm of Gilead, Mignonette, Musk, *Aloysia citriodora*, and scented-leaf Geraniums are all thoroughly adapted for purposes such as these. It strikes freely by means of cuttings, and only requires the protection of a cold house or pit in winter. It will succeed in any good light soil, and will flower in great abundance with a small amount of attention.—JAMES GROOM, *Henham Hall*.

Flowers for the Sick.—A paragraph in the "Times" a few weeks ago, appealing for presents of flowers for the Home of Industry, Spitalfields, and Mildmay Park, seems to have given some benevolent people the excellent idea of collecting spring and other flowers, and sending them to the hospitals for the patients. Children are employed in their playtime by the Flower Mission to gather flowers in woods, fields, or gardens, as the case may be, and then the vicar of the parish sends them in hampers to the hospitals. Guy's has been the fortunate recipient of several hampers of flowers during the week, and the Home of Industry has sent one hundred bouquets, in flower-holders, tastefully surrounded by appropriate texts for the patients. If the clergy will take the matter up in earnest, the Flower Mission will be the means of cheering many a poor sufferer, and we hope all who have flowers to spare will send them to some one or more of the London hospitals. We assure our readers that a ward at Guy's, after the arrival of one of these hampers of flowers, was indeed a pleasant and cheering sight. The poor patients seemed to take a new lease of life from the freshness of the flowers, and bright, happy, contented, faces were to be seen on all sides after their advent. Will anybody, says the "British Medical Journal," refuse to aid the Flower Mission, or deny these poor sufferers, so cheaply purchased and yet so inestimably valued, a pleasure as a bunch of fresh, sweet, radiant flowers?

Latakia Tobacco.—The best Latakia Tobacco is cultivated in the districts of Diryoos and the Amamarah, situated in the most northern and elevated parts of the Ansariyeh Mountains nearest to Latakia, in Syria. Great care is bestowed upon its cultivation by the mountaineers, who, up to a short time ago, depended upon it for their chief support. The Tobacco harvest is in October in the mountains and earlier in the lower ranges. The leaves are gathered and strung upon strings of goat's hair, then left to dry in the shade, when they are hung to the rafters of the houses for fumigation or otherwise, and left thus till the tax-gatherer comes, when they are sold in loads of 100 or 150 strings. The best kind of Tobacco is known by the name of "abow riah," or father of scent, and of which a small quantity only is cultivated. That raised in the lower mountains is less valuable, and is called "skek el bent." The plant is the species called *Nicotiana rustica*, like that raised in China and most of Asia, and of which the leaves are shorter and broader than the *Nicotiana Tabacum*, or Virginian Tobacco. It has a most pleasant perfume, and, like the Havannah cigars, possesses probably but 2 per cent. of the poisonous volatile alkali called nicotine; whereas the Virginian Tobacco contains nearly 7 per cent. The greater part goes to Egypt and Turkey, and a small quantity to England. The cultivation of Latakia Tobacco has, in common with that of other Syrian varieties, lately received a severe check by the imposition of an import duty upon its entry into Egypt, and also by the establishment of the "Regie." The peasantry are relinquishing the cultivation of this article, and prefer sowing cereals in its place rather than continue its production under the adverse circumstances which now attend it.

GARDEN SONGSTERS.

FOR those who thoroughly enjoy the flower beauty of gay gardens and the shaded mystery of woods, many other closely associated charms possess nearly as great an interest as the aspects of the trees and flowers themselves. For instance; in early spring there are those charmingly fitful lights and shadows of gleamy April, and the murmur of brooklets swollen by its timely showers, and there are the gentle rustling sounds of the young fresh-budded branches as they are swayed by the spring breeze. But, above all, there is the song of birds of many kinds that fills the air with "gentle jargonings," as Coleridge so deftly named the bird concerts of our gardens, woods, and orchards—gentle jargonings, which must charm and soothe even those who do not notice (or think they do not notice) the harmonies that echo sweetly among the branches. We have had the merry twittering song of the wren, and the louder and more varied wild notes of the robin throughout the whole winter whenever an early gleam of sunshine or a mild still morning tempted them to warble forth their melodious matins; and then, in March, the light low refrains of other garden warblers commence, such as those of the Willow wren, a little innocent slaughtered remorselessly by gardeners as a pest, and deemed so on the authority of the amiable Gilbert White, who was, for once, mistaken, for the Willow wren is one of the gardener's best friends, being a most industrious destroyer of insects, more especially of aphides, as soon as they appear. The short but cheerful song of the chaffinch comes next, and never seems to weary the true lover of bird music, even by its incessant repetition, which seems to come like a pleasant and necessary refrain in the pauses of the concert. The short songs of many other little warblers then begin to play their part, while the continual twitter of others forms a running accompaniment that scarcely ceases till mid-day, to recommence, though with less briskness, towards sunset. Above the gentle din rise the wild wood-notes of the rich-voiced thrush, who sings out his delightful succession of detached notes or passages with a confidence and sweetness that induce many connoisseurs of the woodland opera to place him foremost among our native songsters. His rival, the blackbird, twirls out his quaint and resonant notes with equal power, and almost equal skill—he is the buffo of the woods. Instead of slaughtering these pretty vocalists, under pretence of their being more or less destructive to garden crops—and it must be admitted that the blackbird is very fond of Cherries—how much more interesting than the miserly saving of a little fruit that we can very well spare, would be the study of the sweet, wild music of these pretty singing birds. To be able to name each bird, even when unseen, by his song alone, is a pleasure none can know who have not tasted of it. Those, for instance, who go to the Italian Opera, ignorant of the names and characters of the singers, of the language in which they sing, and of the composers whose genius produce the music, enjoy but a vague and unsatisfactory impression of the performance. So in our woods, and gardens, and orchards, the enjoyment of the vernal bird-music is in corresponding proportion to our knowledge of the birds, their habits and their songs. In the foregoing list of tuneful songsters, the very greatest, and some holding brilliant places in the second rank, have not yet been referred to. The softly beautiful notes of the woodlark, sweet and low, have to an extent that none but "woodlark fanciers" can ever know or feel, their own peculiar charm; in comparison with which those of the soaring skylark, who only sings aloft, are, to a certain extent, noisy and coarse. There is the black-cap, too, whose notes, though less florid and varied, are almost as rich as those of the nightingale, and are sometimes mistaken for them; but when the nightingale himself arrives, generally about the 12th or 14th of April, all other bird-music is cast into the shade. His notes are more varied, more beautiful, more powerful, more brilliant, and present greater contrasts to each other than those of any other singing bird. Soft passages, that simulate the bubbling of running water through a narrow channel, are rapidly followed by others, sometimes repeated twenty or more times, brilliant and sonorous as trumpets sounding a victory. This is followed by trills of gradually rising brilliancy towards a glorious burst; and then a plaintive series of moaning sounds

HAPPY SECURITY.

succeed, rising in semitones, and culminating in an outburst of joy or grief, which leaves all other bird utterances far behind. Another series of the nightingale's notes comprises a succession of delicate hair-drawn sounds, finer and finer still, till they are like threads of glass, breaking at last into a brilliant cadence that I will not attempt to describe, because it is indescribable. Let every one who loves gardens, and with them one of their chief attractions, the music of our singing birds, study the song and the history of the nightingale; and the more they know of his habits, as well as of the details of his song, the more they will appreciate his annual spring visit—that is to say, if they have the luck to be located in a nightingale district, the distribution of his favours being exceedingly capricious; beautiful Devonshire being “out of his beat,” while tolerably bleak parts of Yorkshire are honoured by an annual attendance. Among things to be unlearned about the nightingale is much of the teaching of the poet, by whom it was thought that the glorious song was that of the female—the nightingale, as a song bird, being continually apostrophised as “she.” Another error to be got rid of is, the supposition that the nightingale only sings at night, while, in point of fact, the period of his most brilliant and lavish song is the brightest part of the spring day, from eight or nine till eleven in the morning. That he also sings at night, when the night is warm and still, and when there is a rising moon we all know, because he is so plainly heard in the calm silence, when no other bird is singing, but, even then, it is rather an evening song continued into the night, than, strictly speaking, a night song, for he never, except under some accidental excitement, sings in utter darkness. Enough has been said to show how much the enjoyment of a garden may be enhanced by cultivating a knowledge of our singing birds.

H. N. H.

Tea Culture in Italy.—I have just read a notice in THE GARDEN (see p. 336), that the Italian Government intends to introduce the cultivation of Tea into Sicily. It may interest some of your readers to hear of the attempts that are being made to cultivate it in Italy. A gentleman, who has extensive Tea plantations in the Himalayas, felt sure he could succeed with it in Italy, and, in the winter of 1873-74, imported a large quantity of Assam Tea-seed, part of which was sown near Viterbo, in February, 1874, and the young crop seems to be flourishing. The rest of the seed was given to me; but, unfortunately, did not reach me until towards the end of March, 1874, when the essential oil of the seed had undergone a considerable change, and the seeds seemed worthless. However, a few of them came up; they take about six months to germinate. My place is about 1,000 feet above the sea. The plants were small. When the cold weather set in, they stood the frosts of this exceptional winter, but were cut over by a bitter wind in January; they are now, however, shooting up from the roots. Among Teas, the Assam is the most delicate, and I do not think it will answer at this height. The same gentleman imported this last winter some of the Hybrid Tea-seed from the Himalayas—a cross between the Assam and the China. A large bag of it reached me in good condition; it is much hardier than the Assam. It was sown in February, and, I hope, may be a success.—FRANCIS NEVILLE REID, *Ravello, near Amalfi, South Italy.*

The Sycamore Tree.—In an interesting work on Palestine, written in French by Solomon Munk, occurs the following passage:—“The wild Fig trees or Sycamores were found in great numbers in the plain called Schefela. The Sycamore has a very strong trunk, and its horizontal branches, always green, extend afar. Its leaves are similar to those of the Mulberry; its fruit, which resembles Figs, has an insipid and not particularly agreeable taste. The wood, though light, is very durable; the Hebrews employed it in their buildings. The coffins of the Egyptian mummies were made of Sycamore wood, and have been preserved down to our own day. Ritter, quoting Clarke, mentions pictures on Sycamore wood found at the church of St. Anna at Siphori, in Galilee, and sent to Cambridge. These pictures, which are much older than the tenth century, are in good preservation, and are not worm-eaten. The Sycamore tree, from its vigorous nature, its branches so magnificently developed, and its perpetual verdure, is an exceedingly agreeable and convenient place of rendezvous. The Orientals climb up among the branches, as Zaccheus is said to have done. There they seat themselves, to smoke and chat. At present this tree appears to be growing rare in Palestine. Hasselquest did not see it, except on the coast near Jaffa.”

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Scarlet Runners, French Beans, Kale, Peas, &c.—A full crop of Scarlet Runners should now be sown. It does not do to let any considerable length of time elapse between this and the sowing already advised, as, if the first happens to suffer through frost, those now planted will succeed them without any loss of time. At the same time, put in some more Dwarf Beans. Green Curled and Cottagers' Kale should now be sown; these will come in for planting upon ground vacant from the early crops of Potatoes, Peas, &c. The Cottagers' Kale should be grown in every garden, large or small; it is as far superior to any other variety of the Kale tribe as a spring Cauliflower is to winter Broccoli. The seed is generally mixed; some of the plants coming up quite green, whilst others are tinged with purple. These latter only should be planted, as, both in flavour and texture, they are much superior to the green, and but little inferior to Brussels Sprouts. Go over the early sowings of Cauliflowers, Broccoli, Cabbages, and Brussels Sprouts. Remove all weeds from amongst them, and thin out the plants to about 4 inches apart every way. When these are allowed to remain crowded together, they get so weak and drawn that when planted out they are throughout the season behind such as have had sufficient room in the seed-bed; and, in the case of Brussels Sprouts, they never produce so good a crop. The plants that are thinned out may, if required, be planted out in a nursery-bed, where they should be 6 inches apart; at which distance they may stand for some time, and can be finally planted out later on, as more ground is cleared of other crops. Sow more Peas as succession crops, and also more Spinach upon any vacant spot.

Preparing Ground for Spring-sown Cabbages, Brussels Sprouts, &c.—Prepare the ground by digging it well, and by giving it a good dressing of manure for planting with the spring-sown Cabbages of different sorts and Brussels Sprouts, as it is important to get these in as soon as they are large enough to plant; especially the Brussels Sprouts, which become larger, and the produce is proportionately greater—if planted early. The ground for Celery should also be prepared at the present time. It is much better to have this in readiness before the time for planting has arrived, as it should be put in during showery weather if possible, which can be taken advantage of without delay when the ground has been made ready beforehand. The usual way of planting is in trenches, with from one to three rows in each. For the earliest, the three row system causes a saving of ground; but it is not suitable for withstanding the cold of winter, being more difficult to protect, more exposed to wet, and consequently more liable to rot. In wet heavy land, for winter crops, single rows are best; in such as is dry and tolerably light, two rows in a trench may be grown. Upon the number of rows it is intended to grow together will depend the width of the trenches. If three rows are planted the trench should be 4 feet 6 inches in width; for two rows a 3 feet trench is necessary; and, for a single row, one of 2 feet wide will suffice. The space between each trench will require to be proportionate to the width of the trench, so as to afford soil sufficient for earthing up, without coming so near the plants as to injure their roots—a mishap that often occurs in Celery growing. It is of importance to keep this in view, especially for the late or principal crop. Single rows, to stand through the winter, should have a space of 2½ feet between each trench, or, if 3 feet, all the better. For double rows allow 3½ feet between them; where three rows are to be planted 4 feet 6 inches will not be too much for them. In each case the trench should be formed by removing about 9 inches of the soil to the width required, and laying it up between each trench in the usual ridges. Then put in each trench 6 inches of good manure—such as has become thoroughly rotten is by many considered indispensable; but that which is half rotten is equally good, provided it does not contain too much straw. For dry light land, a mixture from the stables and cowshed is the best; the latter, being cooler, keeps the plants growing better in hot dry weather. Dig the manure in with 10 inches of the bottom soil of the trench, or a little more if there be sufficient depth without reaching that which is bad and unsuitable, and thoroughly incorporate the dung with the soil. Ground so prepared, some time beforehand, so as to get soaked with rain, is in a much better condition for planting than if only made ready immediately before the plants are put in. The ridges between the trenches, especially where double rows of Celery are grown, will answer for a row of Lettuce, which will be cleared off before the Celery requires earthing up. For this purpose, the middle of the ridges should be hollowed a little so as to hold the water which the Lettuce will need in dry weather; and here also manure-water will be of use, as the ridges cannot well be manured for the Lettuce.

Water Supply.—The greatest want in very many gardens is an adequate supply of water, especially in the kitchen garden, the

nature of the crops requiring very much moisture. This is more seriously felt on dry soils, yet it frequently happens that, at comparatively little cost, a copious supply might be drawn from higher ground; in which case it can frequently be made available, in the least costly manner as regards labour, by the use of a hose pipe and tap turned on amongst the growing crops. Where there is a considerable extent of vegetable ground, and where the walls are covered with Peaches and Nectarines—that must be plentifully watered, both overhead and at the roots—pumping is slow work, to say nothing of the frequent unsuitableness of water so obtained for application to any growing plant. Again, the means of conveying water from wells and tanks to the different crops is often not the best. The ordinary water-barrows sold by the general makers are the very worst used—mounted on miserably low wheels, they require three times the force to drag them that would suffice were they properly constructed and of a reasonable height. There is also very often deception as to the size, whether they be made of wood or galvanised iron. Such as are advertised to hold thirty gallons or so will generally, when measured, be found full when they contain eighteen or twenty. Where, as is the case in most gardens, large or small, the water has to be applied by hand, there is nothing that effects a greater saving in labour than a good water-barrow; the wheels should be 4 feet high, with a crank axle under the body of the barrow, which should be made of strong galvanised iron rivetted, made with a good large spout, and hung so as to enable the load being easily tipped over. It should hold from sixty to seventy gallons, with a handle in front fixed in the usual way to the irons that stand upright from the axle and on which the body is hung. Such a barrow, if properly constructed, and the wheels made to run easily, can be moved about on anything like level ground by one man, and with much greater ease than the low-wheeled inventions that will not hold one-third of the quantity. Those who have the good fortune to garden on deep alluvial soil with a cool bottom, or on moisture-holding peaty land, may think themselves well off in a dry season, but in far the greater number of gardens, even where everything possible in the shape of deep cultivation, liberal manuring, as well as mulching, is carried out, if water is not used freely, the crops will be small in quantity, and equally wanting in quality; but, where water is used without stint, the produce resulting from it amply repays the cost. One of the first considerations I should urge upon all amateurs who prefer an abundant supply of good, tender, wholesome vegetables to the tough, fibrous produce of dry, hardened soil, is to provide the best means for applying water.

Pits and Frames.—Melon-plants raised some time back should now be ready for planting out, for they should not be allowed to remain too long in the pots, where they are liable to be stunted. See that at first the bed is not too hot, or the roots may be burnt. Before the soil is put in, the old method of placing a sod 3 or 4 inches thick and about 2 feet square (with the Grassy side downwards) upon the bed, right under each of the small hills of soil in which the plants are to be put out, is a safe one to follow. This, unless the bed is much too hot, will prevent burning, and with a large bed is always an advisable precaution; for, even when the heat in the bed before it is soiled has subsided to 80° or so, a change to warm, mild weather will sometimes cause it to rise so as to injure the roots, if not prevented.

Peaches and Nectarines on Walls.—The fruit will now be set, and whatever protecting material has been used should be removed; but, where a moveable coping exists, this had better remain a little longer for fear of frost. A good washing with the syringe or garden-engine will be beneficial to them. Greenfly, which in most cases rarely fails to make its appearance, should be diligently sought for, not allowing more than two or three days to elapse without inspection. If they are allowed to get much hold of the young leaves, they quickly injure them, and are, in addition, much more difficult to destroy. They generally appear near the bottom of the trees first, and may easily be detected by their causing the leaves to curl up. When found, even in small numbers, syringe the infected

part with tobacco-water, not allowing a single leaf on which they exist to escape, or it will necessitate a repetition of the work.

Houses.—Vines that were started slowly at the end of February will, if all has gone on well with them, have set their fruit, and soon require thinning. The most approved practice with Grape growers is not to syringe at all after blooming, or only once, to remove the dead flowers; but with amateurs, especially those who have not had much experience with Vines, the case is somewhat different, and, if the syringe is not used, the probabilities are that the Vines will get over-run with red spider; and, although the use of the syringe has the effect of destroying the bloom, which undoubtedly adds so much to the appearance of the berries when ripe, nevertheless I should advise amateur Grape-growers to use the syringe daily until the fruit begins to colour. Syringe early in the afternoon, and close the house at the same time, whilst there is yet sun upon the glass. As to thinning the fruit, this should be attended to as soon as the berries get as large as small Peas; if they are allowed to attain a considerable size, it is so much taken out of the Vines for no purpose, and the work is much more difficult to perform. The quantity of fruit to be left should in all cases be determined by the strength and condition of the Vines; nothing can be worse than over-cropping; but no practice is more common. Bad as it is in the case of established Vines, it is worse with young ones. Vines that have been over-cropped whilst young seldom, if ever, gain their perfect strength, no matter

how well they may be subsequently treated. The size of the bunches should regulate their number; the powers of any Vine that is allowed to mature a dozen bunches of 2 lbs. each being quite as much taxed by their production as those of another Vine would be in ripening double the number of only half the weight. A stout Vine with a rod the length of an ordinary rafter, say 18 feet, will bear from 20 lbs. to 24 lbs. of Grapes, without being over-taxed; and, unless in exceptional cases, this is enough. In the case of open-air fruits, where they so often fail through adverse seasons, we are frequently tempted, when there is a chance, to take a much heavier crop than would be allowed to remain, could we depend upon having a reasonable quantity every year; but Vines under glass are subject to no such influences, and should never be taxed beyond what their strength can support without deterioration.

A Garden Songster (p. 369).

A Cottage Garden.—If I have no coaches and horses, I can at least hang a tracery of living leaves along my porch, so exquisitely

delicate that no sculpture can match it; if I have no conservatories with their wonders, yet the sun and I together can build up a tangled coppice of blooming things in my garden of which every tiny leaflet shall be a miracle. Nay, I may make my home, however small it may be, so complete in its simplicity, so fitted to its offices, so governed by neatness, so embowered by wealth of leaves and flowers, that no riches in the world can add to it without damaging its rural grace; and my gardeners—sunshine, frost, and flowers are their names—shall work for me with no crusty reluctance, but with an abandon and zeal that ask only gratitude for pay.—D. G. MITCHELL.

Flower Shows a Hundred Years ago.—In an article recently published in "Chambers's Journal," are the following advertisements on this subject, taken from the Ipswich journals of the years 1745, 1746, 1747, and 1748:—"This is to give notice that the annual show of Auriculas will be at the house of Mr. John Wards, at the White Lion, at Hadleigh, on Friday, the 27th instant, when all lovers of these pleasing productions of Nature will meet a hearty welcome and a kind reception from their humble servants—Peter Norman, Jacob Price, stewards." "On August 2, 1746. 'The sons of Flora will hold their annual feast at the Maid's Head, in St. Simon's, Norwich, on Wednesday, the 6th day of August next, when all gentlemen, who are admirers of the beauties of Nature, are desired to come and view the greatest number of new and well-blown Carnations that the year produces.'"

TREES AND SHRUBS.

MR. EDWIN LEES ON THE GLASTONBURY, OR "HOLY THORN."

THIS is considered by a writer in "Science Gossip" to be "a miraculous Thorn tree;" and as such it was no doubt represented by the monks of Glastonbury Abbey; for almost every monastery possessed some object intended to excite popular wonderment and veneration. The flowering twice a year, for which this Thorn is remarkable, is, however, a not very uncommon circumstance; for I have noticed it in the Eder, Dogwood, and other shrubs. Such a circumstance takes place every year among Apple and Pear Trees, and may be seen recorded in local newspapers as frequently as the stereotyped "big Gooseberry." The curious circumstance as to the Glastonbury Thorn was, that its second crop of flowers occurred so late in the year that they could be accredited to Christmas Eve. But it must be observed that when the style was altered by Act of Parliament, and eleven days omitted to correct the Calendar, the "Holy Thorn" did not recognise this alteration, and would not show expanded flowers until Old Christmas Day. This was some years since put to the test in Herefordshire, where there were, and still are, several "Holy Thorns;" and so determined were the inhabitants of the rural parishes to trust to the flowering of the Thorn rather than to the Calendar, that the clergymen of many country places felt obliged to hold services in their churches on Old Christmas Day. I have in various years received branches from "Holy Thorns," in January, having mostly unexpanded flowers that soon wither, and no fruit is produced from these secondary flowers. It is generally asserted that all these Christmas-flowering Thorns are the product of the original Glastonbury Thorn, which was destroyed by Puritanical hands during the civil commotions in Charles the First's time; but this I think very dubious. Quaint old Aubrey, in his "Natural Remarques in the County of Wilts" (1685), states that "in Parham Parke, in Suffolke (Mr. Boutele's), is a pretty ancient Thorne that blossoms like that at Glastonbury; the people flock thither to see it on Christmas Day." Aubrey further says that he was informed by Dr. Ezerel Tony, "that about Runnymarsh (Romney), in Kent, are Thornes naturally like that at Glastonbury." He mentions also that, "in the rode that leads from Worcester to Droitwiche, is a Blackthorn hedge at Clayn, half-a-mile long or more, that blossoms about Christmas Day, for a week or more together." This second flowering of trees and shrubs must, then, be considered a natural development, under special circumstances, which may or may not be continued, and certainly cannot be ensured to appear on a particular day, though often doing so, or near enough to the time for the credulous. The real Miracle, as affirmed by the monks of Glastonbury, was, that Joseph of Arimathea, after landing in Britain, paused upon Wearyall Hill, near Glastonbury, and planted his staff in the ground, whence sprung the wonderful Thorn that flowered every year at Christmas. That the tree really did arise from a Thorn staff stuck in the ground by some pious hand, if not the Scriptural Joseph, is not improbable; and this fact, noticed by the abbatial ecclesiastics, was a good thing to convert into the miraculous, while the double-flowering was luckily superadded. Hawthorn sticks will, in fact, vegetate, like Willow-branches; and Sir Thomas Dick Lauder, in his edition of Gilpin's "Forest Scenery," mentions the case of a Hawthorn stake, taken from a dead hedge, which, having one end sharpened and stuck in the ground, "spontaneously budded, put forth branches, and became a thriving tree." So I myself, some time since, brought home a tall denuded Hawthorn stick that I had picked up, which was stuck in the mould of the garden to prop up some plants; and this has rooted, put forth branches, and is now a flourishing tree of considerable height. It flowered abundantly last year; but, as yet, has produced no secondary inflorescence.

Green Hill Summit, Worcester.

EDWIN LEES, F.L.S.

Stuartia pentagynia.—This noble shrub is common in the mountains of Virginia and southward, and although long known as hardy in most of the Northern States, it is seldom seen in gardens. If a common name was wanted for this shrub, "Shell Flower" would be quite appropriate; for the half-opened buds resemble some of the two-valved shells with jagged edges, like the common scallops. The flowers are white, slightly tinged with cream-colour, the ends of the broad petals being scalloped, or what is termed jagged-edged. This species is a very sturdy shrub, 5 to 10 feet high, and when given plenty of room will be well furnished with branches from the ground upward. Its general habit of growth is to produce only a single stem, few or no suckers appearing from lateral roots. A specimen of this shrub planted ten years ago in my grounds has never been injured by cold, even during our severest winters, when

many of the kinds from a more northern climate have suffered severely.

Lindera Benzoin, also known by many other names, such as Spicebush, Wild Allspice, Feverbush, Benjaminbush, &c., is an interesting plant for the gardens of those who like a variety of shrubs. It belongs, however, to the Laurel family, although had it been an evergreen shrub this name would have no doubt been given it, as we have at least a dozen American shrubs called Laurels, not one of which is allied to the true Laurel. But our Lindera is a pretty shrub, growing 6 to 10 feet high, with large, dark green, obovate, oblong leaves 3 to 5 inches long. The flowers are quite small, yellow, and produced in spring, succeeded with bright red, oval berries, which are always ornamental. The leaves, bark, and wood emit an agreeable spicy odour when handled. It is a handsome, easily-cultivated shrub, seldom seen in gardens, although very abundant in the swamps of North America.

Clethra alnifolia, or Alder-leaved Clethra, is a beautiful late-blooming shrub, with spikes of small, white, fragrant flowers. In habit it is rather a slender shrub of 5 to 8 feet high, with few branches but numerous stems opening from the same root or stool, thereby forming a dense clump. It thrives in almost any soil or situation, and is as readily and safely transplanted as a Currant bush.

Andromeda Mariana, or as more commonly called, Staggers-bush, is a beautiful low-growing shrub, with deciduous leaves dropping late in autumn. It is very abundant in the Eastern States of North America in low grounds and thickets, where the plants are usually of quite slender growth and 3 or 4 feet high; but the habit is much improved when it grows singly in a garden. The leaves appear early in spring, and are of a light, glossy green, oval or oblong in form. The flowers appear a few weeks later in the season; they are pure white, a half inch or more in length, and of a tubular form, like the true Heaths, a family of plants to which all of our Andromedas belong.

Andromeda floribunda for House Decoration.—The flower-spikes of this plant are produced during the previous season, and the buds only wait for a few warm days to make them open. A branch cut off in winter, carried into a warm room, and the lower end placed in water, will soon unfold its flowers, giving one a handsome winter bouquet from the garden. We have some half-a-dozen or more species of the Andromedas which may be treated in a similar manner for producing flowers in winter.

Dirca palustris, or Leatherwood, is probably well known to every boy in the Northern border States, as its tough leathery bark is a natural source from whence good, tough strings can always be obtained when other depositories fail. But I am inclined to think few boys who have gathered Leatherwood bark for strings could tell after they became men the colour of the flowers or fruit of this shrub. Neither, however, are very showy or handsome, the former being small, of a pale yellow colour, produced in early spring before the leaves appear, succeeded by a reddish berry ripening late in summer. It is also rather a straggling-growing shrub, 5 or 6 feet high; but it is the only North American representative of the Daphne family.—Correspondent "Moore's Rural."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Redwood as Game Covert.—It is not well known that this noble Californian Conifer makes a valuable covert tree in Ireland, especially in sea-shore districts. It also forms good hedges at Bournemouth, and grows as much in one year as the Yew does in five.—JOHN BAIN.

White Camellias Out-of-doors.—There is now in bloom a fine double white Camellia in the garden of Dr. Chater, Tenby, from which eighty flowers have been cut this spring, and about forty still remain on the tree. The plant is about thirty years old, has never been under glass, and is growing vigorously in the open garden.—L.

Increasing the Redwood.—This tree is easily increased by means of cuttings. I have found that in making alterations, pieces of it cut off and stuck in as pegs strike root. One of the best trees in the College Botanic Gardens at Dublin was originally put in by a workman as a stake for a plant.—JOHN BAIN.

Yew not Poisonous to Deer.—It is generally imagined, and by clever observers too, that our sheep and goats eat Yew leaves with impunity. An old keeper in North Wales told me that the deer in P—— Park were very fond of browsing on the Yew trees that grew there; and that he had never met with an instance of Yew poisoning amongst them.—H. G. WATNEY.

Ivy on Beech Trees.—Allow me to inform "Salmoniceps" (see p. 311) that in the private grounds at Hackwood Park, near Basingstoke, there are (or were two-and-a-half years ago) several large Beeches with the main trunks and branches completely enveloped in Ivy to a height of quite 80 feet or more. Many of the trunks of these trees are 12 feet and upwards in circumference—with perhaps not a branch for 35 or 40 feet. Some few years ago, in the case of some of these trees, a quantity of Ivy was cut off, the stems of which near the ground were as thick as a man's leg. I have seen nearly a cart load of rubbish at the foot of the tree when the Ivy decayed and fell off.—H. J. C., Grimston Park, Tadcaster.

THE LIBRARY.

THE NARCISSUS: ITS HISTORY AND CULTURE.*

It must be pleasing to all lovers of hardy plants to see the various evidences of their growing popularity, among which must be included this valuable book. A dozen years ago very few grew or cared about these beautiful plants, and probably no publisher would have been found for a book on Daffodils; now we have most extensive collections of them, and amateurs will find all the information they require in this work. The plates, most of which are drawn from the life from plants in Mr. Barr's rich collection, are by Mr. Burbidge, who has executed them with great care and fidelity to nature. They represent all the species at present in cultivation in this country. A few plates of autumn-blooming species, one or two kinds not yet in cultivation having been taken from authentic dried specimens or drawings. Cultural and historical details are given. Mr. Baker's valuable review of the genus is reprinted, and a list is added of books and articles in periodicals treating of the Narcissus. The following extract concerning *Narcissus gracilis* will give an idea of the style of the work:

This is a very graceful plant, by no means common in gardens, although its grace, beauty, and grateful fragrance ought to make it

Narcissus calathinus.

a great favourite with amateur cultivators. The plant grows from a foot to nearly 2 feet in height, and generally flowers in May, or about the same time as the Poet's Narcissus, and bears from one to three flowered scapes, the latter being bright green, shining, and either cylindrical or slightly two-edged. In form and size the individual flowers are very similar to those of *N. poeticus*, but the whole flower is of a deep, clear, golden colour, changing to sulphur as the flower fades. The corona is cup-shaped or slightly campanulate, and a little plaited or crumpled around its margin. It is undoubtedly very nearly related to *N. poeticus*, and, as has already been suggested, may possibly be the result of a cross between the last-named species, or *N. biflorus* and one of the large-flowered Tazettas. The leaves, however, are very different to those of any of the supposed parents, and closely resemble those of *N. odorus*, or *N. Jonquilla*, both of which are very fragrant, and have yellow flowers, and it is not an improbable idea that it may have been raised between one of these and *N. poeticus* or its congener *N. biflorus*. The fact of its not being found in a wild state goes a long way in support of its being a garden hybrid. It is

* "The Narcissus: its History and Culture," with coloured plates and descriptions of all known species and principal varieties. By F. W. Burbidge. To which is added, by kind permission, a "Scientific Review of the Entire Genus." By J. G. Baker, F.L.S., of the Royal Herbarium, Kew. London: L. Reeve & Co., 5, Henrietta Street, Covent Garden.

one of the most deliciously fragrant species in the whole group, and its flowers are valuable for cutting, as they endure for fully a fortnight in a vase of pure water.—*N. tenuior* (the Slender Sulphur Narcissus) is a distinct and dwarf-growing form of the last, and is well figured in the "Botanical Magazine" (Curtis) t. 373. The bulbs are about the size of thrushes' eggs, and of a glistening greyish colour, not dark brown as in most of the other species and varieties. This peculiarity is well represented in the above named plate. It bears three or four leaves to a bulb, these being from 3 to 5 inches in length, rather slender, and of a dark shining green colour. The scape rarely exceeds a foot in height, and is generally two-flowered. The individual flowers are rather smaller than those of *N. gracilis* proper, being rarely more than an inch to an inch and a-quarter across. In colour they vary from lemon-yellow to nearly pure white, with a lemon-coloured cup. The figure in the "Botanical Magazine" was published in 1794, when the plant flowered in the garden of Mr. John Maddock at Walworth, who obtained bulbs of it from Holland under the name of *Narcissus flore Sulphureus Juncifolius*, and Curtis adds that it "appears to have been grown by the Dutch florists," and is "often double" in gardens. The last-mentioned double-flowered form is still one of the things hoped for amongst amateurs, and is probably lost to cultivation, unless like many other old-fashioned flowers it lingers still in some ancient country garden, unseen by our lynx-eyed modern florists. *N. gracilis* grows well in a warm richly-manured border, and when seen growing is easily distinguishable from *N. tenuior*, which is only about half the height of its congener, and blooms fully a month earlier under the same treatment. My specimens of *N. gracilis* were sent me by Mr. Harpur Crewe, and both white and lemon-tinted forms of the *N. tenuior* variety came from Mr. Barr's collection, in which I had an opportunity of seeing the plants in flower.

There are forty-eight plates in all, most of them replete with details which will greatly assist the student in determining his species. The colouring is not all that could be desired; but in all other respects the book is one we can heartily recommend. The figure above given is that of the rare and beautiful *Narcissus calathinus*. W. R.

Uses of Surface-stirring.—1. It destroys the weeds, which exhale the moisture of the soil with great rapidity. By placing a sash or a pane of glass upon growing weeds, the upper surface of their leaves will show the large amount of moisture they exhale, the evaporation of which is arrested by the glass, and which would be retained in the soil by the destruction of the weeds. 2. Ground thus often stirred, and loose, absorbs most of the water of showers, and retains it until much of it settles into the soil below; whereas, much of the water thus falling runs off rapidly from a hard surface. 3. The mellowed surface becomes more thoroughly warmed than a hard soil by the noon-day sun, and gives off that warmth more gradually during the night, and the plants are thus surrounded by an atmosphere warmer and of more uniform temperature, during the whole twenty-four hours. 4. But the greatest advantage of frequent stirring is, that the loosened soil acts as a mulching, arrests the ascent of the moisture by a capillary attraction, and keeps the soil in which the roots are acting moist. To secure this benefit of cultivating the land, it ought to be done just as soon as the soil becomes friable, after showers, whether there be any weeds to be eradicated or not. It is a mistake to suppose that the roots of plants are benefited by direct contact with air in the mellowed soil. Air is always injurious to them, and especially so if it be hot and dry. While the plants are growing their roots should not be exposed to the air, nor should the soil in which they grow be disturbed. The full benefit of cultivation may be secured if it be only deep enough to furnish a few inches of fine and loose soil upon the surface. It is often said that the loosened soil absorbs moisture from the atmosphere, and thus aids the growth of plants; but every one can see that the surface dries much more quickly for being stirred, and it is very clear that what little moisture is thus received in the night is very quickly evaporated, and cannot reach the roots, or the soil in which they work.

Apples and Pears in various Climates.—It is curious to observe the wide adaptation of the different sorts of the Pear, when compared with the Apple. A leading correspondent of THE GARDEN, in giving short, select lists of these two kinds of fruit, mentions Winter Nelis, Bartlett, Marie Louise, Capiaumont, Brown Beurré, and Louise Bonne of Jersey as the best among Pears, all of which are well known in this country; and Lord Suffield, Dumelow's Seedling, Alfriston, Cox's Orange Pippin, and Yorkshire Greening among Apples, most of which very few persons in this country have ever heard of. The same writer names Doyenné du Comice, Seckel, and Comte de Lamy, (which proved so fine with us) as among "representatives of the best Pears in existence."—"Cultivator."

THE FLOWER GARDEN.

PRUNING ROSES.

THE climbing Rose flowers upon the wood of the current year. The closer it is pruned the better it blooms at the latter end of the season, the more beautiful are the flowers, and the more numerous the shoots will be for pruning the following year. A Rose tree constantly long-pruned becomes deformed, and produces too many small flowers, whilst a close-pruned Rose tree presents a head like that of a Willow, and wears itself out quickly from the effect of the reflux of the sap, which induces the formation of suckers. By a combination of the two methods, the advantages of both may be secured, for each will neutralise the injurious effects of the other. With the Rose tree pruning to a medium length will be preferable to either the long or short system; but experience shows that in the majority of cases a combination of the two systems is still more advantageous. The following is our method of operation. The best-placed branches are subjected to long pruning, being cut to a length of from 8 inches to a foot, whilst the others are cut back or spurred to two eyes. Badly-placed shoots are cut clean out; young wood better situated will be encouraged to take their place. The shoots pruned on the long system will bloom early, whilst the shoots produced by the short-pruned wood will push out vigorous growths that will be covered with flowers later in the season. The following year this process is reversed; the long-pruned wood will now be short-pruned, whilst the shoots that were previously cut short are now long-pruned, according to their size, and every year this alternation takes place. Sometimes vegetation is retarded, and, should the long wood after their blooming show signs of withering, medium pruning in the middle of the summer will be beneficial. This treatment is somewhat analogous to that bestowed upon the double-bearing Raspberry. If at any time an over luxuriant branch is allowed to grow and bloom, which it will do profusely, if properly managed, it should be cut down, and the young shoots may be then used as cuttings. Under any circumstances, however, medium-sized shoots, especially of the Hybrid Perpetual or Moss varieties, of which the buds are well-formed, will, after having been pruned, blow during the first season, without becoming over luxuriant. I dislike summer pruning. As soon as a Rose has shed its blossoms it is best to leave the shoots uncut, as the terminal eyes are the most floriferous, and any pruning tends to exhaust the tree. This floriferous disposition of the top eyes shows that amongst the more productive kinds—Chromatella, for example—the Rose cultivator should choose his scions from the upper extremity, and immediately below the flowers when possible. These luxuriant branches should be kept back, by a pinching at spring-time, to a length of 12 inches, and the laterals will become floriferous; it is upon these that the pruning of the following year should take place. The best time for pruning Roses is April; autumn pruning induces buds to burst too soon, which are thus rendered liable to injury from spring frosts. By operating whilst the sap is rising the dormant eyes, which have not yet commenced to push, are acted upon. As to non-climbing kinds of Roses, it is better to leave them alone, or to long-prune a certain number of branches, without which they will become over-crowded. The branches should be thinned, by removing some of the superfluous wood. The latter will produce shoots for long-pruning the following year, and the former will be covered with flowers. So soon as the blossoms have fallen they should be again cut back to dormant eyes, or to a well-placed branch. Nothing else need be done to the others, except to restrain them, by pinching-in too luxuriant growths.

Troyes.

C. BALTET.

FRUITING OF THE HARDY PALM IN THE UNITED STATES.

(CHAMÆROPS FORTUNEL.)

WE noticed an article in a recent number of THE GARDEN in regard to this Palm, which you call hardy, as it probably is in the climate of England. We enclose you a photograph of a fine plant of this Palm, which fruited in our collection at Boston last year (1874). You cannot, however, from this form an exact idea of its beauty, as the colour of the fruit enhances this in a high degree. The fruits or berries, which are just the size of small wild Grapes, are of a dark blue colour, covered with a thin coating or skin, which is also dark blue, but entirely covered with a dense rich bloom, like that of the purple Plum or finest black Grape. A cluster of the fruit, exhibited by us two weeks ago before the Massachusetts Horticultural Society, was thought to be an immense bunch of small Grapes. About fifteen years ago we received several small plants of this Palm from London, and two of them were kept for specimens. These have been grown in pots or tubs during the whole period, and the plants are now 8 feet high, with a stem 8 to 10

inches in diameter. They have been grown out of doors every year, from April to November; kept under the stage of the greenhouse when small, but latterly in a cold house in winter. Two years ago one of these Palms produced a panicle of splendid yellow flowers, showing it to be a male plant. Last spring (1874), soon after they were put out of doors, in April, both of the plants began to show their flowers, which were watched with much interest, in the hope that one of them might be the female, as the flowers of the one were much smaller and less showy than those of the other. This proved to be the case. They stood within 10 feet of each other, and without artificial fertilisation the female plant produced three immense compound panicles of berries, 18 inches broad and 70 long, numbering, as near as we could estimate, 3,000. These were fully grown before the plants were removed to the house in November, and might have been gathered, though they had not attained their beautiful deep blue colour; but they were so very ornamental that we allowed them to remain until January, when they were cut off, as the berries began to fall. In your climate the hardiness of this Palm must render it one of the most valuable in cultivation; for, in addition to its robust growth and broad, handsome, deep green foliage, the great masses of deep golden-yellow flowers, lasting, as they did, three to four weeks, are highly ornamental, and the fruit in all stages, particularly after it attains its rich blue colour, is very beautiful. Even in our climate the plants have been allowed to stand in the open air long after every greenhouse plant was safely housed and all kinds of open air vegetation killed by heavy frosts, the thermometer falling as low as 22°, and this without the least browning of the leaves in the case of the Palm. Young plants are wintered in a frame as safely as a Holly or Laurustinus, which, in our cold climate, are killed by the first frost that sends the thermometer down to zero, and we have had ten days of it in January this year. As regards the difference that is said to exist (see p. 517) between the male and female plants, we have not seen it in our two plants. The stem of the male is a little stouter or thicker than that of the female; but, beyond this, no difference is perceptible. Both of our plants are of equal height and breadth, and, in fact, are as handsome a pair of this species of Palm as could be desired; the tubs are 2½ feet in diameter. In our climate, as a lawn plant, for vases, or for ornamental tubs, this Palm possesses the highest merit, for it can be placed out-of-doors a month earlier and kept out a month later than any other Palm, Agave, or tender Yucca—all good plants for such uses. Has this Palm fruited in England?

Boston, Mass.

C. M. HOVEY.

PACHYPHYTUM BRACTEOSUM AND KLEINIA REPENS.

THE first of these is a perfect gem among succulents, its rich creamy colour and neat habit rendering it a conspicuous and most effective object in a mixed bed of its class. Some dislike succulents for bedding purposes; but judiciously mixed beds of them have really a fine appearance. Without the Pachyphytum, however, and its indispensable associate, the Kleinia, with its blue glaucous foliage, the effect is imperfect. Unfortunately, the Pachyphytum can only be increased slowly, and requires to be planted thickly, so that a hundred plants go but a little way. We have been busy propagating it for several years, and have no great stock yet. One way is to top the plants in autumn, potting each top singly in a thumb pot. They are sure to strike on a dry shelf, near the glass, in an intermediate temperature, and make fine plants by spring. The old stumps will break in two or three places during the winter, and in spring the offsets may be detached, and make neat, though small, plants by bedding time. The second way of increasing it is by leaves. These may be detached at any time, taking care to cut them off with just a heel of bark adhering to each, then lay them in a ring, as close as they will lie, round the inside of a flower-pot saucer half filled with soil, the heels of the leaves all pointing inwards, with the base of each just resting on the soil, but not covered. They will want little or no water, and after a considerable time a cluster of little plants will be seen forming at the base of each leaf; when these are large enough to handle, they should be detached, potted, and treated like the others. The percentage of leaves which damp off before the young plants form will be in proportion to the care given in watering, &c. We have a number of young plants coming on in this way at present. The third way is by seed; but the difficulty is to get it. Last October a small plant showed a flower-spike, and as soon as it was observed I had it taken up from the bed, potted it, and put it on the back shelf of our winter Cucumber-house; it flowered, and was fertilised with a camel's-hair pencil in December, and the few pods which it bore ripened seed, which was sown in January in a shallow saucer, and we have now a capital batch of

seedlings up and doing well. The *Kleinia repens* is an equally valuable acquisition, owing to its colour. It is a capital plant for edging, massing, or mixing, and is easily propagated, for every bit will root freely if simply inserted in the soil. We keep it down to a uniform level during the summer by simply topping the longest shoots and sticking them in the ground, and in this way thicken the bed and increase our stock at the same time. Mixed beds of succulents should never be planted where they cannot be planted thickly, almost touching each other in fact. When, therefore, there is not enough for a large bed confine them in a small one rather than intermix them with ordinary bedding plants with which they ill associate. One of our most admired beds last year consisted of four small circles entirely filled with succulents. In the centre was a good plant of *Sempervivum canariense* or *c. giganteum*, and around these *Echeveria metallica*, *E. glauca major*, *Roechea falcata*, and others. *Aeonium arboreum variegatum*, *Kleinia gigantea* and *repens*, *Pachyphytum*, *Sempervivum tabulæforme*, and others, all planted compactly together, and tapering down to a margin of *Sedum luridum* or *hispanicum*; between these and the Grass was a line of *Echeveria secunda glauca*. These beds were filled in May, producing an effect at once, and lasted till November, when the plants were taken up. To produce the desired effect the beds should be well filled with soil, rounded well up in the centre in an easy curve, and be made quite full at the Grass margin, otherwise the outside row of plants will appear as if sunk and lost. Plant also close to the Grass edge, so that when the edging shears are run round the bed the Grass and succulents will meet. If the lawn is kept closely mown with the machine such a bed will then appear like a gem set in a green velvet groundwork. If any gaps or soil are seen the illusion is destroyed at once. I have the edgings of the beds clipped with sheep-shears to avoid cutting the leaves of the plants. A succulent bed is nothing if not kept perfectly trim and neat.

J. S. W.

THE WASHINGTON LILY.

AFTER reading Mr. Bull's letter (see p. 343), I would venture to suggest that the names of the different varieties of *Lilium Washingtonianum* should be considered an open question till these Lilies have again bloomed this season. The history of their introduction I imagine to be this. In March, 1872, Mr. Bull sold bulbs of *L. Washingtonianum* at a guinea each. These, I believe, belonged to the first importation. On the 9th of January, 1873, Messrs. Backhouse & Son sold at Messrs. Stevens's, Lily bulbs, which were thus described:—" *Lilium* (new species?), California, allied to *L. Washingtonianum*; grows 6 to 10 feet high, and bears as many as forty flowers on the spike, very fragrant; regarded by the collector as either a distinct variety of *L. Washingtonianum*, or a new species altogether; very scarce." On the 18th December, 1873, Mr. Bull sold, at Messrs. Stevens's, bulbs with this description:—" *L. purpureum*, this beautiful new Lily has been discovered and sent from Humboldt County, California. The collector writes that it is the finest of all the Californian Lilies, and describes it as producing about twelve flowers on a stem, which are very fragrant. The petals, on opening, are of a beautiful purplish satin colour, changing to a delicate purple-lilac. This importation has been received by overland express, and the bulbs are in splendid condition." When buying these bulbs, I believed them to resemble it closely; if not to be identical with the new species *Washingtonianum* imported by Messrs. Backhouse; and now, on examining the young growth of the two, I think this opinion will prove correct. There is this difficulty about the original *L. Washingtonianum*. It was always said to be a most beautiful Lily. This would not be justified by those first imported, but would by *Washingtonianum purpureum* and by *Washingtonianum* new species; though I doubt their attaining the height described at Messrs. Backhouse's sale. With us last year the two last were dwarfer, and had smaller foliage than the first *L. Washingtonianum*; and now, though the bulbs are well established, this character continues. I should not be surprised if it turns out that we have as many varieties of *L. Washingtonianum* as of *L. canadense*.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

An Open Air Conservatory.—Having two rooms with bay windows, and a smaller room with a flat window between them, there is a plot of ground thoroughly commanded by three windows; I propose making this into a sort of open air conservatory, as it faces west, and the sun here is very powerful; we should have a number of rock-work pockets, but only one tier. Some of these pockets would have fixtures in the shape of very dwarf evergreens, such as *Skimmia japonica*, the dwarfiest *Retinosporas*, *Sedums*, *Gaultheria procumbens*, &c., but most would have a space kept open by an empty flower pot, into which plants in pots,

which which had been brought into bloom elsewhere, would be placed and renewed as required; by this I should hope that, especially in spring, a space might be kept furnished, as in a conservatory with beautiful flowers, where they would be thoroughly seen from the house, and that the protection of the stove would prevent their being much damaged by wind, rain, or sun. Any experience in this direction, given in your columns, will be thankfully received.

—GEORGE WILSON, Heatherbank, Weybridge.

Hardiness of the Japan Primrose (*Primula japonica*).—

I find this Primrose to be perfectly hardy in North Yorkshire, where it has been exposed to one of the most severe winters which we have had since its introduction into England. I thought last January, after the snow has disappeared, that all my plants of it were annihilated, for the foliage had disappeared, and nothing was to be seen but the heart. New foliage is, however, now appearing, and flower-stems are beginning to show themselves. Plants in pots, which have had the protection of a cold frame, are of course in a more forward state; and my strong seedlings potted in September look much better than two-year-old plants, and promise to bloom first. For pot plants intended for windows, strong seedling plants, potted in September in a compost of turfy loam mixed with a liberal proportion of leaf mould and rotten dung, are suitable. I use long narrow pots, 5 inches diameter at the top and 11 inches deep, such as are used for Hyacinths. It is a plant which requires a deep pot, in order that its long, thick, fleshy roots may grow downwards. It requires a great quantity of water, and should be supported with frequent doses of liquid manure. If grown out of doors, the flower-stems should be supported by small flower sticks, in order to protect them from injury from wind and rains.—H. T.

The Old Parma Violet.—Gradually, and almost imperceptibly, the old and thoroughly appreciated Parma Violet is, says the "Revue Horticole," disappearing from amongst the cultivated varieties; and its place is being usurped by another kind, which certainly has the same name and appearance, but none of the qualities that rendered the genuine variety such a favourite flower. In the true Violet of this name are combined a delicate blue colour which is most charming to the eye, and a remarkably sweet scent, so peculiarly its own that it can only be described as the scent of the Parma Violet. Now-a-days, that which is sold, even in large quantities, under the name in the markets, has a somewhat fuller flower and a deeper shade of blue. The leaf also is slightly smaller, and more regularly orbicular; but the flower has a singularly disagreeable scent, and, therefore, can never compensate us for the loss of one of the most sweet-scented of all Violets.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Parsons's White Mignonette.—I am cultivating this very valuable addition to our gardens, and am pleased to state that in whiteness, size of flowers and spike, and fragrance it is worthy of all praise.—W. S.

Chamaepeuce diacantha.—"N. H. P." (see p. 345) probably fails with this through treating it too well. Here it is naturalised, sows itself, and comes up freely. Occasionally I take a head of seed and sow it broadcast anywhere, and it takes very good care of itself.—H. N. ELLACOMBE, *Bitton Vicarage*.

Variegated Arabis and Aubrietia purpurea.—These planted as edgings to spring beds plant for plant are now singularly beautiful. Another mixture worth recommending is *Thymus citriodorus aureus* and double red Daisies. A third, a bed of Belvoir Yellow Wallflower with an undergrowth or carpet of *Myosotis dissitiflora*. The latter and variegated Arabis also make a very good mixture.—N. H. P.

Pretty Hyacinth Bed.—One of the prettiest flower-beds that could be designed is made up of Baron Van Tuyll for centre or back, then a line of white Grand Vainqueur, followed by a row of Robert Steiger, the whole being edged with the pretty though common Golden Feverfew. Taking notes of such effective displays when the plants are in flower is the best way for amateurs to arrange for next year's planting.—ROBERT McKELLAR, *Abney Hall*.

Variegated Plants.—Extremely beautiful is the variegated Comfrey (*Symphytum officinale variegatum*) which has large leaves exquisitely margined and streaked with cream colour. What makes a plant so beautiful if regularly variegated is that attention is thereby directed to the form and outline of each individual leaf. A Clover which I found in the fields is now a mass of creamy-white and rich green, and one of the most striking hardy plants I have ever seen.—FRANK MILES, *Bingham, Notts*.

American Cowslips in the North of England.—*Dodecatheon splendendum*, *Meadia*, *elegans* (syn. *giganteum*), and *album*, I have all in one little bed with an east aspect and light soil, and they all thrive well and flower more effectively the longer they are left undisturbed. The first named was long favoured with a place in a cold frame, but it does better in the open ground, and is now in flower, beating, in this respect, by a long way, all its companions. *D. Jeffrayanum* thrives with me under different treatment, namely, in a shady and cool position in ordinary garden, but somewhat moist, soil.—G. F., *Henham*.

Fritillaria uniflora.—This is a beautiful spring-blooming bulbous plant, the leaves of which resemble those of some of the Snowdrops. The blooms rise about 6 inches above the ground, and are composed of six white bluish-tinted petals, with a most delicious fragrance. It flowers freely during March, April, and the beginning of May. I lately saw a number of these plants doing well in rich open soil in a somewhat shaded position; and, although surrounded with many Dog's-tooth Violets and other pretty spring flowers, I thought this compared favourably with any of them.—J. MUR.

Old Writers on Daffodils.—I observe that "Hill" is uniformly called "Hale" in the article (see p. 343) on double Daffodils.—JAMES BRITTEN.

GARDENING FOR THE WEEK.

Flower Garden and Pleasure Ground.

It is yet unsafe to take bedding stocks from under glass, unless protection of some kind is in readiness to be applied whenever there is any appearance of danger from frost. Continue, however, to give abundance of air whenever the weather is at all favourable, in order to harden and prepare Geraniums and other bedding plants for being planted out soon after the middle of this month. The hardy Fernery or rock garden will now be interesting, and will require its share of attention. Slugs and snails are frequently troublesome in this department at the present season, and take refuge during the day under blocks and stones, where they should be searched for and destroyed. Continue to frequently roll gravel walks soon after rain, also lawns and Grass verges. If the lawn is in any degree mossy the present is a suitable time to endeavour to improve it; this may generally be done by encouraging, as much as possible, the growth of the finer Grasses, by means of slight surface dressings of some enriching material, such as finely-sifted soil, lime, wood ashes, and soot. But in situations under trees and elsewhere where Grass cannot be induced to grow satisfactorily, Moss should be encouraged rather than otherwise; for, although it is apt to become somewhat brown during dry weather, it nevertheless quickly regains its green hue after a shower or two. Attend carefully to recently transplanted trees and shrubs; and, if the weather continues dry, water frequently at the roots, as well as overhead, by means of the garden-engine, on the evenings of bright sunny days. Doubtless all necessary arrangements regarding the furnishing of beds, borders, baskets, and vases were decided upon last autumn, and the materials required for effectually filling them selected; but, should a deficiency in any instance be apprehended, it is not yet too late to remedy the omission; the stock of such species of plants as Verbenas, Lobelias, Petunias, Coleus, Iresines, and the Alternantheras, of various sorts, may still be increased. In the arrangement of the various species of decorative plants in the flower garden, it may hardly, perhaps, be necessary to caution the planter against the too free use of the primary or bright colours, or to say that undue breadths of scarlet and yellow are seldom consistent with tasteful arrangement, unless judiciously toned down by the moderate use of plants of remarkable and ornamental foliage, in order to prevent any approach to a glaring effect; while anything like monotony or flatness should be prevented, or may be greatly relieved, by the judicious introduction of statuary of some kind, such as vases, fountains, &c., together with standard and pyramidal plants of various sorts, as single specimens, in centres of beds, and upon the turf. The latter may consist of such species as Fuchsias, Pelargoniums, Cytisus, Acer Negundo variegatum, &c.; while trained to wire arches, and similar devices, many ornamental climbing plants may with advantage be introduced, such as the various varieties of the beautiful new Clematises, and some of the stronger growing tuberous-rooted Tropæolums. The flowers of many of the Clematises are exceedingly beautiful, some of them being of a colour greatly required in the flower garden, and they may be used with advantage as bedding plants, merely requiring, in fact, attention in the way of regulating and pegging down the shoots. The style of planting flower beds, known as carpet bedding, may not, perhaps, meet with universal approbation, but the system may, nevertheless, be to some extent introduced to most flower gardens with advantage, were it for no other reason than the circumstance of its calling into use many of our most interesting and curious looking hardy plants, remarkable for their dwarf and compact habit of growth and colour of foliage, such as the following, viz., *Achillea umbellata*, *Ajuga reptans rubra*, *Antennaria tomentosa*, *Arabis lucida variegata*, *Artemisia frigidi*, *Aubrietia deltoidea variegata*, *Cerastium tomentosum*, *Leucophyton Browni*, *Oxalis corniculata rubra*, *Santolina incana*, many of the Saxifrages, the new Golden-margined Thymes, &c., together with many suitable succulent plants, hardy as well as tender, including *Echeverias*, *Sempervivums*, *Crassulas*, *Dasyliirions*, *Cotyledon pulverulentum*, *Fourcroya longæva*, *Kleinia ficoides*, *Pachyphytum bracteatum*, *Agaves* of various sorts, &c. These, with the beautifully coloured *Alternantheras*, the *Coleuses*, the Golden Feather *Pyrethrum*, and the *Stellaria graminea aurea*, &c., form some of the principal material required for this style of embellishment, which, when tolerably well done, seldom fails to attract attention, and frequently commands admiration. There is also another style of planting, generally known as sub-tropical, which frequently produces a pleasing effect. The plants used for this purpose principally consist of tender species, such as the *Abutilons*, *Acanthuses*, *Amarantuses*, various sorts of *Cannas*, *Chamæpence Cassabonæ*, *Datura fastuosa*, *Echeveria metallica*, *Erythrina crista Galli* or the Coral tree, *Ferdinanda eminens*, *Ferula*

gigantea, *Melanthus major*, *Nicotiana glauca*, *wigandioides*, &c., *Phormium tenax*, the various sorts of *Ricinus* or Castor Oil plants, *Solanum marginatum*, *robustum*, and *Warcewiczii*, *Wigandia caracasana*, the Striped Japanese Maize, &c., most of which it would be unadvisable to plant out earlier than the first week in June, as their magnificently large leaves are liable to be injured by slight frosts and boisterous winds, which the ordinary occupants of the flower garden generally endure with impunity; and this circumstance renders sub-tropical plants unsuited, as a rule, for situations much exposed to high winds.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Indoor Fruit Department.

Vines.—In some places Geraniums and other bedding plants are grown on Vine borders to their detriment, though their presence in such situations is not wholly inimical to the welfare of the Vines, inasmuch as in hot dry seasons the shade which they afford protects the Vine roots. In planting bedding plants on Vine borders, it is not advisable to carry them up too near the house, as in that case the Vine roots might be interfered with. The distance to be left clear should be regulated by the quantity of roots near the surface and the width of the border. Six feet of a border 12 feet wide may be planted with impunity with Geraniums, Calceolarias, and other somewhat deep-rooting plants; and when more than that distance is wanted to be covered with plants, such surface-rooting varieties as Verbenas and Lobelias should be used. I have known a few inches of rich soil to be laid on the surface of the Vine border at bedding-out time for planting in, and removed again when done with in autumn. In that case, the Vine soil was in no way injured. In all cases the top soil should be well enriched with manure before planting, so as to keep the roots near the surface. Early Grapes in general will now be colouring. The borders will, therefore, not need watering before the fruit becomes nearly ripe, as much water at the root after that time does not improve the flavour. A temperature of 65° at night, and 10° or 15° degrees more during the hottest part of the day, finishes Grapes well; and a circulation of fresh air with these day heats, gives a higher and more perfect flavour than would be obtainable in a confined atmosphere. Sun heat is considered to be much more advantageous to the finishing of Grapes than fire heat; but, no doubt, the abundance of fresh air which sun heat admits of being given, is quite as favourable for the proper ripening of Grapes as the solar rays.

Pines.—With longer days and more sun-heat there is not so much danger of over-damping now in the case of Pine plants, as there was when these were not obtainable. A moist atmosphere is of much benefit in the case of a strong heat being given. When the plants are syringed overhead in the morning, careful ventilation is needed to prevent the leaves from getting burnt with the sun before they are quite dry, but once a day is quite often enough to syringe even in the summer time, and the best time for this operation is when the ventilators are finally closed. The moisture then supplied is generally sufficient to last till the following morning. Leave nothing undone which will in any way assist the development of successional plants. Watering at the roots, but at the same time guarding against saturation, must be particularly attended to. Experience soon teaches the happy medium between these two extremes. May and June are months of which every Pine grower should make the most, as subsequent months should be depended on more for maturing growth than making it. In order to have Pines ripe every week in the year the succession should be regulated so as to have one or two showing fruit every other week. A few Smooth Cayennes or Jamaicas must be got into fruit now, or there will be a gap in the supply in autumn when the Queens are consumed.—J. MUIR.

Kitchen Garden.

On the morning of the 22nd inst. we had here 7° of frost, but, everything being dry, the damage done is trifling. It is astonishing how effective a very slight protection is as a shield against spring frosts. An old fishing net, supported on sticks over beds of early vegetables, such as Cauliflowers, Cabbages, Carrots, Lettuces, &c., a couple of feet or so above them, helps to forward the crop through our cold springs wonderfully, slight and inexpensive as such a covering is. Some time ago I was noticing the difference presented by four rows of Beck's Gem Peas, sown side by side on the same day; two of these rows had been covered with the ordinary wire Pea guards, whilst the others were altogether unprotected, and there was a very marked difference in favour of those to whom this shelter had been extended. There cannot, I think, be a doubt that early crops of vegetables may be much forwarded by the simple expedient of netting them over. This acts in two ways; it checks radiation and, at the same time, breaks the force of cold currents of air, and thus raises the temperature round the plants growing immediately beneath it. The first lot of Scarlet Runners should be planted with-

out delay; this is one of the most useful vegetables grown, and should be planted in quantity. A row or two may be planted on a warm site to come in early; whilst the main crop should be grown on deep, rich land, and allowed plenty of room between the rows, but the height of the sticks will in some measure form a guide; as, by pinching and stopping, Beans can be grown to any height between 3 and 7 feet; and, if tall sticks are used, which are, on the whole, the most profitable, 6 feet between the rows will not be too much. It is desirable also to have the drills or trenches a little below the natural surface, especially on dry soils, to facilitate watering. Any or all of the following Peas, may be sown as desired for succession crops:—G. F. Wilson, Veitch's Perfection, Huntingdonian, and Maclean's Best of All. Cabbages now turning in may have the leaves drawn together and a string of matting or roffea tied loosely round to hold them together and induce them to heart more quickly.—E. HOBDAV, *Ramsey Abbey*.

NOTES OF THE WEEK.

— AMONG the most interesting of all plants exhibited at Regent's Park on Wednesday last, were profusely-flowered examples of the well-known deep blue coloured *Lithospermum fruticosum*. As generally grown, this is a shrubby hardy plant, which spreads in dense mat-like masses over dry banks or rock-work. The plants here alluded to, however, were trained in the form of little standards, and, grown in this manner in small pots, we know of no more beautiful blue-flowered plant for indoor decorative purposes.

— A FINE large-flowered form of the rosy North American Lady's-slipper *Cypripedium (humile) acaule* is now blooming in Mr. Bull's collection at Chelsea. The beauty of this graceful plant consists in its great pouch-shaped lip, which is of a remarkably delicate rosy-flesh colour, and very curiously folded in front. *Goodyera pubescens*, also from the North American woods, is likewise very effective, its ovate cushion-like leaves being of a soft velvety green, delicately netted and embroidered with silvery veins. Both are plants of easy culture, and succeed in a humid greenhouse temperature, and also in the open air.

— ON April 16, a meeting of botanists from various parts of Scotland (says "Nature") was held at Perth, to hear the report of the committee (appointed at the Fungus Show held in Aberdeen last autumn) to organise a Scottish Cryptogamic Society. A constitution was adopted, and office-bearers were elected for the present year, the President being Sir T. Moncreiffe of Moncreiffe, Bart.; Vice-president, Professor Dickie, Aberdeen; Secretary, Dr. Buchanan White, F.L.S. It is intended to have a show of Cryptogamic plants, especially of Fungi, every year in various districts of Scotland in rotation, and the show for this year is to be in Perth in the last week in September, when it is expected that a very large number of specimens will be exhibited.

— THE Royal Exotic Nursery at Chelsea is just now well worth a visit, early-flowering Orchids and stove and greenhouse plants being in excellent condition. In one of the stoves are forty large plants of *Anthurium Scherzerianum* in full flower, some of them bearing from twenty to thirty spathes each. Among *Phalænopsis* the following are in bloom—viz., *P. grandiflora*, *P. amabilis*, *P. Ludemanniana amethystina*, *P. L. ochracea*, and the exquisite *P. Parishii*, one of the most delicate and exquisite of all Orchids. In the cool houses many kinds of *Odontoglossum* are in great beauty, and among them the soft rosy *O. vexillarium*, bearing ten fine flowers on two spikes; several others, also, show strong flower-stems. *O. Alexandræ* is represented by several beautiful varieties, including *O. Alexandræ Veitchii*, which promises to surpass the beautiful *O. Andersonianum* in profuse purplish-brown markings. Early *Rhododendrons*, *Clematises*, *Hydrangeas*, and other decorative plants, are also now finely in bloom.

— ONE of the most attractive objects in Hyde Park just now is a large plant, or rather small tree, of *Magnolia Soulangeana*, profusely covered with its erect bell-shaped flowers, of wax-like consistence and pearly whiteness, except the outsides of the perianth segments, which are suffused with purple. This tree is about 12 feet in height, and about the same in diameter. The branches droop gracefully, and the erect, sweetly-perfumed flowers which terminate the extremity of every branchlet, give a candelabrum-like appearance to the whole plant which grows on the undulating strip of fresh green turf a few yards from Albert Gate.

— APPLICATIONS for space in the British section of the Philadelphia International Exhibition of 1876 are numerous, and of a satisfactory character. In consequence, however, of recent arrangements, by which the time for space required is extended, it will be possible for the British Executive to receive applications from intending exhibitors, addressed to 5, Craig's Court, Charing Cross, up to the 15th of May inclusive.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

APRIL 28TH.

AMONGST the chief attractions of this exhibition were the Roses in pots, which were well flowered and unusually fragrant. There were also interesting groups of new and rare plants, and the Metropolitan Floral Society took advantage of the occasion to hold its Auricula show in the conservatory. The more remarkable of the usual exhibits included a fine collection of foliage and flowering plants from the Royal Exotic Nursery, Chelsea. Among these we noticed various *Dracenas* and *Crotons*, including *C. Lord Cairns* and *C. Disraeli*, two very distinct kinds, sent to Messrs. Veitch by Mr. Macaffee, of Sydney; also a fine panful of the new and distinct bluish-tinted *Echeveria Peacockii*, one of the best of the genus for pot culture; *Nepenthes intermedia*, a garden hybrid, of compact habit, with bright green foliage, and pitchers resembling those of *N. Rafflesiana*; the same firm also sent a panful of the purplish-fruited *Anthurium (Violaceum) margaritaceum*; *Cypripedium Schlummi* var. *album*, and various other Orchids. Mr. Bull had several new *Dracenas*, including the rosy and white-striped *D. Hendersoni*, *D. rubella* (a kind with lance-shaped bronze-green leaves, margined with bright rosy-crimson), *D. elegantissima*, and the dense-habited *D. candida* (a miniature form of *D. regina*), and various Orchids; a plant of the white drooping-flowered *Crinum brachynema*, with eight flowers on a scape; and three singular *Arads* in bloom, consisting of *Dracontium asperum*, a kind having dark brown cowl-shaped spathes; *Amorphophallus campanulatus*, with upright bell-shaped blotched spathes; and the trifoliate *Typhonium Brownii*, with glossy leaves, and large bowl-shaped spathes of a rich maroon tint inside and glossy green without. Mr. B. S. Williams furnished an effective group of new Orchids, Palms, Ferns, Cycads, and succulents; among these we noticed *Gloneria jasminiflora*, a plant having opposite leathery leaves of the tenderest green, and clusters of tubular pure white flowers, borne on the tips of the axillary branchlets; a small plant of *Magnolia Hennii*, bearing two large fragrant flowers, white within and deep rich purple without. The same collection also contained various Ferns and Orchids, the latter consisting of several well-flowered *Dendrobes* and *Odontoglossums*. Messrs. Rollisson staged a well-grown group of Palms, Ferns, Orchids, and other plants, among which we noticed the handsome *Gymnogramma decomposita*, four elegant and vigorous little specimens of *Cocos Weddelliana*, the rich bronze-leaved *Dracena stricta*, *Maranta Makoyana*, and two healthy plants of *Vanda suavis*; also a vigorous and finely-coloured specimen of the beautiful *Croton Wisemanii*. Messrs. Cutbush had a well-arranged miscellaneous group of Palms, *Spiræas*, *Azaleas*, and other spring decorative plants.

Stove and Greenhouse Plants.—In Mr. Ward's collection of these was a plant of *Odontoglossum Pescatorei*, bearing two branched spikes, on which were seventy-three flowers; also the large-spathed *Anthurium Scherzerianum* (figured in THE GARDEN at p. 317), and which, on this occasion, bore six fine spathes and one unopened bud; likewise one large *Anthurium*, bearing twenty-five spathes; and good plants of the crimson and white *Clerodendron Balfourii*, the rich orange-flowered *Ixora salicifolia*, the fragrant white-flowered *Rhynchospermum jasminoides*, some well-grown Cape Heaths, and other plants. Fine standard *Azaleas* came from Mr. Turner, of Slough, among which we remarked *Comtesse de Flandres*, a kind with large elegantly crisped rosy-lilac flowers; *Reine des Fleurs*, with salmon white-edged flowers, the upper segment being spotted with crimson; *Duc de Nassau*, one of the best of rosy-flowered varieties; and *Cedo Nulli*, a good lilac-purple, one dense mass of bloom. Messrs. Lane & Son had half-a-dozen conical-shaped plants, one of which, *Roi d'Hollande* had large smooth flowers of a remarkably vivid scarlet. Mr. J. James, gardener to W. F. Watson, Esq., of Isleworth, had six well-bloomed little *Azaleas*, among which were *Roi des Doubles*, a kind having rosy-lilac compact rosette-like flowers; and *Mars*, a small-flowered vivid scarlet variety. Messrs. Dobson also had six well-bloomed plants, as had likewise Messrs. Cutbush and Wheeler. Mr. Carmichael, gardener to H. Tugwell, Esq., Crowe Hall, exhibited half-a-dozen hybrid *Azaleas*, the stock of which has, we believe, been purchased by Mr. B. S. Williams. One of these, named *William Carmichael*, is a hybrid between the small purple-flowered *A. amoena* and *Flag of Truce*, a double white-flowered kind; Mrs. Carmichael is a hybrid between *Amoena* and *Stella*. These, as well as the others, were free-blooming decorative plants, which promise to prove very valuable, and are quite distinct. A large-flowered hybrid *Rhododendron*, named *Countess of Dudley*, came from Mr. C. Turner. It was 4 or 5 feet in height, and bore twenty or thirty trusses, each flower of which was nearly as large as that of *Lilium longiflorum*, but shorter in the tube. Its foliage is fresh and glossy, and its snowy wax-like flowers have a scent like that of a wild Rose. The same exhibitor also staged a large-flowered white or rosy-striped *Azalea*, named *Apollo*, a profuse-blooming kind. Messrs. Lane had a dozen well-bloomed *Rhododendrons*, among which was the well-known *R. fastuosum*, still one of the best of the double-flowered kind. Well-bloomed collections of *Cinerarias* came from Messrs. Dobson and Mr. James. Mr. Barnes, gardener to A. Chancellor, Esq., The Retreat, Richmond, furnished six well-flowered pyramidal specimens of *Parson's White-flowered Mignonette*, a very fragrant and good kind. Roses were shown in excellent condition by Mr. Turner, among whose plants were examples of *La France* and *Le Mont Blanc*, the latter a delicate sulphur-flowered Tea-scented variety; the rich crimson-flowered *Duke of Edinburgh*, *Madame Thérèse Levet*, and *Paul Verdier*, a full rosy-purple Rose with fine foliage. Mr. W. Paul had half-a-dozen small

plants of his new Hybrid Perpetual Rose, named Peach Blossom, a fine kind, delicate in colour, and deliciously scented. Mr. John Walker, nurseryman, Thame, Oxon, had two superb stands of Maréchal Niel, the flowers of which were perfect in form, and of the most exquisite wax-like substance; also a stand of Gloire de Dijon and Maréchal Niel mixed.

Hardy Herbaceous Plants.—Of these Mr. Parker, of Tooting, had a good collection, in which were the yellow-flowered *Corydalis* (*Fumaria*) *nobilis*, *Dielytra* (*Dicentra*) *spectabilis* *alba*, the pearly-white Wood Lily *Trillium grandiflorum*, *Scilla amœna*, a dense mass of the purest cerulean blue, a potful of the rich crimson golden-eyed *Primula elatior* Early Admirable; also well-grown examples of the dense snowy-flowered *Iberis linifolia*, and the golden-rayed *Doronicum austriacum*, *Scilla italica*, and a good specimen of the deeper purplish-blue variety of *Scilla nutans*. In the same collection were the blue and purple-flowered *Orobis cyaneus*, the double-flowered Marsh Marigold (*Caltha palustris* fl. pl.), and *Primula elatior* Golden Plover, masses of bright orange-yellow flowers. Associated with these were also a small plant of the Fennel-leaved Peony (*Pæonia tenuifolia* fl. pl.), bearing four rich-fringed petalled double flowers of the richest crimson-scarlet; a dense little encrusted Saxifrage, named *Saxifraga aretioides primulina*, bearing slender stems, 2 or 3 inches in height, and having primrose flowers; *Anemone nemorosa rubra* fl. pl., with semi-double whitish flowers, tinted with flesh colour, each as large as a shilling; a dense tufted purple-flowered Violet, named *Viola Delabordei*, with small heart-shaped leaves, and well worth a place in select collections in which hardy spring flowers are grown; a pan of the Three-leaved Cuckoo-flower, *Cardamine trifoliata*, furnished with dense clusters of milk-white flowers, on stems an inch or two above the fresh carpet formed by its glossy leaves; and a plant of the dwarf double Marsh Marigold, bearing rosette blooms as large as a shilling, and of the most brilliant orange-yellow. Mr. G. Wheeler also had a miscellaneous collection of hardy early spring flowers in pots. A collection of Alpine and show Auriculas, in excellent condition, came from Mr. Turner. Amongst these the following received certificates, viz.:—*Gertrude Knight* (Turner) a black green-edged variety; *Iron Duke* (Turner), an alpine with velvety black margin, suffused with purple; *National* (Turner), a fine flower of the deepest velvety purple, with sulphur-tinted paste. Messrs. Carter & Co. exhibited their beautiful new *Coleus*, named *Duchess of Edinburgh*, and also a basket densely carpeted with a variegated form of the common Musk, named *Mimulus moschatus variegatus*. Mr. J. Douglas, Loxford, contributed a fine basket of that best of all Primroses, *Primula cortusoides amœna*, with tall scapes of rosy-purple white-eyed flowers. The white and lilac varieties were also shown for comparison. Mr. J. Chambers sent six plants of a *Cineraria*-leaved *Primula*, named *P. mollis*, said to be a native of Bhotan; the flowers in size and colour resemble those of a pale-flowered *P. japonica*, and are borne on loose hairy scapes. Messrs. E. G. Henderson had a charming group of miscellaneous decorative plants, among which were dense headed little trained standard plants of the lovely blue-flowered *Lithospermum fruticosum*, and two baskets of *Bellis aucubæfolia*, including a white quill-flowered variety, named *Flower of Spring*. In this collection were also some graceful little fresh green plants of *Sonchus pinnatifidus*, and the still more slender-leaved *S. elegantissimus*, both of which are graceful plants for table decoration. In the same group were one or two distinct zonal and variegated bedding *Pelargoniums* and some distinct and effective double *Cinerarias*.

The following New or Rare Plants received Certificates:

Odontoglossum Roezlii album (Williams).—An effective variety of a well-known and beautiful Orchid, perfectly white, except a blotch of lemon-yellow at the base of the lip. Mr. W. Bull likewise had a plant of this variety, to which a certificate was also awarded.

Metroxylon filare (Williams).—A distinct and effective decorative Palm, with pinnate leaflets of the freshest green tint.

Gloneria jasminoides (Williams).—A distinct and very beautiful decorative plant of shrubby habit, having opposite leaves, oblong in form and of leathery texture. Its flowers are borne in clusters at the apices of axillary branchlets, and are pure white in colour, tubular in form, and slightly downy.

Tillandsia musaica (Bull).—A Bromeliaceous plant from New Granada, having slightly pale green foliage transversely marked with deep green. Its flowers are rich orange-yellow on yellow bracteate spikes. A very effective and permanent stove foliage plant.

Crinum brachynema (Bull).—A fine Amaryllidaceous plant, bearing pure white deliciously-fragrant bell-shaped flowers on cylindrical scapes from 2 to 3 feet in height. Well worth growing for cut flowers, or as a stove decorative plant.

Typhonium Brownii (Bull).—A trifoliate *Arad*, bearing large bowl-shaped spathe of a rich maroon colour inside and shining green outside. An interesting stove curiosity.

Dracæna insignis (Bull).—A very effective and distinct addition to a well-known group of stove foliage plants. It has lance-shaped foliage of a bronze-like brown, margined with deep rosy-crimson.

D. candida (Bull).—A dwarf and compact-habited plant of the *D. regina* section, but much neater in habit, and its colour is better at an earlier stage of its growth. It grows about 15 inches in height, and has fresh green foliage, margined or striped with white or creamy-yellow.

D. elegantissima (Bull).—Similar to the last in habit, but furnished with long slender bronze-tinted leaves, margined with bright rosy or crimson. This and the two last are well worth culture as plants for table decoration.

Thrinax nobilis (Bull).—This is one of the most beautiful of all the species. It has bright green fan-shaped foliage, which does not appear to be affected with the rust which destroys the beauty of *T. gracilis* and other kinds. It is a stove Palm of easy culture.

Rhynchosperma robusta (Williams).—A graceful pinnate-leaved Palm, *Wallichia*-like in habit, having fresh green leaflets borne on glaucous or downy petioles.

Croton Disraeli (Veitch).—A distinct and effective plant, furnished with broad three-lobed or halberd-shaped leaves of a glossy green, and spotted with golden-yellow. One of the most interesting and remarkable of all the *Crotons* now in cultivation.

C. tortile (Veitch).—A strong-growing plant, with green bronze-tinted

leaves, spotted with crimson, the leaves being curiously twisted or contracted like a corkscrew.

Dracæna hybrida (Veitch).—A fine new hybrid raised in the Royal Exotic Nursery, and described by us last week.

Croton appendiculatum (Veitch).—A singular green-leaved variety, the blade of which in places is reduced nearly to the mid-rib, and again enlarged towards the apex. The ends of the leaves hang down in a most peculiar manner.

Dracæna elegantissima (Veitch).—A slender crimson-margined variety, likely to be much used for table and stove decoration.

Bertolonia Van Houttei (Van Houtte, Ghent).—A dwarf-habited plant, with oblong carmine veins and delicate markings on a velvety ground-work of the richest and freshest green colour imaginable.

B. Mirandæ (Van Houtte, Ghent).—Similar to the last, but the colouring on the velvet-cushion-like surface of the leaves is confined to the minute dots or spots of rosy-carmine. Both are very beautiful, and will be useful additions to a warm humid stove.

Freezia Leichtliniana (Colchester Bulb Company).—A bulbous-rooted plant, from the Cape, resembling a *Babiana* in habit of growth, and furnished with linear hairy leaves. Its flowers are of a pale sulphur-yellow, marked with rich orange in the throat, and are similar in shape to those of a *Tuberose*; while their perfume resembles that of a *Primrose* or *Auricula*.

Sonchus elegantissimus (E. G. Henderson).—One of the most graceful and fairy-like of all fresh green-tinted decorative plants. Specimens a foot high will be very useful for table decoration; and, as it grows freely, it ought to become very popular for this purpose, as well as for stove or greenhouse decoration.

NOTES AND QUESTIONS—VARIOUS.

Large Flowered Dog's-tooth Violet (*Erythronium giganteum*).—I saw this at Belvoir the other day. It is more like a little Lily than a Dog's-tooth Violet. It is of a yellowish colour, very beautiful, and should be in every garden.—FRANK MILES.

The Peruvian Daffodil (*Ismene Amancaes*).—This, until re-introduced by us last season, and again this, was quite lost sight of. The plant from which I send flowers has been grown in a warm house, but we had it in blossom here last season out of doors much later. It may be readily forced.—THE NEW PLANT AND BULB COMPANY, Colchester. [The flowers sent were deep yellow and sweet-scented.]

Keeping Down Weeds.—This is the best season for checking the growth of weeds by means of constant hoeing. Groundsel, Chickweed, and the annual Meadow-grass, should be hand-gathered if in flower or seed, and either burned directly or mixed with quicklime. The little extra time required to kill weeds now will be saved long before the autumn.—R. P. B.

Chamæpeuce diacantha from Seed.—Your correspondent "N. H. P." must have patience with his seed of this plant, as it usually comes up in successive crops. I have generally found that a few started early, but the bulk of the sowing will remain quiet for weeks or months. But little heat is requisite.—W. THOMPSON, Ipswich.

White Broccoli.—Will some of your correspondents inform me what varieties of the above I may grow to ensure a supply of good white Cauliflower-like heads. Out of half-a-dozen varieties sown last year five out of every six have turned out to be of the Brimstone class.—AMATEUR SUBSCRIBER.

Best Time for Planting Potatoes.—I cannot agree with "J. S. W." that the end of April is soon enough to finish planting the main crops of Potatoes. It may do in cold soils and situations, but to make it apply to all parts of the kingdom is quite a different thing. The end of March is considered late for planting in this neighbourhood.—J. GROOM, Henham Hall, Suffolk.

I think, in our eagerness to be first every season, we gardeners have upset, by early planting, the custom of our fathers. I remember, in my youth, which was passed in the north-west of England, in the cotton manufacturing districts, that the mill hands used always to reckon on putting in their crop of Potatoes at Whitsuntide, which is usually far on in May or early in June. The station master, when I came here, was a Yorkshireman, and never, under any circumstances, did he put in any Potatoes for his main crop before May, yet he always had good crops, and a less percentage of disease than any of his neighbours. Had we not better go back to the old path?—N. H. P.

Canker in Young Apple Trees.—Canker has made its appearance here in spots on the stems of our young trees, and spreads gradually around the stems, eventually destroying the whole of the upper portion. The trees in question are standards, four years old, and are growing in heavy soil on limestone and gravel. What, therefore, in the opinion of your correspondents, is the cause of the canker, and what remedy would they recommend?—A. B.

Double Cinerarias from Seed.—I have throughout the late winter carefully tended my stock of what I supposed were true plants of double Cinerarias, in the expectation of having something worth looking at in the spring, and my disappointment may be imagined when I found that, instead of a good display of double blooms, I only obtained worthless single flowers—a result most vexatious after the care bestowed on them. Have others been equally unfortunate?—T. B. WILSON, Claydon Park, Winslow. [Messrs. E. G. Henderson showed a collection of these Cinerarias on Wednesday last, raised from seeds, and among them were flowers as full and fine as those of the best double Daisies.]

Writing on Zinc Labels.—Few labels are better than those made of zinc provided their oily surfaces are carefully cleaned with fine emery paper before writing upon them. Their permanency, however, may be very much extended by warming the label after it is written, and rubbing it over with a paraffine candle. This protection to the writing I have found to be very effective, but I intend to make a further experiment in the way of coating the warm label with hard spirit varnish, as the photographers serve their negatives. Perhaps some of your correspondents may have tried this experiment, and can give us their experience.—W. H. C. CULLINGFORD, Phillimore Gardens, Kensington.

Darlingtonia californica.—The finest specimen of this singular plant in Britain is doubtless that at Glasnevin, whose flowering for the first time we had occasion to notice somewhere about this time last year, it is just now showing flower again. It was this plant which furnished the splendidly-developed pitchers with which the President of the Royal Society illustrated his lecture, delivered before the British Association last autumn at Belfast. Their dimensions will be probably considerably increased this season, as the plant has been transferred from the pot in which it was growing to a pan of large dimensions, where it will have a larger feeding ground for its roots.—"Irish Farmers' Gazette."

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

A ROCK-GARDEN ON MAY-DAY.

ROCK-GARDENS are now becoming so general all over the country, and so much interest is felt in the development of this kind of gardening, that any remarks upon the appearance presented by Alpine plants at different seasons are likely to prove serviceable. Throughout the year, but more particularly after the month of February, many of the rock-work compartments present each day some new and interesting feature, and it is pleasing to observe the numbers of amateurs who may be constantly seen taking notes of the plants as they come into flower in the Edinburgh and other public gardens which happen to possess facilities for their cultivation. In order to render as much assistance as possible to those who are seeking for information on this subject, I am endeavouring to draw up a list of all the more interesting early bulbous and Alpine plants as they come into bloom, giving at the same time their dates of flowering. Such a list, I have reason to believe, will be useful to those who desire successions of Alpine plants in bloom, but who have no opportunity of bringing their own observation to bear upon the flowering of any really valuable collection. During the early months of the year the principal interest in the rock garden arises from the flowering of the various dwarf bulbous plants, of which numerous varieties are now to be seen in cultivation in all parts of the country. Such plants are usually grown in borders, and, as a general rule, many of them succumb to this treatment before the next flowering season comes round. On the other hand, in rock garden compartments they are easily preserved, either by being left to themselves, or by having a few dwarf annuals dibbled on the surface of the compartment over the bulbs as soon as is practicable after the flowering is over and the roots are matured. The bulbs of these plants are generally at such a depth that no injury can befall them. Although I reserve a department of the rock garden entirely for Monocotyledons or dwarf bulbous plants, still a few of these here and there assist in maintaining the general display of bloom until the ordinary Dicotyledonous group begins to flower. The rock-garden at Edinburgh contains 8,000 stone compartments, each varying from 3 to 18 inches in diameter, and, in consequence of the number of spaces, many duplicates of choice plants flowering at the same time are placed at uniform distances apart, and at different elevations. The large extent of surface permits a wide separation of the bulbous plants that are here cultivated; and the use, therefore, of shallow-rooted annuals are not so much required. On the first of May, no fewer than two hundred and fifty species and varieties of dwarf herbaceous and Alpine plants were counted in bloom. By far the most attractive plants at the present time are the numerous varieties of the Ericaceous group; and, just now, we have about sixty plants dispersed throughout the rock-garden of the *Menziesia empetrifolia*, wholly covered with bloom, each plant having an hemispherical shape, and varying from 3 to 5 feet in circumference. A similar number of plants of the *Menziesia coerulea* are also in full flower, varying from 30 inches to 3 feet in circumference. About twenty plants of the *Bryanthus erectus* are also in beautiful flowering condition, varying from 20 inches to 2 feet in circumference, the whole surface of the plants being literally a mass of bloom. *Andromeda fastigiata* and *A. tetragona* are also in full flower, as well as *Erica hybernica alba* and *E. h. striata coccinea*, *Rhododendron Chamæcistus*, *Dryas Drummondii*, and *Azalea procumbens*, with numerous other species of this interesting dwarf shrubby section. At the present time, the *Aubrietias*, of which endless varieties are covered with flowers—the plants hanging down the sides of the rock-garden—are remarkably beautiful. Many varieties of *Primula* are now in perfection, *P. vulgaris rubra*, *P. ciliata purpurata*, *P. japonica*, and *P. denticulata purpurea* being the most attractive. Various other plants, such as the *Dondia Epipactis*, *Pulsatilla bracteata*, *Trillium*

grandiflorum, *Erythronium giganteum*, *Adonis vernalis*, *Schivereckia podolica*, *Hutchinsia alpina*, with numerous other varieties of the herbaceous section, are all freely interspersed over the rock-garden, adding much to its beauty, the colours being so arranged as to give a pleasing effect to the whole. The interest, too, is long kept up by having many of the plants in different exposures, an arrangement which renders it possible to extend their blooming period. JAMES M'NAB.

Royal Botanic Gardens, Edinburgh.

THE WASHINGTON LILY.

SEEING that, by an inadvertence, the wrong Lily had been figured in THE GARDEN for *L. Washingtonianum*, I directed attention to that fact (see p. 343), and evidently it is well that I did so, for Mr. Wilson's remarks (see p. 373) clearly show that there is much confusion respecting it. Mr. Wilson says, "There is this difficulty about the original *L. Washingtonianum*, it was always said to be a most beautiful Lily; this would not be justified by those first imported." Those first imported, however, were only original in the sense that they had not been introduced to this country before, for it is a distinct species, and all collectors and travellers agree that, as seen in its habitat, it is very beautiful. Here it certainly has disappointed us; and the only supposition I can arrive at is that it requires free scope for root action, and must be thoroughly established before it does much good. *Lilium purpureum*, although its bulbs are naturally small, and quite unlike the loosely-scaled ones of *L. Washingtonianum*, produces its flowers very freely when only a few inches high. The bulbs which I imported of *L. Washingtonianum* were found on the Sierra Nevada, in California, 6,000 to 7,000 feet above the level of the sea, where the ground is covered in winter with from 15 to 20 feet of snow. On the other hand, those of *L. purpureum* were found 400 or 500 miles distant, in Humboldt County, on the lowlands near Eel River, where the climate may be said to be that of perpetual spring; and, from the size and shape of its bulb, its habitat, growth, and mode of flowering, it appears to be distinct from *L. Washingtonianum*. I can scarcely understand how Mr. Wilson can call the latter "*Washingtonianum* new species," inasmuch as the *Washingtonianum* of the Sierra Nevada is of itself a species. "In conclusion," says Mr. Wilson, "I should not be surprised if it turns out that we have as many varieties of *L. Washingtonianum* as of *L. canadense*." Of course it is difficult to say what may be discovered; but no traveller or collector that has seen it flowering has yet informed us that it does vary, all those yet met with being of the normal type. It would, however, be extremely interesting if distinct varieties could be found. WILLIAM BULL.

Chusan Palm (*Chamærops Fortunei*).—Permit me to inform Mr. C. M. Hovey (p. 372) that this has fruited here for the past three years, and that it is perfectly hardy there can be no manner of doubt, as it has withstood, without the slightest protection, all kinds of weather since 1867. There are here two plants, 9 feet high and 8 feet through, clothed to the ground with leaves, some of which are 2 feet in width, whilst the stems are 14 inches in diameter, and round these the network of fibrous material is so thick that it is difficult to get near them. Through this mass of matting six immense spathes of flowers are now appearing on each plant, which shows plainly that the past severe winter has had no ill effects on them. They are planted in equal portions of loam and peat, of which they receive every year a top-dressing. When doing this a few weeks ago I had some of the roots laid bare, many of which were as thick as an ordinary-sized walking-stick.—W. WILDSMITH, *Heckfield, Hants.*

Yews and Cattle.—In a paragraph in THE GARDEN (see p. 370), headed "Yews not Poisonous to Deer," it is remarked that "it is imagined by clever observers that sheep and goats can eat Yew leaves with impunity." This statement, though not exactly incorrect, is, I think, calculated to mislead. There is no doubt that all sorts of cattle can, and frequently do, eat the foliage of the Yew with impunity; but, on the other hand, there is ample evidence to prove that at certain times, or under certain circumstances, it is a deadly poison to them. Our experience here is this:—We have lost during the last few years, through eating the foliage of the Yew, a horse, a donkey, a cow, and two or three sheep. The sheep died only last winter, and in their's, and in every other case cited, the cause of death was distinctly proved to be the foliage of the Yew, which was found in their stomachs. I therefore must confess that I consider Yew trees which extend within reach of any enclosures where stock is kept, very dangerous, and can only suggest one remedy, which is to cut them down.—F. S., *Kingston, Derby.*

NOTES OF THE WEEK.

— ALL who have the opportunity of seeing Mr. Jackman's exhibition of Clematises in the Botanic Gardens in the Regent's Park, should lose no time in doing so. Without a visit, it is wholly impossible to form a just conception of the beauty and novelty of the numerous Clematises now shown there. Not a few of them are kinds not yet in commerce, and of the highest merit.

— THE beautiful South African *Greyia Sutherlandi* is now in blossom at Glasnevin; this, and the Botanic Garden, Chelsea, we believe, being the only places in which it has yet flowered. Dr. Moore has succeeded in blooming it by keeping it rather closely pot-bound, and placing it in a very high stove temperature when making its growth. *Cheiranthra linearis*, a curious and beautiful New Holland plant, is also in flower at Glasnevin.

— MR. WILLIAM PAUL has formed a very remarkable exhibition of Roses in the Botanic Gardens, Regent's Park. The whole of the great Rhododendron tent is filled with them, and nearly all of them are unusually fine specimens of their kind.

— MR. GUMBLETON has brought us from Glasnevin a specimen of the lovely *Petræa volubilis*, which is now blooming profusely there. It has large loose racemes of violet and mauve-coloured flowers, the corolla of which is deciduous; the calyx is persistent, and brightly coloured. It is a plant which should be in every garden where means exist for its cultivation. It is a very old plant.

— THE offer of Mr. Albert Grant to lay out Soho Square as a public garden has been declined; but the inhabitants have resolved to remove the dilapidated monument, to enclose the square with new railings, and to lay out the ground in ornamental flower beds. The inhabitants will defray the cost of these improvements, and the square will be kept private, as heretofore.

— THE rare and beautiful *Calypso borealis* is now in flower in the York Nurseries. It is a hardy Orchid from the cold regions of North America, with rosy-purple sepals and petals, and a white tip, heavily blotched with cinnamon-brown. The new Alpine *Kalmia* (*K. glauca* var. *alpina*), which forms carpets about 2 inches high, with charming rose-coloured blossoms, is also in bloom. It has been sent to Messrs. Backhouse by their collector in the Rocky Mountains. *Gentiana verna*, *imbricata*, and *brachyphylla* (from Switzerland and the Tyrol), *Primula Dinyana*, the new and fine *P. Venzai* (in the style of *P. glaucescens*, but with the largest flowers of this section), a lovely pure white dwarf *Caltha* (*C. leptosepala*), from the Rocky Mountains, and the bright dwarf yellow *Ranunculus montanus*, from the Pyrenees, are likewise objects of interest. The new and strange *Echinocactus Simpsoni*, covered with spines like a vegetable "sea urchin," proves to be perfectly hardy, and promises abundant flowers. As a hardy plant, this denizen of the Rocky Mountains will be a new feature in Alpine rockeries.

— WE ought, perhaps, to point out that the plant exhibited by Mr. E. Wrigley, of Bury, some time ago, and also by the Rev. Mr. Norman, under the name of *Odontoglossum maxillare*, is not that species, but *O. madrense*. *O. maxillare* of Lindley is a membranaceous-flowered plant, nearly related to *O. Rossii*, *O. membranaceum*, or *O. Erenbergii*; whereas *O. madrense* is allied to the *O. cordatum* of Lindley, or the *O. maculatum* of the "Botanical Magazine." The pseudo-bulbs are sub-cylindrical instead of ovoid, and the spikes bear from five to six snow-white flowers of wax-like, almost leathery, texture, the sepals and petals being blotched with rich chocolate-purple at the base. The lip is cordate, having a bi-lobed crest blotched with lemon-yellow, and mottled with orange. This plant has recently been figured in the "Botanical Magazine," and also in the "Floral Magazine," under the name of *O. maxillare*. It has recently flowered freely in Messrs. Veitch's collection, where its delicious Almond-scented flowers lasted from five to seven weeks as fresh as when they opened.

— A VERY liberal schedule has been issued by the Leeds Horticultural Society for its exhibition in June next, and many inducements are held out to exhibitors to take part in the contest. Amongst the prizes offered in a few of the principal classes are the following:—Twelve stove and greenhouse plants in bloom, £20, £12, £8; twelve Roses in pots, £20, £12, £8; twenty Roses in pots, not more than 9 inches in diameter, £10, £6, £4; twelve *Pelargoniums*, £12, £8, £5; twelve Orchids, £12, £8, £4. Classes for fine foliage plants, Ferns, hardy and exotic Azaleas, Heaths, Fuchsias, fancy and zonal *Pelargoniums*, and cut Roses, receive most liberal prizes, as well as fruits, both in collections and single dishes. The Society finds horses, free of cost, to draw exhibitors' vans to and from the railway to the exhibition ground, and large roomy vans for those who take their plants in railway trucks. This is a great boon to exhibitors, who are generally victimised by the exorbitant demands made upon strangers for removing their plants at such times, and when they are powerless

to resist it. The Society also finds men to assist in the removal of the plants to and fro.

— THOSE interested in late-keeping Apples may like to know that the best flavoured of those now in Covent Garden is the Sturmer Pippin.

— THE new garden on the Thames Embankment will be opened this day, by W. H. Smith, Esq., M.P. It was designed by Mr. Vulliamy, and the work carried out by Mr. Meston.

— A NEW and improved edition of "Alpine Flowers for English Gardens," published by Mr. John Murray, is now ready, and a companion volume with coloured plates is in preparation.

— MR. ROPER, President of the Eastbourne Natural History Society, has just completed a "Flora of Eastbourne: being an Introduction to the Flowering Plants, Ferns, &c., of the Cuckmere District—East Sussex." The volume will be published by Mr. Van Voorst.

— THE small Carrot figured last week in THE GARDEN is now being sent in abundance from Paris to the London and other English markets. Vast quantities of Asparagus have lately arrived, and Lettuce is yet brought over in quantity. All these come from the Paris gardens.

— THE Central Horticultural Society of France announces that its annual exhibition will not be held in the usual place, the Palais de l'Industrie, this year, but in the Orangery and surrounding grounds of the Tuileries. It will be opened May 29, and closed June 6, and will comprise horticultural products generally, as well as garden implements, &c.

— THE introduction of every kind of plant, no matter what its nature or origin, is forbidden in Italy from the 18th of May. This is, no doubt, done from dread of the Phylloxera; but what a fatal obstacle to the progress of horticulture! The importation of American Potatoes, and of the sacks or cases in which they may have been packed, has also been prohibited at all the ports of Russia and Finland.

— A NEW Snowdrop (*Galanthus Elwesii*) is figured in the last number of the "Botanical Magazine." It is a native of Asia Minor, where it was collected, on the mountains near Smyrna, by Mr. Elwes last year. It bloomed this spring, and is thought to be distinct, though it bears considerable resemblance to *G. plicatus*, a name under which it was distributed some twenty years ago. It, however, differs in several respects from that kind, and is a good addition to our early-flowering hardy border plants.

— AT a recent sitting of the Central Horticultural Society of France M. Andry, in alluding to the death of the late M. Lucy, remarked that the latter was the first to recognise the peculiar merits of the Gloire de Dijon Rose, after it had been obtained from seed by M. Jacotot, who scarcely noticed it amongst many others. M. Lucy advised him to propagate and send it out, which was done, and the result has been that a most valuable variety has been added to our list of Roses.

— VINE culture in New South Wales is progressing very rapidly, the number of acres occupied for this purpose being 3,183 in 1873 against 2,568 acres in 1872, and the produce 575,985 gallons against 451,450 gallons. These figures relate only to the growth of Grapes for wine-producing purposes, but a considerable area is devoted to the cultivation of the Vine for other objects. In Western Australia also, where the soil and climate are eminently favourable to the growth of the Grape, this pursuit is becoming more general.

— MESSRS. THYNE'S very extensive and richly-stored new winter gardens at Glasgow were opened with some ceremony last Saturday. They are in the extreme western suburb of the city, and from the commanding terrace on which the principal houses are situated a magnificent view is got of the Campsie and Dumbartonshire hills, while in the immediate foreground is a beautiful artificial lake. The general plan of the garden is somewhat similar to that of Messrs. Veitch at Chelsea. The frontage extends 300 feet, and the space on which glass houses are erected is very extensive. Fronting the greenhouses is a fine terrace, 25 feet wide, planted effectively with Limes, Elms, Poplars, and the choicer Coniferae. A broad avenue of Coniferous trees divides the gardens into equal portions. Facing the west and parallel with the roadway are two conservatories, each 60 feet in length—one for stove and the other for greenhouse plants. At right angles to the conservatories are the Heath and show-houses, each 60 feet long, with glass pits of a length corresponding with that of the houses and forming, as it were, aisles to the main buildings. Parallel with the conservatories are six ranges of houses for propagating and forcing purposes, or for the display of exotic Ferns, the prettier sorts of foliage plants, Geraniums, &c., while the right and left of the whole establishment are occupied by a large Azalea-house and a cool Fernery—the latter especially being charmingly laid out.

THE GARDEN IN THE HOUSE.

CYCAS REVOLUTA FOR WINDOW RECESSES.

THOUGH we have long been familiar with this Japanese Cycas, it will, I think, be admitted that it is still one of the handsomest species in cultivation. When in full health and well-grown, with several tiers of beautiful fronds rising one above another to the latest-formed growth, standing almost erect in the centre, it is a very handsome and striking object indeed, and inferior to few, if any, fine-foliaged plants, either for exhibition or house decoration, though only well adapted for the latter purpose when the plants are young. Plants about one year old from corms, with one set of leaves about 2 feet high, fit single window-cases exceedingly well, the surface of the base being covered with *Lycopod*. No Fern that I know of can match a plant of this size, with its symmetrically arranged and erect, yet gracefully recurved, leaves, in a window-recess, half-hid by the folds of a lace curtain. To have plants of this description is in the power of anyone in possession of a somewhat old plant. If they will search under the soil about the base of the stem, they will discover perhaps from six to two dozen corms, about the size of Cocoa-nuts. If these are detached and potted singly in well-drained pots, and in tolerably rich soil, with the crown of the corm just peeping above the surface, and plunged in a moist stove with a bottom-heat of 80° or 85° about this season, they will start readily into growth, and form handsome little plants by autumn, and, if desired, they may be kept at this size for several years. I say desired, for, when they form the second and third set of fronds, the first fall down more, and the plants are then not so well adapted for decorative purposes, as the spreading foliage interferes too much with surrounding objects, and is otherwise in the way. In roomy spaces, and in front of halls, &c, they, however, do well enough. I took eighteen such corms from an old plant three or four years ago, grew them as I have stated, and we have most of them still with the original set of

leaves only; but they are now getting rather shabby and mutilated, and will have to be encouraged to make another growth this season, if all is well. They have been kept in this condition purposely by plunging them in a sub-tropical bed out of doors during summer, and wintering them in a cold greenhouse, which has prevented them making growth. When large specimens are desired, the plants should be grown in the stove and shifted forward liberally—for they are great rooters—using a substantial compost consisting of turfy loam, peat, and sand, and well-rotted manure, taking care to crock the pots carefully, and to water freely when the plant is growing. The

plant is very liable to brown scale—at least, in a warm stove—and, if this pest be not checked, it spreads with amazing rapidity on the undersides of the leaves. Soap and water and a brush are the proper correctives. A somewhat aged plant which we had here at one time, but which was exchanged for more useful stock, flowered twice in the course of a few years—I think, within three years. When sent away, it had two rings of empty seed-husks hanging round the crown. The flower, if we can call it such, is like an immense drab corona in the centre of the leaves, and sadly interferes with the shape and growth of the plant for the time being. Both *C. revoluta* and *circularis* are great ornaments in our plant houses. They are popularly, but erroneously, called Sago Palms; as they furnish none of the Sago of commerce.

J. S. W.

An Easily-arranged Plant-stand.

The pith of the stem of *C. revoluta*, however, abounds in starch, which is highly esteemed in Japan.

PLANT STANDS.

As regards the best mode of arranging flowering or foliage plants on stands for effect, there are many opinions; but one of the most important points for consideration is the time occupied in that kind of work. Many do not mind devoting half-a-day to the embellishment of the dinner-table, or to the arrangements of a bouquet; but gardeners, as a rule, can scarcely afford such a loss of time, especially where (as is now frequently the case) they have to furnish, not only plant

stands, but drawing-room vases, and make bouquet and coat flowers nearly every day in the year. Much time, too, is wasted in the arrangement of vases and tazzas, simply because no definite idea is formed beforehand as to the effect required; therefore, the plants are shifted and re-arranged in a hundred different ways to "see how they look," whereas a few minutes only should be devoted to such work. The accompanying illustration represents a bronze tazza, ornamented with well-known decorative plants. The margin is fringed with *Isolepis gracilis*, used expressly to tone down the harshness of the metal work. Two or three plants of the Palm-like *Carculigo* are placed in the centre; and these, by furnishing bold and graceful foliage, contrast well with the horizontal lines of the tazza below, while their cool and deep-toned greenness forms a pleasing contrast to the character of the stand itself. Heaths, too, and similar hard-wooded plants are added, and with good effect. F. W. B.

CULTIVATION OF WATER-CRESSES.

It appears that it was in the environs of Erfurt and of Dresden that the cultivation of Water-cress was first carried on to a large extent; but M. Cardon, seeing what was done with it in Germany, afterwards established its cultivation in the Valley of La Monnette, near Senlis—a species of industry for which the Horticultural Society of France awarded him its large silver medal. He sought for a soil watered by springs of running water, and, after a long search, he found, in 1811, at Saint-Leonard, in the valley just named, a piece of level ground of about 12 acres, which appeared to offer all the required conditions. Here he prepared numerous trenches for this Cress; some were at Saint-Firmin and others at Saint-Gratien. The elder Billet formed a number at Villemetry, as well as at Baron. The impulse to Cress culture being thus given, so many took part in it that, in 1835, large quantities of ground were occupied by it. The demand for it, however, had increased even faster than its production, and, therefore, new plantations were soon added to those just mentioned. These were established in 1843, at Gonesse, under remarkably favourable conditions.

Choice of Situation and Water.

Very sandy ground should never be chosen for the growth of Cress, because it lets the water escape by filtration, both through the sub-soil and through the belts of earth which isolate the trenches; chalky soil should also be rejected, because it does not furnish to young plantations the aliment suitable to them. The best soil for Cress is clayey loam, and what is said under this head applies, it will be understood, less to the surface properly so called, than to the bottom upon which the plantation rests. Nevertheless, the surface itself should be studied to some extent where trenches are employed, and the more level the ground is the better. The character and temperature of the water, as well as the amount of it, are also important considerations for the Cress grower, inasmuch as unsuitable water affects the quality of the crop. With abundance of water Cress produces large leaves of a fine green colour all the year round; while, with insufficient water, the plants grow weakly, the leaves are small, and are often burnt by heat in summer and frozen in winter. The mistake of most Cress growers is the desire to have more trenches than they can supply with water. Each trench requires 6 inches of water per minute. The Cress beds of Gonesse receive 7 inches of water per minute, which is equivalent to 3,700 gallons of water for 190 trenches, and there should be an out-flow for each trench, which, in times of drought, and in winter, should be reduced to a half, or even to a quarter, of what it is at other seasons, so as to ensure plenty of water in the trenches, as it is during the intense heat of summer and in winter that the plantations are in danger of perishing from want of water. Proximity to the source of supply is likewise an all-important consideration in the establishment of Cress plantations. If the source is too far off, its waters get heated in summer and too cold in the winter before they reach the beds, which, in severe winters, become frozen and perish. The necessity of having Cress beds as near as possible to the spring to some extent limits their length, but where it is absolutely necessary to establish trenches far from the spring, the water should be led to them in covered drains or canals, which will help to keep it warmer than it otherwise would be, and the deeper the spring the higher the temperature. The water of artesian wells is comparatively warm, but it is not the best for our purpose, nor should recourse be had to the water of small rivers—which are in reality but water from distant sources—except in cases of absolute necessity; and care should be taken not to mix it with that of the springs which supply the plantation. The chemical character of the water destined to supply Cress beds, too, should not be altogether overlooked. For example, some field waters communicate to

the Cress a marshy flavour, and load it with a yellowish deposit, and they are too warm in summer and too cold in winter. Water charged with carbonates of chalk and magnesia encrust the Cress, and should be avoided, as should also what is termed hard water, but ferruginous water is good, both as regards our own health and that of vegetation—a fact proved by the fine state of the beds at Gonesse, and above all at Duvy, which are supplied by water containing a very appreciable quantity of iron. Water, overcharged with iron, however, impairs the growth of the Cress, and contaminates it by an ochreous deposit.

Formation of Trenches.

The locality, soil, and water supply having been determined, the next thing is the formation of the trenches, their declivity, length, breadth, and depth. Experience has shown that the most convenient gradient is that of 5 inches to 260 feet. The length of the trenches is necessarily limited, in certain cases, by the extent of the grounds themselves; but, where there is room, from 260 to 270 feet constitute suitable lengths. If too long, the trenches do not receive the water running sufficiently briskly or fresh enough in summer, or warm enough in winter. Therefore, short trenches are, upon the whole, the best. The breadth to be given to such trenches, too, ought not to be a matter of indifference. If they are too broad, currents are often produced at their sides, or in some parts of their interior, leaving the rest of the trench a swamp, owing to the non-renewal of the water; a thick regular plantation, however, in some measure prevents the establishment of currents. In large trenches the flow of water is generally sluggish—a circumstance which not only enfeebles the plant, but produces a sort of marsh Cress, instead of spring-water Cress, which we require. Large trenches are more difficult to work than smaller ones, and they are more exposed to heat and cold—first, because of insufficient shelter; and, secondly, in consequence of the slower current of the water. Narrow trenches, on the contrary, produce a very fine Cress; they have, however, in practice, the following inconveniences:—They occasion a considerable loss of ground owing to the multiplicity of separation banks, the manure is drained off too speedily, and the isolation of the plants is interfered with; therefore, the breadth generally adopted is that of from 10 to 12 feet; it should not exceed 13 feet, and trenches of this width should not be adopted unless the supply of water is very abundant. The depth of the trenches necessarily depends upon the level of the springs; but, if too shallow, the Cress cannot be flooded; and, if too deep, isolation is diminished, and cutting is carried on under difficulties. If we consider that it is necessary to give the trench 4 inches of water, above which the Cress will be able to elevate itself from 6 to 8 inches, and that it is necessary that the walls of separation should serve for shelter, we come to the conclusion that the most convenient depth is from 18 to 20 inches. Between the contiguous trenches the earth dug out is often left; but as, in this way, too great an elevation is given to the walls which separate the trenches, it is better to remove the earth, and spread it on the neighbouring fields. The trenches should be parallel to each other, the top and bottom of each being placed, as much as possible, near the canals of supply and discharge. The bottom of the trenches should be well dressed or levelled, and put under water a few hours before planting. Each Cress plantation—that is to say, each series of parallel trenches—should have a common canal of supply to bring the water to it, and a canal of discharge, into which the water should flow upon coming from the trenches. The supply canal should run along the head of the trenches, and be connected with them by means of a single earthenware pipe, through which the water should pass equally to each trench. The dimensions, too, of both canal and pipes should be such as to enable the operator at any time, say during frost, to double or even, if requisite, treble the supply of water, which should always be sufficient for such purposes, or the crop will be a comparative failure when its marketable price is the highest. The outflow water is generally lost; but, charged with manure as it is, it might be profitably used for purposes of irrigation.

Planting Cress.

The months of March and August are acknowledged to be the most favourable times for planting; but in August fresh plantations should chiefly be made, as then the summer crops can be cleared off by taking up the plants, and no important stoppage takes place, as the parent trenches soon refurnish themselves with fresh Cress; while, in March, it takes much longer to repair the gaps made in the mother-trenches, and the new plantations are much slower in affording a crop than in August. There are cases, however, in which it is imperatively necessary to plant in March, as the beds often get destroyed in winter by frost. The bottom of the trenches having been previously moistened as already directed the planting is conducted as follows:—The Cress is thrown down in little tufts, at

distances of from 3 to 4 inches apart, beginning at the head of the trenches and finishing at the bottom. The arrangement is as much as possible in tranverse rows, the plants being put in in quincunx fashion, with their tops inclining towards the head of the trenches, that is, towards the source of the water, which assists them in righting themselves. It will thus be understood that the tops of the stems of the second row rest upon the roots of the first, those of the third upon the roots of the second, and so on to the end. The Cress readily attaches itself to the moistened earth, and after four or five days will have recovered itself, when it is immersed in 2 inches of water; five or six days after, that is to say, eight or ten days after the planting, it is pressed down with an instrument called a "schüele;" and, lastly, the trench, when the plants have acquired a certain height, receives all the water which is destined for it. It has been ascertained by comparison that the time for the first cutting is accelerated by about eight days, if, instead of throwing the Cress upon the bottom of the trench, it is properly fixed in the ground. Where the mud in the bottom of old beds needs cleaning out, and where the plants are not wanted for forming new beds, if the trench is thickly furnished with healthy vegetation, all that is required is to begin at one end and roll the Cress up as one would a carpet, clear out the bottom, and replace the Cress on its old bed. This being done, the water is admitted, and three days afterwards the Cress is dressed, and pressed with the "schüele" and the roller. This plan of renewing the beds is not only economical as regards labour, but has the advantage of not retarding the cutting, which, under the ordinary method, is otherwise thrown back nearly a fortnight. A plantation may be established by sowing Cress seeds, but this process is much slower than that of using portions of the plant. If recourse is had to seed it would be requisite, after having withdrawn the water, to sow upon the mud spread over the bottom of the trench; but few Cress growers would adopt this plan.

Cutting or Gathering Cress.

To gather Cress a man having his knees protected by thick knee-caps covered with strong leather kneels upon a plank thrown across the trench; with the left hand he seizes a handful of Cress, which he raises a little towards him, and with the right hand cuts it with a knife. When he has collected as much as will form a bunch he ties it with a twig of osier, of which he carries a small bunch at his girdle, clips off the too salient roots, throws the bunch into water under the shade of the embankment, and again commences the operation. A first-rate Cress cutter often cuts three bunches per minute, or 1,440 per day of eight hours; but he is reckoned a good workman when he can do two bunches per minute or about 1,000 bunches per day. At Gonesse and at Duvy the bunches are collected in covered pans, which traverse the water of one of the supply canals. Each bunch of Cress is about 6 inches long, 9 or 10 inches in circumference, and weighs about 18 dwt. The retail dealers of Paris generally divide them. Instead of cutting the Cress completely bare, they take only half or a third of the shoots, leaving the rest to be rolled on the bottom of the trench into which it pushes fresh roots and grows with increased vigour. The operation of cutting Cress being very fatiguing, in consequence of the inconvenient position which the workman is obliged to assume, the length of the day's work is usually fixed at eight hours. After each gathering of Cress the trench should have a good manuring and rolling.

Manuring, Spreading, and Rolling the Cress.

After each cutting the trenches are well manured by introducing it between the stems of the plants, and also by disposing of it in tranverse layers pressed tightly with the "schüele." The manure preferred is well-rotted cow dung, which is introduced into the trench between the plants, and is rammed in with the schüele, an implement consisting of a thick board several inches broad, and half the breadth of the trench in length, fixed obliquely to a long handle. Two workmen, walking opposite each other upon each side of the trench, with this ram in the manure, an important operation, which has for its object the fixing the dung about the roots of the plants, and thus preventing the mud of the bottom of the trench from soiling the green and marketable parts of the crop. This kind of manuring resembles, in some respects, the mulching of Strawberry beds. After the use of the schüele comes the rolling; this is done with rollers of a particular kind, furnished at their extremities with long handles, and drawn by workmen who walk upon the edges of the walls or banks that separate the trenches. This thoroughly fixes the manure in its proper place, and replants the Cress that had been raised in the operation of cutting, pressing the stems down in such a manner as to cause them to produce new roots, thereby increasing their vigour and adding to the quality of the produce. It was at one time a widespread practice to submerge

the crop during a great part of the winter to keep it from cold, but this has been found to deteriorate its quality both as regards colour and flavour. After rolling the plants in the trenches are all of one height, a condition which they retain until the next cutting. If a hole shows itself in this verdant carpet it is immediately filled up by throwing in some handfuls of Cress, which are pressed in with the point of the schüele. A little insect called the altise (*Altica sysymbrii*), often designated by the names of flea or tick, causes great injury to Cress in dry summers, attacking the old stems and perforating the leaves. This is, however, easily destroyed by temporary submersion of the trenches, and the dead insects are removed by means of rake-nets made of coarse linen. Water weeds are also often troublesome, and must be persistently removed.

Duration and Renewing of Cress Plantations.

In all well-worked Cress Plantations the trenches ought to be renovated every year, and it is very rare even in the case of tuft-planting, much less that of the carpet plan, that a single cutting is lost. Whenever decay shows itself, the plantation should be renewed immediately. The Cress is then torn up by the roots, and deposited on the bank which separates the trenches; but it ought to be stated that the method of rolling it up like a carpet, already described, is more expeditious, inasmuch as in this way growth is hardly suspended. When the Cress has been deposited upon the sides of one bank, the mud and detritus at the bottom of the trench is thrown upon the other, and thus all the trenches are renovated, care being taken to deposit the Cress and the mud in such a manner that the work may be carried on effectually and economically. The mud should be afterwards carted away. Vegetables are sometimes grown upon the banks; but their presence there impedes the proper working of the trenches. This objection, however, does not apply to Grass of which hay could be made. Sometimes, too, when Cress is unusually cheap, the water is drawn off the trenches themselves between May and August, and they are planted with light crops which yield a better return than the Cress. April and May are the months in which Cress grows fastest, and if the season is warm it must be often cut to avoid flowering; but all through the summer Cress still grows strongly, and yields abundant produce if properly planted and well supplied with water. Shade has been suggested by means of plantations of Osiers, Poplars, or Willows; but, in autumn, the leaves which fall into the trenches soil the crop. Besides, Cress can well withstand heat, provided it has plenty of fresh running water as has been already stated. The month of August is preferred to that of March for the formation or renovation of Cress plantations. In summer Cress plantations come to a stand-still, where the amount of water is insufficient, or where the plantation is established upon a turfy soil, and when it is too far away from centres of consumption. Winter is the season most dreaded by Cress-growers, as on it depends their profit or loss. In winter good prices are obtained, but frost often overtakes the trenches and stops the supply. Warm water—that is to say, from springs very near the trenches, which are sufficiently abundant to establish a rapid current—is what will save Cress beds. If the cold is sharp—and yet there is no fear of the water freezing—it must be so arranged that it only just covers the tips of the sprouts of Cress. But, if the cold is more intense, and the water is cold and insufficient in amount, the trench must be flooded in such a manner that the surface of the water rises above the Cress to the full extent of the thickness to which the layer of ice is likely to attain. As soon as a thaw takes place the ice should be broken and thrown upon the bank, and the level of the water lowered by degrees. Cress is sent to market in open wicker-work hampers. In the centre, or between the heads of the bundles of Cress, which are placed all round the hamper with their roots leaning against the sides, is fixed a shaft, which gives free passage to the air; twigs of Osier keep the bunches in their places, and prevent them from slipping into the ventilating shaft. If from any circumstance the transmission of the Cress to market is delayed, the bunches must be immediately untied and the Cress thrown into water and well shaded from the sun.

Uses of Cress.

Cress, as most people know, is principally consumed in its raw state. On the Continent, it is served up round roast and boiled meats, to which it serves as a condiment. Raw Cress is easily digested; a fact explained by the active properties which the plant possesses, and by the delicacy of the tissues. In this last respect, the cultivated plant, and, above all, that from well-kept plantations, is infinitely preferable to the harder, more bitter, and less frequent wild plant. Boiled Cress, prepared like Spinach, is often eaten, and is sweet and agreeable. It might, in fact, be called Cress-Spinach; and, being cheap in summer, might be used as a substitute for that vegetable. A good soup is sometimes prepared from Cress at the

Café Riche, one of the best restaurants in Paris. The employment of Cress in medicine is as ancient as the virtues attributed to the plant are numerous. The Romans knew it, and made use of it. It stood in the first rank in the Arabian pharmacopœia. But it is in modern times that it has been most appreciated. Cress is affirmed to be one of the best anti-scorbutics, and also to be eminently purifying and dissolvent. It is given to persons who have weak constitutions, and in cases of chest diseases, particularly incipient phthisis. Its juice is sometimes used as a gargle, and with good results. It may be added that Cress off ferro-iodinic waters ought to be most sought after, inasmuch as it possesses, in a greater degree than ordinary Cress, two valuable constituents—iodine and iron. We cannot, therefore, say too much to induce persons having at their disposal streams of this kind to utilise them by the formation of Cress plantations.

THE INDOOR GARDEN.

ON RAISING FERNS FROM SPORES.

THE propagation of Ferns from spores is, in general, very imperfectly understood, and this is more especially the case with species belonging to Gleicheniaceæ, Marattiaceæ, and Hymenophyllaceæ. The spores of some species vegetate very freely, and no difficulty is experienced in obtaining a stock of them; while others are less easily managed, and are, in consequence, much rarer. Mr. Mayer, of the Carlsruhe Botanic Gardens, has devoted special attention to this branch of cultivation for several years, and he has recently published the results of his experience in the "Gartenflora," the main points of which are given in the following remarks. The principal things to be considered in raising Ferns from spores are—selection of spores, time of sowing, pricking out of the young plantlets and protecting them from the numerous attacks of insects, Funguses, Algas, Mosses, &c. With regard to the choice of spores, ripeness is of the first importance. The presence of spores on a living plant or dried specimen is readily determined, and a lens of low power is sufficient to distinguish them from the spore-cases, surrounding hairs, &c. The spores of certain genera may be known by their colours, but farther than this, except with a very high power, it is impossible to go; hence, the necessity for great care in naming the spores at the time they are collected. To ensure, as far as possible, the presence of fertile spores, they should be taken from the most fully-developed part of the frond on which the spore-cases are just beginning to open; the portion of the frond bearing the spores should be detached from the plant and packeted in good paper, and the spore-cases will soon open and discharge their contents. This mode of procedure is more especially to be recommended in the case of those Ferns whose spores lightly float out, as it were, when the case opens, such, for example, as Angiopteris, Marattia, Gleichenia, many Cyatheaceæ, all of the Hymenophyllaceæ, and in *Todea superba* and *T. hymenophylloides*. To the foregoing might doubtless be added all those Ferns which grow naturally in a humid atmosphere, and are at all times more or less saturated with moisture. The question arises whether these Ferns can be raised in the ordinary way by simply scattering the spores over the surface of soil, as is usually done with most other Ferns. The conditions under which they are found growing naturally, and the experience gained by practice, teaches us that, if not impossible, it is at least very improbable. Ferns of this nature furnish fertile spores only when they are ready to fall direct from the mother plant on the medium (soil, turf, Sphagnum, &c.) on which the vegetative process and further development can take place. As soon as the spores have attained maturity, and before they fall from the plant, the first stage of vegetation sets in, hence the chances of success are much greater if a prepared surface is arranged immediately under the mother plant. As a matter of course, any interruption, however slight, of the vegetative process would deprive the spores of their vitality. As a proof of this statement, we may mention that we have never in a single instance succeeded in raising Ferns of this class from spores taken from dried specimens, whereas we have seen not only the prothallium, but also frondlets, on the fronds of the mother plant, as well as on the surface of the soil around and under it. Furthermore, it may be added that the material (with the exception of *Hymenophyllum Tunbridgense*) used by Weltenius in his "History of the Development of the Hymenophyllaceæ" to illustrate the germinating spores and the origin of the prothallium, was all taken from dried specimens. With regard to the best time for raising Ferns, the winter should be chosen, although any other time would do as well, because they require a great deal of attention, and at this period the gardener has most leisure. Very much patience and time must often be expended before the cultivator

has the pleasure of seeing his labours rewarded with real results. It is not necessary to insist here upon an uniform temperature, a constantly humid atmosphere, and subdued light—conditions most easily obtained in the winter season, when the plants are young and tender. The spores should be separated as much as possible, and not sown very thickly, otherwise it is difficult to part the young plants, and they have to be pricked out in bunches at first, and afterwards, as they grow larger, parted again and again, until they are singled out, an operation that greatly endangers the roots. Except for tree Ferns, or rare species, it is not of very great importance to have single plants. When pricking out, it is desirable not to have the young plants longer than is absolutely necessary in the drier atmosphere of the potting-house. One of the most difficult tasks, which has already been alluded to, is to protect the prothallium from the depredations of insects, Funguses, &c. The difficulty is not alone in the delicacy and tenderness of the plants themselves, but rather in the slow rate of development from the spore to the formation of the fronds, which, in some instances, occupies several months. Of course, the more extended the period of development, the greater the dangers of invading liver-worts and other rapid-growing Cryptogams; and herein may be sought the cause of the disappearance of many beautiful Ferns, not easily propagated in any other way. The interval between the germination of the spore and the formation of fronds is naturally the most precious period. The length of time spores lie before germinating depends upon a variety of circumstances, such as age of the spores, the temperature to which they are exposed, the temperature of the water with which they are moistened, &c.—points very difficult to ascertain and fix in the degree most favourable for different species. A long series of observations and comparisons can alone settle these questions. As already stated, the most successful results are furnished by those species which develop fronds from the prothallium in the shortest time. It will be observed that sowings of such genera as *Gymnogramma*, *Cheilanthes*, *Ceratopteris*, *Notholæna*, *Pteris*, &c., are almost always attended with favourable results, while success is much more uncertain with many tree Ferns, and the genera *Acrostichum*, *Lygodium*, *Davallia*, *Gleichenia*, &c. But now for the best means of removing or lessening the many dangers which beset Ferns in their earliest stages of growth. The first and most important thing to do is to extirpate, as thoroughly as possible, all vegetable and animal life inimical to the well-being of young Ferns, in the place where it is intended to attempt their propagation, and particularly to prevent their breeding or fructification. The peat, or other material, in which the Ferns are to be raised, should be previously baked or soaked in boiling water, and used immediately after this operation. It is also inadvisable to do the work of preparing and sowing the Fern spores in a place where there is any chance of spores of other Cryptogams floating about in the air, and least of all in a Fern-house. We know gardeners who will scarcely be convinced that the spores of Ferns do not sometimes produce something totally different from the mother plant. It is a fact that a crop of some common *Pteris*, *Gymnogramma*, or *Aspidium*, often, indeed usually, spring up where we expected something quite different; but the explanation is not difficult when we remember that the air of a Fern-house is more or less pervaded with the spores of these free-fruited, rapid-growing species. Under such conditions, the species of less rapid development are almost certain to be displaced or choked; but, with every care, it is impossible to effectually exclude all foreign spores and germs, which are conveyed partly by the air, and partly in the rain-water used for sprinkling. In the case of species of slow development, it is a good plan to prick them out afresh two or three times, according to circumstance, using each time soil prepared in the manner already indicated. The floor of the pit or box, of whatsoever it may consist, in which the pots containing the spores are placed, should also be soaked with boiling water. Insects, and other injurious little animals, may be killed or driven away by fumigating with tobacco-smoke. To the foregoing general remarks we will append a few special observations on the propagation of the genera *Marattia*, *Gleichenia*, and *Trichomanes* from spores. We are well aware that these observations are incomplete, but they may afford the cultivator some clue to the successful increase of these attractive plants, and thus become instrumental in their wider distribution in gardens. Among the Marattiaceæ, we were not only successful in bringing the spores to germination, but also in raising a considerable number of plants of *Marattia latifolia*. What has already been noted with regard to the ripeness and collection of spores applies with especial force to the Marattiaceæ. The spores of species in question lay four weeks from the time of sowing till the first development of the prothallium, and four more weeks elapsed before it was large enough to prick out; but from this time forward from six to eight months, and in some cases

even a longer time passed before the first frond was produced. Instead of forming fronds, the prothallium spread out very widely, and the experiment of cutting it up was tried, care being taken to leave one of the deeply-cut bays on each piece, as the first fronds always appear on or near the deepest part of such an indent. The result was surprising, for in from four to six weeks nearly all of the pieces had produced their first fronds. The relatively rapid development of fronds was the effect of cutting up the prothallium. In the *Gleicheniaceæ* success attended the experiment repeatedly tried with spores of *Gleichenia dicarpa*, and numbers of plants were raised. Spores of other species could not be procured, which is probably the principal difficulty in the way of raising them from spores. The prothallium of *G. dicarpa* was just five months from its first appearance before it produced a frond, and, therefore, it was

plant of dense habit, and one which bears enormous trusses of brilliant orange blossoms, with which its glossy fresh green foliage forms a striking contrast. As an exhibition plant, it must soon become a general favourite. The stock of this charming addition to this handsome genus—in which we have now oranges and scarlets of the most brilliant description, as well as whites of the purest character—has been bought by Messrs. E. G. Henderson, of the Wellington Road Nurseries, St. John's Wood, and will be sent out some time during the forthcoming season. B.

How to have *Rondeletias* in Bloom in September.—How am I to have *Rondeletia speciosa* in flower in the beginning of September? The plant is at present in a stove, which is kept at

Fraser's Ixora (*I. Fraserii*).

necessary to prick them out several times. Repeated experiments were made with the *Hymenophyllaceæ*, both with spores from dried specimens and direct from living plants; but not one succeeded, though the prothallium of a *Trichomanes* was observed on and beneath the fronds of *T. attenuatum*. Its development could not, however, be followed up. H.

FRASER'S IXORA.

(*I. FRASERII*.)

THIS fine stove shrub, which is undoubtedly one of the best of the orange-flowered *Ixoras*, formed part of a batch of seedlings raised by Mr. Fraser, of the Lea Bridge Nursery. It was first exhibited at South Kensington, in July last year, when it was deservedly awarded a first-class certificate. As will be seen by our illustration, it is a

about 65° at night, and where it has made growths about 6 inches long; therefore it will be in bloom before the time mentioned.—A SUBSCRIBER. [*Rondeletia speciosa*, when in good strong condition, will generally flower twice during the summer, the second time in September; but, to ensure the second blooming by that time, the plant must be started early, say in the beginning of February, in a night temperature of 65°, with a rise, as the days lengthen. A plant, in the condition just described, is, I fear, not early enough to produce a second crop of flowers by the time required, and the first will most likely be over. I should recommend pinching out the points of the shoots now, an operation which, if the plant is strong, will cause it to break in a double manner, producing thereby a proportionate increase of bloom. If, after this, it should form its flower-buds too soon, it will bear during the summer being kept at the warmest end of the greenhouse; but the flowers of this plant like a considerable time to open after they are formed.—T. BAINES.]

CULTURE OF MASDEVALLIAS.

THERE is no more beautiful tribe of Orchids than the various kinds of Masdevallia. They combine somewhat of the grotesqueness of the Orchid family with, in some instances, gorgeousness of colouring. Until within these last few years they appear to have been little known, but what with the improved modes of packing and the rapidity of transit to this country, together with the cool treatment which is sensibly appreciated and acted upon, they appear now in something like the beauty which they display in an indigenous state. Dear they are to buy certainly, but once on the right road of proper culture they more than repay the investor. So far as can be seen, the high prices once obtained for them must in time give way, although the best varieties are always sure to realise full market value. The question now with anyone concerned with Orchids or in Orchid culture, is not so much the possession of a particular species, as of a first-rate variety of that species. Like Amaryllids and other choice plants, some varieties may not be worth as many shillings as others may be worth pounds—the one you look upon as a weed the other as a gem. Regarding the culture of Masdevallias, it may help some of your readers if I state that, when properly in hand, they are the most facile of Orchids to encourage towards strong growth and prolific flowering. Some species may be grown too strong for a proper state of inflorescence, such as Vandas, Aërides, and similar kinds; but you may cultivate Masdevallias with all the luxuriance it is possible to create, and yet they will flower and continue to flower, and always with corresponding vigour. You cannot do this, however, without placing the plants in a proper temperature, which means that it should be moist—much moister than many Orchids will bear; it must be cool—much cooler than for the majority of even cool Orchids; and it must be toned down from the pressing and exhausting influences of solar heat, or there can be no success worthy of the name. One is accustomed to see leaves looking bleached at the extremities; this is caused by excessive heat and a deficiency of water. Properly cultivated Masdevallias should not have this appearance any more than properly cultivated Odontoglossums should have leaves of the texture of silk paper, which fall by their own weight. He who does not get over this defect has something to learn in the cultivation of the most beautiful of the many beautiful tribes of Orchids. Some of the families look shabby at certain periods of the year, and yet are in a good state of cultivation notwithstanding their defective appearance,—as Cattleyas, for instance, that require a thorough ripening of pseudo-bulbs to yield the best quality of flowers; but the plants in question are not healthy if they are not always green. There is no great difficulty in ensuring that this shall be the case; but they must be kept cool and moist near the glass, and, moreover, in a healthy feeding medium. Their white larva-like roots show the experienced cultivator that they require something of the richness of ordinary cultivation, that they are purely and simply a sub-species of a terrestrial plant, and that they must be treated accordingly. Some may object to this description of their habits, but it is no more strange that they should be treated as terrestrial plants than Calanthes, which do uncommonly well when grown in this way, notwithstanding their epiphytical nature. If the grower wishes a first-rate return, he must so treat them, and he will find that it will add to his fame as a cultivator, and to the value of the specimen he is experimenting upon, if he gives the established plants a little weak diluted manure-water. It does them as much good in proportion to their stature as it does Eucharis amazonica, which so greatly delights in good feeding. Be cautious, however, and rather err in giving too little than too much. Do not starve the plants, either, by putting them in sandy, peaty, fibry compost; it may look well to those accustomed to such a way of potting, but it is only respectable starvation. These are but a few hints as regards their cultivation; but, simple as they are, if the grower acts upon them he will find a good outcome. I am not speaking exactly without experience; for I happened to be fortunate enough to grow what is vulgarly called the “deil’s dozen” of Masdevallia Harryana, bought from Messrs. Veitch for M. Veitchii, before, of course, Harryana was known. They cost the late Mr. Dawson twelve guineas; and, after a three years’ growth, and dividing up, and potting in, these original thirteen plants realised, at the

various sales, within a few shillings of £250. That was a fortunate hit; others did not prove so good an investment; but the instance just referred to shows what may be done by judicious culture. And this brings me to the concluding remark, not the least important, and that is, that the plants, if any amateur wishes to make the most of them, should be broken up and grown on afresh, as is done in the case of some Sarracenias, which, when grown singly and grouped together, make marvellously effective exhibition plants. If any of your readers wish any further information upon the subject, what I can give is freely at their service. JAMES ANDERSON.

Meadowbank Nurseries, Uddingston, Glasgow.

GREENHOUSE ACACIAS.

ACACIAS bloom from midwinter to midsummer, and the long-flowered covered shoots are serviceable in many, if not in all, kinds of floral decoration. I do not agree with those who consider that Acacias are only adapted for decorations on a large scale. Small plants flower for years before they become too large for ordinary houses, and as rafter and pillar plants many varieties can be permanently cultivated in all kinds of cool glass structures. They also attain the proportions of trees, in which state they are impressively grand when in full bloom. Examples of this are to be found in the large temperate house at Kew, and in the conservatory at Floors Castle. The specimen of *A. Riceana* at the latter place is unique, and is a most attractive object at all times, more especially when its long, graceful, weeping branches are clad with pretty pale yellow blossoms which are produced abundantly in March, April, and May. Some varieties can be readily increased from the roots and sucker-like shoots which they sometimes produce. The easiest way, however, is to propagate from seed, which is formed very freely in most instances. The seed is mature and fit for gathering when the outside of the pod becomes hard and assumes a brown colour; if left hanging after this time the capsule opens and the seed drops out. It may either be sown immediately after it is gathered or it may be kept dry for years and put in at any time. If kept for any length of time the seed gets very hard and should be soaked in water for a day or two before it is used, or it takes a long time to germinate. A single seed may be placed in the centre of a 3-inch pot, or a number may be put into a 5-inch one; in either case a mixture of loam and peat in equal parts, with enough of silver sand to make it glisten, should be used. The seeds should rest one inch from the surface; a bottom-heat of 70° hastens their growth in the winter and spring months, but during summer and in a mild atmosphere they germinate fast in a close frame without any plunging. Care must be taken never to let the soil in which the seed is sown become dry, and those raised singly in pots need not be hurried into others, for a 3-inch pot will accommodate any size under 8 or 10 inches in height. Those sown together should have the ball turned out of the pot entire, each plant being broken away with a quantity of soil attached to the root, and potted separately into 3-inch pots, after which a close, mild, moist atmosphere should surround them until a few inches of wood have been made, when attention must be given to their

General Cultivation.

At the second and all subsequent shifts the compost should be much the same as that first used, but in a rougher state. The plants will grow in good loam and sand, but, unless where peat is naturally bad, this does them no harm. Ample drainage is indispensable at all times. From a 3-inch pot they may be potted into a 5 or 6-inch one, and from this size into an 8-inch one, which will hold serviceable plants for years. Unlike some plants, Acacias do not bloom more freely when pot-bound, yet the roots should never be allowed to become an intricate mass before they are transferred to a larger-sized pot. In 10 or 12-inch pots, fine bushy plants, 5 and 6 feet high, can be accommodated. And these are extremely useful for setting in the centre beds of greenhouses and conservatories, where they associate well with Camellias, Azaleas, &c. Plants, in small or large pots, may be grown to any size or form, for, although they are naturally inclined to move rapidly upwards, this is easily prevented by cutting the leaders well in, and directing the principal growth about the base. Young plants may have the point taken out of the leading shoot when it is 6 inches high. For standards this may be left alone until the stem has attained the desired height, and the lower shoots should be taken off as upper ones are produced, until a well-balanced head on a clean stem is the result. This need not be included in the annual operation of pruning, which it is often necessary to perform on old plants in order to keep them in shape after they are fully formed. Pruning or cutting back should be done immediately the plants are out of flower, and before the young

growth appears, but unless the branches are becoming straggly no cutting back is needed. In either case they may be allowed to make their growth on the spot where they bloomed, or, if they are in the way there, in some other place with a temperature similar to it. When the young growths are pushing freely, large plants should be re-potted. A close atmosphere for a short time after this sustains the vigour of the young shoots, which soon bear full exposure outside in favourable summer and autumn weather. A greenhouse temperature is sufficient for them at all seasons, and they may be used for decorative purposes in October and November. The best-ripened wood blooms earliest, and a few well-managed plants will flower from January until May. When the plants become too large for pots, they succeed remarkably well planted out. This should be done when they are in the same state as that in which they should be when re-potted. The depth of soil may be from 2 to 4 feet, with from 3 to 6 inches of drainage. The one at Floors, to which I have referred, and those at Kew, are planted out. This method should not be practised unless plenty of head-room can be given to the plants. To plant out and be constantly cutting the best of the shoots back to keep them from growing against the roof, is a sure means of getting a great many stumps; but, when the branches can ascend unrestricted for 12 or 15 feet, the effect is worth all the room which is taken up. Where there are no means of growing Acacias in tree forms, they may generally be grown as climbers. From 6 to 30 feet of rafter or pillar may be covered with a single plant in a very few years. For the shorter distance it may be grown in a pot; but, for the longer, abundance of root-room should be provided, either by planting in a bed or border, or in a large square box or tub. Abundance of water should be supplied when the plants are growing freely, and it should be withheld when there is no great demand for it, ripening the wood by constant exposure after it has been fully made, and cutting the shoots in to keep them proportionate, and fitting to the position which they fill. Insects are not very liable to make their appearance on Acacias, unless they come in contact with other infested plants; but it is very difficult to get the mealy bug eradicated when once it gets amongst the leaves; in fact, it cannot be cleaned except by cutting the branches off nearly to the stem, and allowing new clean wood to form. Scale also works, when the opportunity is offered, on the surface of the bark. It is more inclined to confine itself to the thick parts of the wood than amongst the foliage. Brushing, and particularly scraping, are the easiest and surest means of eradicating it. Red spider seldom approaches healthy plants, and those subject to it may be relieved of its presence by frequent syringing with water.

J. MUIR.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Amherstia nobilis from Cuttings.—This fine stove tree is propagated in the Handsworth Nursery freely by means of cuttings, and a fine stock of young plants may now be seen there raised in this way.—W. HOWARD.

Layering Lapageria alba.—Messrs. Fisher, Holmes, & Co. have a fine variety of this which they are increasing by means of layers. A hundred and thirty young plants of it have been raised by merely pegging down the shoots in rough sandy peat, and potting them off when sufficiently well rooted to bear separation. The layering should be done as soon as the wood is thoroughly ripe.—W. HOWARD.

Fine Dendrobium densiflorum.—I have placed in our conservatory to-day a plant of this Dendrobium, on which there are twenty-seven spikes of flowers. On some of the shoots are three spikes, each about 8 inches long, and bearing thirty-six flowers. The plant is very pretty, and finer, though not more showy than the one of *D. fimbriatum*, of which I lately gave some account. It lasts a shorter time in flower than *D. fimbriatum*.—ROBERT MACKELLER, *Abney Hall, Chesham*.

Primula cortusoides amœna lilacina.—This is the most robust of all the *P. amœna* family. The flower-stems are stiff and the flowers erect. It makes a useful pot plant, and does well for spring bedding. This variety and *P. cortusoides amœna* are the two best. Then comes *grandiflora*, which has the largest flowers, pale red outside and white inside. *P. amœna grandiflora alba* has also large blooms, but very flaccid. I have also *P. amœna alba* and *P. cortusoides* in bloom; both small, but pretty.—A. D.

Hepaticas from Seed.—Not long ago I showed how large supplies of seed might be obtained from Hepaticas and how easily hybrid varieties might be raised. I sowed seed of my forced plants of them on April 12th; it is coming up satisfactorily and I am curious to know when I shall get the seedlings to bloom. I sow in pans in the lightest vegetable soil and prick out each seed individually, as all will grow if properly ripened. I would advise keeping the pans under glass and thoroughly moist. I never saw Hepaticas seed so freely as they have done this year, and no one should lose the opportunity of increasing *Hepatica angulosa* by this means.—FRANK MILES, *Bingham, Notts*.

Orchids in Flower at Gunnersbury.—Several plants of *Odontoglossum Alexandræ*, some having two spikes bearing upwards of twenty flowers, are now in fine condition at Gunnersbury, as are also *O. Rothschildii*, which was shown under that name last year, and which has on a single spike eleven flowers, spotted beautifully with purple, and brighter than when last exhibited; *O. Pescatorei*, a handsome species, bearing thirteen flowers upon a spike; *O. niveum majus*, with five spikes and sixty flowers; and *O. vexillarium*, throwing up two fine spikes from one bulb, with seven flowers on one and six on the other. The whole were in perfect health, and Mr. Richards informed me that he had not been without flowers of *O. Alexandræ* for a year, which is saying a good deal for this lovely Orchid, the blooms of which are invaluable at any season for bouquets and for table decoration.—A. OUTRAM.

THE FRUIT GARDEN.

SHADING PINES.

I NEVER expected to convince Mr. Muir that Pine shading was unnecessary; nor must he hope to satisfy me that the burning of the crowns of large fruits in the month of May, which he alleges he has seen, is to be traced primarily to an absence of shade rather than to some radical error in the treatment of the fruit. The fact that he has seen Pine-shading practised in six different Pine-growing establishments appears to be an altogether insufficient justification of the practice. I maintain that if Pines are grown properly, and are in a thoroughly healthy state, they no more require shading than Vines or Peaches, or than pits and frames that contain early Potatoes. I do not for a moment deny that Mr. Muir's Pine-apples, or even those of the "six different establishments," required the kind of attention he advocates to save them from being burnt, blotched, or contorted; but it only shows they were so weakly and badly grown that they could not support the strength of the very rays that are the life of fruits in a less abnormal state. Mr. Smith, in his remarks on Pine-apple culture (p. 387) does not even hint at shading; but I believe he touches the right note when he counsels the admission of air some time before sunrise. My own experience, which I may at least refer to as a somewhat lengthened one, has led me to the conclusion that air should even be admitted throughout the night whenever the weather is sufficiently favourable. The gases that accumulate during the night are thus dispersed before the sun strikes the glass. Apply freely but methodically moisture charged occasionally with ammonia, and give air at the front of the Pine pit or other structure in which the plants may be. In excessively hot weather the lights of Pine-pits may be tilted in such a way as to reduce the force of the sun's heat at mid-day. These matters to really practical gardeners are simple enough, and those who systematically adopt a method, which I myself have invariably found successful, will never find it necessary to apply shading to Pine plants during any stage of their growth. Painting the glass with milk and whiting is nothing more nor less than permanent shading by night and by day, during sunshine or cloud, until it happens to be washed off by rain; and plants thus coddled may attain any age before they fruit, as in the case of those Queens of which we have lately heard complaints.

JAMES BARNES.

Exmouth.

NEW PEARS.*

ROUEN is becoming a place of note among horticulturists as a new fruit-raising centre, and a competitor with some of the well-known Belgian towns for fame. Already it has produced some varieties that have proved of first-rate quality. It is now about twenty years since the *Passe Crassane*, raised by M. Boisbunel, fruited for the first time; and now it is a general favourite in the gardens of France, Germany, England, and even America. M. Pynaert, a Belgian pomologist, passes his opinion of the merits of the following varieties raised by M. Sannier, based upon specimens received direct from the raiser. The system of nomenclature adopted by M. Sannier is very severely criticised, and deservedly so, for long names are the plague of gardeners and a reproach to the giver. M. Sannier's names run chiefly upon the *souvenirs*, of which the following are specimens:—*Souvenir du Vénérable de La Salle*, and *Souvenir de la Rue Mare-au-Trou*. We agree with M. Pynaert in recommending the suppression of such long-winded names in favour of more simple appellations. At the end of February only two of the varieties were quite ripe. The first was *Louise Bonne Sannier*, a fruit of medium size and excellent quality, of which we shall shortly give a description; the other was *Beurré Henri Courcelle*. The specimen tasted would have kept longer—probably till the end of March. It is a delicious fruit. The flesh is exceedingly delicate, buttery, and melting, without the least trace of grittiness in the centre. It is abundantly juicy, very sugary, slightly and very pleasantly acidulated, with an aroma peculiarly its own. As one of the judges at the fruit show at Anger's last year, we tasted another variety, raised by the same gentleman, *Souvenir de Sannier Père*. Although this fruit was exhibited under unfavourable conditions a favourable judgment was passed upon it. But this by no means comes up to the raiser's estimate, who describes it as a magnificent and exquisite fruit, of an extremely agreeable perfume. However, it is impossible to form a correct idea of the merits of a new fruit at an exhibition.

The *Bergamotte Arsene Sannier* is still quite green in my fruit room. According to M. Sannier, it is a handsome and an excellent fruit, which will keep till May, and has a delicate flesh of delicious flavour. We can hardly suppose that M. Sannier would give his own name to a variety of inferior quality. This variety and

* Raised by M. A. Sannier, of Rouen.

the Beurré Henri Courcelle remind one in some measure of the Bergamotte Esperen, from which they were raised. The latter is undoubtedly an improvement, and if it also possesses the other qualities of its parent, especially its hardiness and fertility, it will deserve a place in every choice collection. This and the Bergamotte Arsène Sannier, Souvenir de Sannier Père, and Beurré Amandé—so named doubtless on account of its very decided Almond flavour—have been sent out this year. Another collection of ten new varieties, bearing the objectionable names referred to above, are announced to be sent out in the autumn of 1875. M. Sannier, of Rouen, a raiser of some excellent Pears and other fruits, has hit upon an ingenious method of accelerating the fruiting of seedling fruit trees. True, it is not altogether new, for a similar procedure is practised by fruit forcers in this country to induce fruitfulness. It consists in pot-culture for several seasons of those whose early fruiting is particularly desired.

Leonce de Vaubernier.—A coloured portrait of this Pear, which was raised by the late Léon Leclerc de Laval, and sent out by M. Hutin, is given in the April number of the Bulletin of the Belgian "Cercle d'Arboriculture." It had not been previously described, except in general terms in the catalogue of the firm Simon-Louis, where it is placed in the third class for quality; but this class, it should be mentioned, includes many very good varieties. M. Burvenich says that although he cannot affirm that it is really a first-class variety, yet he believes the firm mentioned has underrated its merits. It is of very regular obovate shape, slightly hollowed at the sides; skin, rough, russeted on an olive ground, strongly tinged with deep red and dotted with yellow on the sunny side; stalk, short, woody; eye, rather large, open, calyx-lobes coriaceous; flesh, yellow, moderately fine, very agreeably perfumed, and of quite a peculiar texture; it is at once unctuous, firm, and compact. The wood is of a very bright shining brown, thinly besprinkled with small elongated lenticles; buds, moderately large, on short stout shoots. An exceedingly prolific variety, either on the Pear or Quince stock, of moderate vigour. Altogether the qualities of this Pear constitute a distinct type in colour, flavour, and the substance of its flesh. Briefly, it is a good fruit, ripening in September before a great glut of varieties come in. H.

THE TRUE FRENCH PARADISE APPLE.

THIS is figured in the last number of the "Florist and Pomologist," and its true character again pointed out, as it was seven years ago by the founder of THE GARDEN, it being pronounced tender and useless at that time by various gentlemen whose opinions had much weight in such matters. As no allusion is made in the article to this fact, it may be well to bear in mind the opinions held of the stock seven years ago, and contrast them with those which follow:

"We have much pleasure in submitting a figure of the true French Paradise Apple, the Pommier de Paradis, which, when used as a stock, is of such inestimable value in inducing dwarfness and prolificacy in other varieties of Apple. 'Mr. Barron has collected from various sources, British and Continental, a number of Apple stocks, which are growing side by side, so as to admit of easy comparison. Side by side, also, are various Apples worked on the several stocks. There are the Crab stocks (Pommiers francs), with long, spreading, rigid, wiry, tangled branches, of a deep purplish-black colour, and at the time of our visit (April 11) with no vestige either of leaf or flower to be seen. There is the Dutch Paradise, of straggling habit, with olive-coloured shoots, in full leaf, but without a flower. There is Mr. Rivers's Nonsuch English Paradise, destitute of leaf or flower, and Rivers's Miniature Paradise, equally late, and scarcely justifying its name. There is Mr. Scott's Paradise, of very distinct somewhat pyramidal habit, in full leaf, but with scarcely a flower to be seen. There is the Doucin, also of pyramidal habit, and producing flowers early. Then there is the true French Paradise, Pommier de Paradis, obtained from the most reliable sources in France, which must unquestionably bear away the prize for precocity of flowering and abundance of bloom. By precocity we mean not early flowering with regard to season, but with reference to age also; while other stocks of the same age have not reached the fruiting stage, this one has already done so. It is of rather straggling habit, but full of flower. While some stocks at the time of our visit were showing few flowers and others none at all, this one stood out in the row sheeted over with pale pink blossoms. These qualities it very markedly contributes to the grafts. Short compact growth, and early and abundant flowering, characterise the scions grafted on this stock, as they characterise the stock itself. A long row in one of the quarters, consisting of various Apples grafted on this stock, side by side with rows grafted on other

stocks, is one of the most striking illustrations of the effects and consequences of grafting it has ever been our fortune to witness. The difference in appearance is so great that it would almost seem as if the one row were cultivated for fruit, the other for timber! By way of illustration we may mention the Rhode Island Greening, a vigorous-growing kind, but which when worked on this stock becomes subdued, assumes a short, bushy habit, and produces an abundance of early bloom. What was formerly grown at Chiswick under the name of French Paradise is quite a different thing, and relatively very inferior. Of course this Paradise stock is not intended for orchard use, where the freer-growing stocks are preferred."—(Mr. Barron in "Chronicle," 1874). The French Paradise stock referred to in these remarks is that which we now figure. The plant is of spreading habit, with purplish shoots. The inflorescence is abundant, and precocious as to season, and also in relation to the age of the plant. The young leaves are glabrescent, oblong-lanceolate, the apex acute, the base rounded, the margin crenulated, the crenulations mucronulate; the petiole is less than half the length of the leaf, setose, and the stipules are linear-subulate, as long as the petiole. The peduncles are about three-quarters of an-inch long, setose; the flower-tube glabrous urceolate, reddish, one-eighth of an-inch long; the calyx-lobes triangular, gradually acuminate, setose within; the petals concave, oblong-obtuse, tapering at the base into a short stalk, and provided with a few cottony hairs on the inner surface; the styles are crested at the base for a short distance, and there slightly covered with cottony hairs, dividing above into five stigmatic branches. The fruit, which is a really good early eating Apple, is, according to our notes, of medium size, oblate, somewhat angular, yellow, changing on the exposed side to deep golden-yellow, and sometimes having a thin flush of rosy-red. The eye is broad, but closed, sunk in a rather deep cavity. The stalk is short, scarcely projecting from the hollow, which is not so deep as that of the eye. The flesh is pale straw colour, fine grained, solid, juicy, and with a brisk agreeable flavour. It ripens in the middle and end of August, and would form a good useful early dessert Apple, independent of its value as a dwarfing stock for Apple trees grown in the bush or pyramidal form."

T. MOORE, in "Florist," May, 1875.

PHILADELPHIA HORTICULTURAL EXHIBITION.

As this exhibition promises to be the most remarkable one to be held for some time to come, we have thought it desirable to give an illustration of that section which is to be devoted to horticulture. As will be seen, it is an extremely ornate building, and one which is to remain in permanence as an ornament of Fairmount Park. It is located on the Lansdowne Terrace, on the north of the main building and art gallery, and has a commanding view of the Schuylkill River and the north-western portion of that city. The design is in the mauresque style of architecture of the twelfth century, the principal materials externally being iron and glass. The length of the building is 383 feet; width, 193 feet, and height to the top of the lantern, 72 feet. The main floor is occupied by the central conservatory, 230 by 80 feet, and 55 feet high, surmounted by a lantern 170 feet long, 20 feet wide, and 14 feet high. Running entirely around this conservatory, at a height of 20 feet from the floor, is a gallery 5 feet wide. On the north and south sides of this principal compartment are four forcing houses for the propagation of young plants, each of them 100 by 30 feet, covered with curved roofs of iron and glass. Dividing the two forcing houses in each of these sides is a vestibule of 30 feet square. At the centre of the east and west ends are similar vestibules, on either side of which are the restaurants, reception room, and offices. From the vestibules ornamental flights of stairs lead to the internal galleries of the conservatory, as well as to the four external galleries, each 100 feet long and 10 feet wide, which surmount the roofs of the forcing houses. These external galleries are connected with a grand promenade, formed by the roofs of the rooms on the ground floor, which has a superficial area of 1,800 square yards. The east and west entrances are approached by flights of blue marble steps from terraces 80 by 20 feet, in the centre of each of which stands an open kiosque 20 feet in diameter. The angles of the main conservatory are adorned with eight ornamental fountains. The corridors which connect the conservatory with the surrounding compartments open up fine vistas in every direction. In the basement, which is of fire-proof construction, are the store-rooms and heating arrangements. For the accompanying illustration we are indebted to the gentlemen connected with the horticultural department of this, in every way, great undertaking.

ALL bachelors are not entirely lost to the refinement of sentiment, for the following toast was lately given by one of them at a public dinner: "The ladies—Sweetbriars in the garden of life!"

BUILDING FOR THE HORTICULTURAL DEPARTMENT OF THE PHILADELPHIA INTERNATIONAL EXHIBITION.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Beet, Planting out Lettuce, &c.—The principal crop of Beet should now be sown, and, as this is a deep-rooting plant, the ground should be deeply dug and well pulverised. The latter operation is essential for the generality of crops, and for none more so than those that penetrate deeply into the soil, and are of a bulbous or tuberous-rooted character. The seeds of this vegetable, not suffering from the attacks of birds or insects, like many others, do not require sowing so thickly; but sufficient seed must be put in to secure a crop, without having resort to filling up blanks by planting; for, although Beet will succeed when thus treated, yet it entails more trouble; and, in dry localities in a hot season, these plants do not root so freely as some others. Plant out Lettuces that have been sown in the open air as soon as they are large enough to handle; if they are removed to where they are to be grown when the leaves are $1\frac{1}{2}$ inch long, they suffer much less than if allowed to get larger before removal. Upon this, in a great measure, depends their ability to stand long without running to seed; much also depends upon their receiving plenty of water until they have taken a firm hold of the soil. The very slight rainfall that we have had since the commencement of the present year has caused a much drier condition of the ground than usual, and, should this state of things continue, it will soon be necessary in dry places to give water to early Cauliflowers, Cabbages, and autumn-planted Lettuces; where these have been planted on land that has been insufficiently manured, it gives an opportunity for assisting them with manure-water. All amateurs' gardens should be provided with a supply of this, proportionate in quantity to the size of the garden. A brick-and-cement tank sunk in the ground, or a hogshead standing on a few bricks, will last for many years. If horse-droppings are available at a small cost, nothing better is required, a bushel to every twenty gallons of water being used; if a couple of spadefuls of soot be added to a hogshead of the above, it will much improve its fertilising qualities, as well as destroy any offensive smell. For the same purpose wood ashes in similar quantities can be used. Stir the mixture up two or three times in the course of a few days, but, before employing it, let it settle so as to be quite clear; for, if made use of in a thick muddy state, it forms a crust upon the ground impervious to either rain, sun, or air. If the amateur has to purchase material to make his liquid manure, there is nothing better or cheaper than good guano; a handful of this to every eight or ten gallons of water well stirred up for a few days before use, with a little soot added, will make an excellent fertiliser for all plants that require it. For plants in pots, except such gross feeders as Chrysanthemums, the mixture should be diluted with a fourth more water before it is applied. Guano-water is, perhaps, the least offensive of any liquid manure that is used; but, whatever is employed in this way, should be stored at the further end of the kitchen garden. House slops and the liquid from stables or cowsheds are most valuable for use in this manner; and, if to these a little more soot or charcoal be added, there will not be found anything objectionable in their use. Half a gallon of the liquid mixed with three parts of water to each Cauliflower or Cabbage when in full growth will do more than a considerable quantity of solid manure; it also acts rapidly, the plants getting it when they stand most in need of a stimulant. It may be as well to remind amateurs that all outdoor plants to which manure-water is given will bear it much stronger during showery weather than when it is dry. In applying liquid manure it is a very common practice to pour it right up to the stems of the plants; this is just where it is the least effective, for it should reach the extremities of the roots, and these will generally be found in the greatest numbers midway between the plants as they grow. Hoe and stick Peas as soon as they are large enough, and keep the soil well drawn up to the stems of Cabbages or Cauliflowers, or they may suffer from the wind, especially in exposed situations. As Potatoes make their appearance above ground draw the soil well up to them so as to protect them from the slight frosts that are still liable to occur. Potatoes that are planted at the foot of south walls will be much benefited by an occasional soaking with water.

Flower Garden.—In the south of England many will now have commenced bedding-out, yet it is not well to begin too soon. Bare empty beds are unsightly enough, and if they have been in this condition since their last summer occupants were removed, the desire to alter their appearance is not to be wondered at. This, and a few hot days, frequently tempt people to bed-out too soon, but we generally experience some cold nights about the middle of the month, and their effects upon bedding plants, if they do not destroy them outright, are to induce that hard stunted condition which it takes some little time to alter, whereas, if planting out had been delayed for a week, the plants would have grown away without any stoppage. Calceolarias being much less susceptible to injury from a

low temperature than most other bedding plants, may be put out at once. Of late years these have gone off in dry weather to such an extent as to deter many from planting them. It should be borne in mind that bedding plants of most kinds, from the rapidity of their growth, and from being so closely planted, are a most exhaustive crop, and, in a few years, impoverish the soil very much, a condition not entirely remedied by the use of manure, which is not nearly so effectual as the partial or complete removal of the soil in the beds. Calceolarias are almost indispensable in a modern flower garden, as no other yellow flower has been found to approach them in effect. Where a difficulty has been found in growing them, I recommend, if the soil they are to occupy be old, that it should be renewed, and plenty of manure added; when they are being put out make the holes large enough to allow the surface roots to be covered an inch. When the work is completed they should be thoroughly soaked with water at the time, and should never, through the whole season, be allowed to become dry. To accomplish this it is well to leave a shallow basin round each plant, otherwise, after water has been given two or three times, the surface becomes baked, and it runs off to the sides of the beds. A slight mulching of well-rotted dung is also of value. If these directions were followed, especially as regards a good supply of water, we should hear less of Calceolarias going off. Where the beds are filled with spring flowering plants, it often seems a ruthless proceeding to remove many of them, particularly such kinds as red and white Daisies, that are usually at their best just as the summer plants require their room. The present late season will make this more apparent; and, to meet this difficulty, those plants that are to occupy the beds, may, for the present, be removed into larger pots, where their development will still proceed, and the spring occupants of the beds may, for a short time, be left undisturbed. These extra-sized plants will furnish the ground at once. As the spring subjects are removed to the reserve ground, no delay should take place by keeping them out of the ground longer than necessary; and they should be plentifully supplied with water, until established. The result of inattention to these matters will be apparent in the condition of the plants in the autumn. Where the stock of any plant is deficient, or the plants are getting too large, they may be increased or divided as required. Attend well to the different plants that will be bedded out shortly, especially to the various kinds of sub-tropical plants; for, although these and the more tender subjects used in carpet arrangements will not be put out until the beginning of the next month, yet upon their thorough preparation, in a great measure, depends their well-being when exposed to the open air.

Herbaceous Borders, Lawns, &c.—Borders will now be very attractive; keep their surface quite free from weeds, and in an even condition. Never resort to the objectionable practice of tying the leaves of Crocuses in knots; it prevents their being properly matured; for they suffer from the want of light and air when so treated. Their appearance is also much better loose in their natural way than so bunched up. See that everything that requires them has supports before being injured with the wind. Any of the more tender annuals that are to be sown in the open ground should now be put in. If dry, water the soil well previous to sowing. Keep the Grass regularly, but not too closely, mown, so as to preserve an even green surface. Such weeds as Dandelions and Plantains may be destroyed by persistent cutting below the collar. Weeds on walks should, as soon as visible, be removed, thus maintaining perfect order, and the work will in the end be less heavy.

Pits and Frames.—Tomatoes that were sown early should not be allowed to become pot-bound and stunted; where they require it they ought to have more root room. A slight hotbed should be made on which to plant out Vegetable Marrows, using a small frame, or a hand-light or two; a very little heat will suffice to give them the start they require. Give them sufficient water and shade for a few days if the weather is bright until the roots lay hold of the new soil.

Houses.—Peaches that have been brought on in houses by sun-heat, with only sufficient fire to exclude frost on cold nights, will now be swelling their fruit. Thin them sufficiently, but not too much, leaving enough to supply the place of such as may fall in stoning. Disbud gradually, but by no means let this operation be carried too far or remove too many leaves at a time. We frequently see trees so denuded of their foliage by this disbudding as to give both the trees and the crop they are bearing a serious check, for it should always be remembered that the roots receive a check corresponding to the proportion of leaves removed. Syringe the trees every afternoon sufficiently early to allow the leaves to get dry before nightfall, but care must be taken not to close the house too soon in sunny weather, and also to give air early enough in the mornings to prevent the temperature getting too high—70° without air is enough. If the

temperature ever gets too high until after the stoning process has taken place the chances are that the fruit will fall off. Give plenty of water to the roots; no fruit we cultivate under glass or in the open air suffers so often through insufficiency of root-moisture as the Peach.

Flower Garden and Pleasure Ground.

The quantity of bedding plants required in most garden establishments is often greatly in excess of the space that can be afforded for their accommodation, and much difficulty is frequently experienced about the present time in finding even standing room for them under glass; but well-established plants of various species may now be placed in the open air in sheltered positions, where they can have the temporary protection of a covering of mats, frigi domo, or canvas when required. This will be found sufficient for such species as the Verbena, Petunia, Lobelia, Calceolaria, Zonal Pelargonium, and the tall-growing variety of the Ageratum, &c.; while the dwarf variety or Imperial Dwarf, an exceedingly useful plant, but less hardy than its tall congener, should still be retained under glass, as should also Heliotropes, Iresines, Coleuses, Tricolor and variegated Pelargoniums, &c., while the propagation of the various Alternantheras may still be proceeded with unless the stock of these plants already rooted is considered to be sufficient; but, if this is not the case, they will all be found to root more freely now than earlier in the season. Many annuals which have been raised under glass, and which may have been pricked into seed-pans, boxes, or frames, will now be ready for planting out where they are intended to flower; and advantage should be taken of showery weather for the performance of this operation. The plants should afterwards be well attended to, with water during dry weather, until they become well established in the soil. Annuals, which may have been sown in the open air, where they are intended to flower, will now require to be carefully thinned out, and the surplus plants may, if required, be planted elsewhere, and will generally be found to succeed as well as those left where they were sown. Even Mignonette, which is not considered to transplant well, will, nevertheless, succeed, if carefully attended to with water. The finest line of this plant that I can recollect having seen was composed of the new variety, Victoria, every plant of which had been so treated. All climbing or tall-growing annuals, such as the various kinds of Sweet Peas, Convolvuluses, Tropæolums, &c., should be staked as soon as they are a few inches in height. Early flowering Tulips have seldom been finer than they have been this season, and they, together with several other spring flowering plants, are still in considerable beauty; and this year it will be necessary to remove many of them before this has quite disappeared. The reserve ground should, therefore, now be got in readiness for their reception, and the transferring of such plants to this situation, should, if possible, be accomplished during showery or cloudy weather, in order that the plants removed may receive as little check as possible. Many of the plants used in carpet bedding are nearly hardy, such as the Echeveria secunda glauca, Sempervivums, Sedums, the Golden Feather Pyrethrum, Stellaria graminea aurea, and others; and, wherever the beds intended to be planted in this style are at liberty, the soil of the same should at once be properly prepared, and the intended patterns should be sketched out, the marginal and divisional lines planted, and the spaces for tender species left to be filled in, when this can be done with safety. As a rule, flowering plants should be excluded from this style of planting, and the many fine foliaged species, which are best suited for this purpose, have a considerable advantage over flowering plants, inasmuch as no amount of rainfall is likely to be injurious to them, but tends rather to enhance their beauty. Stake, where necessary, and attend to the wants of, herbaceous plants of all kinds, and frequently stir the surface of the soil, keeping it entirely free from weeds. Attend also to beds of Roses, which about this time are likely to be attacked by aphides and caterpillars. The latter must be carefully picked off by the hand, or crushed by a gentle pressure of the young foliage upon which they are feeding; and the plants can be freed from aphids or green-fly by being well dusted with Pooley's tobacco-powder during calm evenings, and should be well washed with the syringe or garden-engine on the following morning; or the plants may be kept clean by repeated syringings with diluted tobacco-water. Continue to extract Plantains, and other weeds, from lawns and Grass verges, and mow the same as often as this may be found to be necessary. Much of the ultimate beauty of the lawn, &c., depends upon getting it into good condition at an early period of the season. Keep gravel walks free from weeds, and take every advantage of the gravel being soft from recent falls of rain, to pass the garden roller over their surface. Attend also to the watering and mulching of all recently transplanted trees and shrubs. While the weather continues dry, and wherever it is found necessary, let

them be securely staked, to prevent them from being loosened in the soil by the action of the wind.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Orchids.

The greater part of the East Indian Orchids will now require to be plentifully supplied with water, and those that have not been potted should have a top-dressing of fresh Sphagnum Moss, which should be allowed to grow over the surface; if it does not keep healthy by regularly watering, then we must expect the soil to have become sour, while, if the Sphagnum grows freely, we may conclude that it is fresh and sweet. Aërides, Vandas, Saccolabiums, and Phalænopsis will be rooting freely this month; to keep the wants of these plants properly supplied, a greater amount of moisture will be required than heretofore, and an atmosphere of 70° should be maintained by night and 85° by day with sun-heat. Plants on blocks will require syringing twice a day, and such plants as are suspended will require daily attention; of Calanthe Veitchii and vestita, varieties that are growing should have a place in the East Indian-house, or a warm Vinery, and be moderately supplied with water at the root till the formation of the bulb commences to show itself, syringing slightly over their leaves. Growing Dendrobiums require a warm moist atmosphere, for, if placed in too dry an atmosphere, they become infested with red spider and thrips. The greater portion of the Cattleyas, will be making roots, and will require great care in watering, for, if supplied too freely when very young, they are apt to damp off; the temperature should be 65° at night and 75° by day with sun-heat. Lycastes that require potting should be looked to or top-dressed according to circumstances. Plants of Coelogyne cristata will be beginning to grow, and therefore they must not be syringed, but supplied with water through a small water-pot between the bulbs, so as not to allow any to lodge in the young growths. Miltonias, Epidendrum vitellinum, and Barkerias, should now be supplied with large quantities of water. Pleiones growing freely should receive liquid manure twice a week, and their leaves should be syringed twice a day. A larger amount of moisture will be needed in the Odontoglossum-house, which should be thickly shaded on very bright days. Oncidium macranthum will be growing freely this month, and should be kept saturated with water, and placed at the coolest end of the Odontoglossum-house to grow. Disa grandiflora should receive liquid manure twice a week, and should be saturated with water while growing. Masdevallias should also be kept very moist at the root and thickly shaded from the sun, and they should have an Odontoglossum-house temperature. Orchid-houses will now be gay with Cattleyas, Cypripediums, Odontoglossums, Masdevallias, Aërides, Saccolabiums, Brassias, Sobralias, Phalænopsis, Dendrobiums, and others.—E. CULLEY.

Indoor Fruit Department.

Vines.—Pay great attention to the stopping and tying of shoots in late Vineries; it is much better to pinch growth immediately the bunch is fairly visible, at two joints beyond it, than to allow 2 or 3 feet to be formed before stopping. Great care is needed in tying down tender shoots; when pressed beyond their strength they are very liable to break off at the base. Shoots, bearing no bunches, may be stopped at the third joint from the main stem, when several good buds will be formed, some of which may produce something more fertile next season. Lateral growths are quickly produced after the shoots are checked; these should be pinched at the first leaf, and should never be permitted to proceed further than another leaf beyond this. The principal wood of many Vines is frequently suffocated with straggling lateral growths, which preclude air and light, and prevents the ripening of both fruit and wood. Golden Champion and other large berried sorts are sometimes given to cracking or splitting; this evil may be entirely obviated by notching the shoot half through below where the bunch is connected; this modifies the flow of sap, a pressure of which appears to cause the disturbance. The berries or bunches may be thinned out to a greater extent now, and after this time, than they were in the early part of the season, as the berries swell more in the summer than at any other time. The earliest potted amongst young Vines should have made enough roots by this time to feel the benefit of weak applications of liquid manure, which may be given with much benefit at every other watering. Dissolved sheep and cow dung, and guano mixed together or separately, are substantial fertilisers, but it is great waste to give liquid manure when the ball of soil is very dry, as it passes through at the bottom, and runs away without doing any good. Dry soil about all plants should first be moistened with clean water, and there is then every chance of the fertilising property of the liquid manure resting about the roots when applied a short time afterwards.

Pines.—Where a great number of Queens have been started into fruit simultaneously, they will ripen together unless some of them are retarded, in order that they may come in one after the other. A

long succession is best obtained from a batch of this description by removing some of the plants, with the fruit attached, when the latter is not quite half-ripe, into a shaded house or room, with a temperature of about 50°, and where a circulation of dry air is going on. A fruit which would become dead ripe in a close warm stove in a week will not arrive at that state for more than a month when subjected to this treatment. When it is intended to keep the fruit back for a considerable time, removal should take place shortly after colouring has begun. The flavour is seldom deteriorated much through the ripening being retarded.—J. MUIR.

Hardy Fruit.

The prospects of all kinds of fruit could not possibly be better, and we may now feel comparatively safe, but coverings should not yet be finally removed. The foliage and new growths on several kinds of fruit, such as Apricots, Pears, Currants, and Gooseberries, are now large enough to form natural protection for fruit and blossom should sharp frosts occur, and therefore pinching or cutting back the breastwood, as it is called, should be deferred for a time until all danger from frosts is over. Unremitting attention will now be requisite to ward off the attacks of aphides, for, if once these pests get a thorough hold upon the trees, all hopes of fruit that is fit either to be seen or eaten are at an end, and the crop of next year is also endangered. Tobacco powder or snuff, applied through a flour dredger, is the best remedy I know till the fruit is set, but afterwards frequent washing with clear water will keep down all kinds of insects and prove beneficial in a variety of ways. It should be applied with a certain amount of force, as through a syringe, garden-engine, or hose. Keep a sharp look out for grubs on Apricots, and caterpillars on Gooseberry bushes, and as there is no remedy so effectual as hand-picking let it be done at once. Pears, Peaches, and Apricots, that have set their fruit thickly, should be thinned out as soon as it can be seen which fruits are likely to swell best. As to thinning, it is very difficult to give precise directions, for experience alone must teach how thin they ought to be, or how many or much fruit a given tree is capable of bringing to perfection. Quality, rather than quantity should be aimed at in fruit culture; certainly, one large and well-flavoured Pear, Peach, or Apricot is preferable to two small ones, and especially with the two latter kinds, the stones of which are a consideration. When thinning, the guiding principle should be to have each fruit clear of its neighbour, evenly distributed over the tree, and fully exposed to sun, air, and light. Young recently-planted trees will require to have the shoots regulated and pinched, trained, or tied into the form they are to assume; in doing which, care should be exercised to have the tree equally balanced, that the flow of sap may be alike over all parts. Any shoots that manifest a tendency to grow stronger than the rest, may be checked by bending them downwards, and keeping the lateral growths closely pinched off; but weak shoots should be allowed to retain all lateral growths made, at least for a considerable period. Canker and gum are the inevitable consequences of too tight ligatures and injury from nails, or bruises in other ways, all of which should be guarded against. Strawberries have made rapid progress during the last few days, and are now throwing up their flower-stems. If it has not yet been done, a mulching of long litter should be applied to them, for the double purpose of keeping the fruit clean at ripening time and to prevent the too rapid evaporation of moisture. Short Grass, or lawn mowings, so frequently used for this purpose, is most objectionable, as a heavy rain splashes the particles of Grass over the fruit, to say nothing of the labour involved to eradicate the weeds thus sown. Plant out the forced plants as directed in last Calendar.—W. WILDSMITH, *Heckfield*.

ALOE HANBURIANA.

Mr. C. NAUDIN pays the following graceful compliment to the memory of the late Mr. Hanbury in the "Revue Horticole:"

"Cette dédicace est un hommage à la mémoire d'un ami dont la mort, aussi inattendue que prématurée, remplit de deuil l'âme de ceux qui ont vécu dans son intimité. Membre de la Société pharmaceutique, de la Société linéenne de Londres, Daniel Hanbury s'était fait connaître comme botaniste, par ses nombreuses communications, qui avaient principalement pour objet les plantes médicinales. Cet amour des plantes s'alliait naturellement chez lui avec le goût de l'horticulture, et il utilisait au profit de ses études favorites le jardin de son frère, situé à la Mortola, près Menton, sous ce merveilleux climat où tant de végétaux exotiques donnent en quelque sorte la main à ceux des pays tempérés. Bien souvent Daniel Hanbury faisait le voyage de Londres à la Mortola pour visiter les plantes qu'il y avait introduites; mais ses libéralités s'étendaient plus loin, et le modeste jardin d'expériences de Collioure en a eu sa large part. Au

nombre de celles que j'ai reçues de lui se trouve le bel Aloès qui va faire le sujet de cette note. Il est en ce moment dans toute sa beauté, et j'allais faire part de ce succès au généreux donateur lorsque la fatale nouvelle de sa mort m'est arrivée. Depuis plusieurs années, Daniel Hanbury s'occupait avec assiduité d'un grand travail de pharmacologie, travail si considérable qu'il a dû s'associer, dans ces derniers temps, le docteur Flückiger de Strasbourg. Avait-il le pressentiment de sa fin prochaine? Je serais presque disposé à le croire, lorsque je pense que l'année dernière, au moment où tant de botanistes se rendaient à Florence pour assister à la grande Exposition horticole, il m'écrivait que lui aussi aurait volontiers cédé aux sollicitations du docteur Parlatore; mais, ajoutait-il, 'la vie est courte et incertaine, et je sens le besoin d'économiser le temps pour achever mon travail.' Il l'a achevé, néanmoins, il y a quelques mois seulement, et peut-être ce dernier effort a-t-il hâté l'heure fatale. Il a succombé le 24 Mars dernier, à l'âge de quarante-neuf ans, dans sa maison à Clapham Common, près de Londres. C'est un malheur pour la science qu'il cultivait avec intelligence et ardeur, mais il se survivra à lui-même par l'important travail auquel il a consacré sa vie, et par les souvenirs qu'il laisse dans le cœur des nombreux amis qu'il s'était faits par la délicatesse de ses sentiments, sa générosité et l'aménité de son caractère. C'est en 1873, si j'ai bonne mémoire, que j'ai reçu de lui la plante dont il va être question. Ce n'était alors qu'une plantule fraîchement germée, et dont la graine était venue de la Cafrerie, avec cette seule indication: *Aloe foliis rubro marginatis*. Mise en pleine terre, à l'air libre et sans autre abri que le voisinage d'un mur peu élevé, elle a passé deux hivers absolument indemne, quoiqu'elle ait dû éprouver à plusieurs reprises de froids de 2° à 3° au-dessous de zéro. Sa tige, cachée par la rosace des feuilles, n'a guère que 4 à 5 centimètres de hauteur; les feuilles, larges presque comme la main, mais un peu plus longues et très-épaisses, sont embrassantes, ovales-aiguës, inermes, très-lisses, d'une teinte glauque rougeâtre, avec un liseré rouge très-net le long des bords. Du centre de la rosace s'élève une hampe de la grosseur du petit doigt, dressée et ferme, haute de 45 centimètres environ, divisée à sa partie supérieure en nombreux rameaux formant le corymbe, et dont les subdivisions portent plus de cent fleurs pendantes, grandes pour le genre (4 centimètres environ de longueur), tubuleuses, à limbe court et un peu réfléchi, du plus beau rouge corail qui se puisse voir. C'est, au total, une superbe plante, que la facilité de sa culture et sa rusticité relative, autant que sa beauté même, recommandent aux amateurs de plantes grasses. Sa taille peu élevée, jusqu'ici du moins, pourrait en faire une plante de fenêtres et d'appartements, et elle serait prise sur les marchés aux fleurs de Paris. Si elle mûrit des graines, ce qu'on peut espérer dans une saison comme celle à laquelle nous entrons et qui est déjà chaude, je serai heureux de propager, au profit de tous, une plante qui me rappelle des souvenirs à la fois si tristes et si chers."

Cannon Hill Park.—Very extensive alterations are being carried on in this Birmingham Park, at the instigation and through the munificence of Miss Ryland. The dreary stretch of meadow land, which lay at the extremity of the ground on the right, has been thoroughly turned over since last summer, and is now being moulded after Mr. Marnock's pleasing designs. Starting from the boat-house to the right of the refreshment-rooms, and passing on towards the south-western end of the park, we find in the course of construction a large boating-lake, which, when completed, will cover an area of no less than 4½ acres of ground. The excavations were commenced as early as October last, the contract being placed in the hands of Mr. Meston. Up to the present time the work has been vigorously pushed forward, and the heavy labour having for the most part been successfully got through, the finishing touches only are needed to complete a very charming transformation. The lake will be 4 feet in depth, and oblong in shape, with graceful indentations along the shore. It contains three islands, which bedded out with shrubs and summer plants, and enriched with grottos and other artificial embellishments, will be very effective and picturesque.

CARNIVOROUS PLANTS.

What's this I hear,
My Mollie dear,
About the new Carnivora?
Can little plants
Eat bugs and ants,
And gnats and flies,
Why—bless my eyes!
Who is the great discoverer?
Alas 'twould be
Sad news to me,
To hear your own dear Fido, pet,
Had lost his breath

In cruel death,
Because one day
In thoughtless play,
He went too near a Violet!
And yet to die
By blossoms, I
Would call a doom chromatic,
For one might wait
A harder fate
Than have a Rose
End all his woes
In pain called aromatic.

THE KITCHEN GARDEN.

THE WITLOOF.

THROUGH the courtesy of Messrs. Vilmorin-Andrieux and Co., we are enabled to give representations of the Witloof, a new vegetable (described at p. 268), the cultivation of which, as a salad plant,

The Witloof.

appears likely to become extended on the Continent, though it may be some time ere it finds favour amongst English growers. It is a kind of Chicory that is cultivated in Belgium for the leaves, which, when blanched, make an excellent salad, less bitter than the better known Barbe de Capucin, a plant belonging to the same genus, and devoted to the same uses.

EXPERIMENTS WITH SEED POTATOES.

I HAVE spent a good many pounds in testing the new sorts of Potatoes that have been offered to the public during the past ten or fifteen years; and with your permission I will briefly give the results of experiments during the past two or three years.

Extra Early Vermont has been in cultivation for the past three years, side by side with the Early Rose, no difference in soil or culture; the first year, while the Early Rose rotted badly, not one of the Extra Early Vermonts was affected in the least with the disease; the stalks were more thrifty and stocky on the Vermonts, and the Potatoes were fully a week the earliest in getting fully ripe. Two years since I purchased one pound each of the Extra Early Vermont and Compton's Surprise, and from that pound of Early Vermonts I dug four bushels of as fine Potatoes as I had ever dug in my life; and they were much larger than I have ever had the Early Rose grow on my farm; thicker, and not so long as the Early Rose; not an unsound Potato among them, neither were they rotten the next spring when taken from the cellar to plant. This year has been a repetition of the two preceding ones, adding to the proof of its great value. For the past three years they have been decidedly better in quality than the Early Rose, although they very much resemble that variety, and have yielded much better on my land.

Compton's Surprise, the first year, did not equal the Vermonts in yield, but were the best Potato for eating we had seen on our table for years. We ate but few of them, as we wished to keep them for seed; but they were tested at different times till May, and found good at all times. This season they have distanced all competitors in productiveness, and their good quality is not abated. I planted May 16th, on dry sound soil on which corn had grown the year previous; they were fully ripe and fit to dig early in September.

Brownell's Beauty has also been in cultivation two years, my seed being direct from Mr. Brownell. This has done finely, but it has not borne off the palm for productiveness. It is of excellent quality, and I should judge from its great productiveness with other persons that it will prove a success over a wide portion of the country when it is better known. They have all proved successful with me, but Compton's Surprise was the best last year.

The Excelsior has been our table Potato the past five or six years, and it is a first-rate Potato for the table, yields well, is rather late, and some seasons has many small ones. Some years it will yield as well as the Peerless. Three years since I sold a customer a barrel of them, and he reported to me in the fall a crop of 130 bushels of the finest Potatoes he ever saw.

Carpenter's Seedling is a good, productive Potato; looks very like the Early Rose; some praise it very highly for productiveness and table quality, but it is not equal to the Extra Early Vermont either in yield or quality.

Ice Cream.—This Potato has a peculiar growth; the leaf is partially curled like the Hubbard's Curled-leaf Tomato; is of a pale yellowish-green colour, entirely different from anything I ever saw before; the stalk short and stout, having the appearance of Vines growing slowly in a drought, while the sorts alongside, with same soil and culture, grew luxuriantly. This variety ripens in September, yields well, and promises to be extra fine for the table, both in boiling and baking. From a single year's trial in its growth I should say that it will prove a Potato of the first class for the table, as we have tested them frequently since they were put in the cellar and always found them excellent.

Snowflake.—This Potato was sent out by Messrs. B. K. Bliss & Sons last spring, and this fall when I dug them, to say the least, I was very much delighted with them, and when tested, either by being boiled or baked, my admiration for them did not at all decrease; and after numerous trials since, I think if they are not the very best Potato I have, all things considered, they certainly are very hard to beat—so smooth, no rot, and are good yielders. I never get such great yields as some persons do, but try to give all new things a fair chance to produce all they can with good soil and cultivation.

Brownell's Eureka is another aspirant for the highest honours, and in yielding properties will no doubt beat the Snowflake, but it is not as smooth a Potato, and has much ranker vines. It is a first-class Potato in quality, either baked or boiled; but on rich ground has grown the past season with me (alongside of the Snowflake, soil and culture the same) with too many prongs or knobs to look as well as it would if it were smoother. No doubt if grown on a moderately rich soil it would grow much smoother than last year, which was very wet in this section till after the tubers were set. I also had a number of other sorts, five or six from California—but must give them another trial, and if not good in my estimation, I shall not recommend them to the public for trial.—J. TALCOTT, in "Cultivator."

THE LATE PEA CROP.

To have Green Peas as early in the season as possible, and late in autumn, is the aim of the Pea grower who has to keep up a successful supply. Anybody may have Peas in July and August, but to have them in May or early in June, and in October and November, requires a little management. The worst obstacle to a successful late crop is mildew, by which, in dry seasons or soils, it is sometimes quite spoilt. In light sandy soils it is often most difficult to escape this disease; while in heavy moist soils it gives little or no trouble. The best preventives are deep trenching, liberal manuring, mulching, and watering. Sometimes late Peas follow early crops of other vegetables that have come off the ground about midsummer; and, though the ground may be trenched, the soil is often then so dry that the top spit, turned undermost in trenching, never afterwards gets thoroughly moistened, and mildew is produced by the very means taken to prevent it. In such cases, therefore, plenty of moist rotten manure should be added. I generally apply thoroughly decayed leaves and litter from the early Vinery borders, adding, at the same time, a sprinkling of lime or lime scraps. This kind of manure once soaked holds a good deal of moisture in suspension, and is very suitable to Peas. It should be spread thickly on the ground and incorporated with the top spit, and if this be dry, it should get a thorough soaking with water when turned in to the bottom of the trench; being immediately covered with the layer of wet soil, the moisture will then be preserved for a time. Of course it is not this watering which saves the Peas altogether, but if it was not given it would be very difficult to soak the soil afterwards. The time to sow depends a good deal upon the variety and the locality. Tall Wrinkled Marrows require from sixteen to eighteen weeks, from the period of sowing till the pods are fit to gather. Here, in a late district, the late crop is always in the ground by the middle of May; it should never be delayed longer. The varieties are generally Veitch's Perfection, Ne Plus Ultra or Payne's Conqueror, and British Queen. The first gathering is ready about the second week in September, but the two last-named kinds often afford gatherings well into November if early frosts do not occur. Much depends upon the season, however, and if we have room to spare, a few more rows of British Queen and Ne Plus Ultra are put in about the end of May; but the crop from this sowing is precarious. Of course, some of the early Marrow sorts may be sown later than this; but none of these are very prolific, and I rather prefer the usual late kinds for the last crop. I have sometimes sown the early Round varieties, such as Auvergne, First Crop, &c.; but they are not appreciated after the Marrows, as they are apt to ripen off suddenly in autumn, and are not to be depended upon. The Marrows are best, and must be sown according to locality. Six feet for such as Veitch's Perfection, and 8 or 9 feet for the latest sorts, should be allowed between the rows; and, to resist the autumn hurricanes, they must be stoutly staked, and afterwards the rows should be well mulched with short Grass or rotten litter, spreading it out 18 inches or 2 feet on each side of the row. If this is done, an occasional watering, if liberal, will serve for a good while; whereas, watering without mulching, in dry summer weather, is of little avail in the case of Peas; for the amount of moisture they absorb in dry weather is prodigious. They are gross feeders and drinkers, as is shown by the state of the soil where Peas have been growing, which is always impoverished and dry. The body of haulm itself on a Pea-row is almost impervious to rain, as anyone may observe; for, after the heaviest showers, the soil in the vicinity of the roots is generally dry, the rain having been thrown off. This dryness at the root, in addition to causing mildew, checks growth, some Peas ripen, while others form slowly, or not at all, and they are never fine-flavoured. I have seen an altogether fresh set of flowers put forth, and young pods form, after a good drenching of rain in October, when this after-growth had apparently come to a standstill. August and September are, however, the months in which abundant waterings are most needed; for the Peas are then about to flower or pod, and just at the stage when keeping the plants in a succulent growing condition is important for the sake of a good crop, and its continuance, which may also be promoted by picking the Peas as fast as they become ready for use, and leaving none to ripen for seed.—"Field."

A TOMATO FOR COLD COUNTRIES.

THE Conqueror is said to be one of the earliest, as well as one of the most productive varieties, in cultivation. In 1869, Mr. Pringle, of Vermont, relying on the opportunity which his residence in the extreme north affords him for the production of very early varieties of plants, set himself to the task of advancing, if possible, the season of maturity of the Tomato, and to the originating of a variety which, even in high latitudes, should produce a crop of ripe fruit before the season of frosts, and which might in more favoured regions

fill a place not occupied by the earliest. Cognisant of a well-ascertained fact in hybridisation, that from the union of two early varieties may issue some which will excel either parent form in earliness, he cross-fertilised the Keyes with pollen of the General Grant. Among the numerous sorts which he raised the next year from this cross, a few gave promise of being earlier than the earliest. A careful process of selection was employed, by means of which the earliest and best of these many shifting forms was seized and given fixedness of character. The fruit of the Conqueror does not remain green for a long time after it has reached its full size, but begins at once to ripen; in this manner it obtains an earliness of maturity which has been some two weeks in advance of the General Grant, and considerably in advance of any of the popular sorts, which have been heretofore considered the earliest, by the side of which it has been tested. This earliness ensures the ripening of the entire crop; which fact, taken in connection with its remarkable productiveness, makes its yield enormous. The habit of the vine is moderately compact. The leaf resembles that of the pollen parent, General Grant, rather than that of the Keyes, on which the seed was borne, and shows much of the curl peculiar to early varieties. The fruit is borne in clusters of eight to twelve, which ripen very nearly at the same time, is of good size, 3 to 4 inches in diameter, round and flattened in outline, uniform in shape and size, and unusually free from irregular or ribbed and crumpled specimens. Its colour is a deep red, minutely dusted with gold. Its flesh is solid, of uniform excellence throughout, of rich, mild flavour. It ripens well up to the stem and is exempt from cracking. Dr. Thurber says "I had over a dozen varieties, including this, among which were several novelties, as well as those accepted as standard varieties. All were treated precisely alike, from the time of sowing to that of fruiting. I think it a moderate statement to say that the Conqueror was ten days earlier than any other in the garden. By earliness I do not refer to the ripening of a single specimen, for the Conqueror ripened one fruit unusually early, but I mean that plants of this would afford a good table supply at least ten days before those or any other variety. I would also add, that in colour, shape, and quality, this variety was highly satisfactory." Seed of this kind is offered in the catalogue of Messrs. B. K. Bliss and Sons, of New York. Dr. Haskins, of Newport, Vermont, says it is "the only Tomato which we have ever planted in Vermont, that has ripened the whole crop and died before the frost." This variety would seem to offer peculiar advantages for open-air culture in England, and we hope it may soon be extensively tried.

Dwarf French Beans.—To have a plentiful supply of these with as little labour as possible, dwarf kinds, which can be grown without the aid of stakes, are the best for all classes of cultivators to grow. Among a number of kinds I have grown for trial I have found none to equal Osborn's Forcing. About 300 pots of various kinds were in full fruiting on April 24, and Osborn's is distancing all the others. Newington Wonder is one which I have grown for many years, and it always gives capital returns, being perhaps the easiest managed Bean in cultivation; and, where a French cook has to turn the produce to account, not only to gratify the palate but to please the eye, he is invariably glad to have such handsome and tender Beans as Newington Wonder at his disposal. Sion House is also one of the best for forcing. I was induced to give Canadian Wonder a fair trial after hearing so much of it, but more especially from seeing it grown to perfection by Mr. Gilbert at Burghley, last year. I have grown it largely, but I have either not treated it skilfully, or may not have secured the true kind.—W. TEMPLE.

Grafting Cabbages.—In reference to this subject (see p. 190), allow me to say that the grafts were placed, some on autumn-planted stocks, and some on early spring-planted ones, the tops of which were cut off level, or nearly so, with the ground; after which the soil was removed, leaving bare that most woody portion of the stem, on which the graft was placed whip-fashion, and simply tied firmly and closely with common bast, so as to exclude air, &c.; the soil was then replaced, at the same time pressed firmly, and allowed to rise slightly above the upper point of contact. As each graft was completed, a 7-inch or 8-inch pot was placed over it, on the drainage hole of which a piece of slate was laid during the middle of the day, the principal object of which was to prevent undue evaporation until the grafts showed unmistakable symptoms of being united, after which the pots were dispensed with altogether. As growth progressed, the pots were, by degrees, elevated from the ground, and a freer circulation of air and light about the plants was allowed. After a few days they were taken off entirely during the morning and afternoon, and only used to shelter the plants for a few days longer from strong sunshine. The stocks were found to require water now and again, and the grafts received frequent light syringings. Any little trouble that attended this part of the business did not extend far beyond a month. After

the union was completed, I had to remove the soil clear of the lower point of connection, to prevent the very great tendency of the scions to form roots, which I considered would, if allowed to grow, spoil the experiment. As regards cross-fertilisation, I had very little to dread on that score, as the nearest garden to me is separated by at least half a mile of dense wood, and in this garden none of the Cabbage tribe or anything is allowed time to flower; but, so as to make assurance doubly sure, I placed, in bag fashion, securely attached to the stem, a covering of fine white netting, through which no fertilising agent could penetrate; by means of cross-sticks fastened to supporting stakes, the covering was kept from coming in contact with any portion of the inflorescence, and it was drawn, by a running string, closely about the main stem.—C. P. in "Gardeners' Record."

New Sweet Corn, Triumph.—This new and superior variety was originated by Mr. Voorhees, of New Jersey, and is the result of ten years of careful cultivation and the selection of seed stock, with the aim of developing the following points of excellence, which are now combined in this variety, viz.: sweetness, earliness—it being the earliest of all the large varieties, and unsurpassed for its richness, sweetness, and delicacy of flavour, productiveness, size of ear, and white appearance when cooked. It has been cultivated as a market variety for several years (though the seed was not offered for sale until last year), and praised by those who have given it a trial. Professor Thurber says—"A single trial of this variety (The Triumph), convinced us of its great excellence, and we regard it as good in every respect."—"Bliss's Catalogue." [This fine early kind should be worth a trial in this country, in which we hope the excellent vegetable delicacy known as "Green Corn" may some day be popular.]

Sprouting of the Early St. John's Cabbage.—Among the seeds distributed by the Royal Horticultural Society in the spring of last year was a Cabbage called Early St. John's. I sowed the seed the latter end of April; it vegetated freely, and, when the young plants were sufficiently strong, they were placed at once from the seed-bed into an open plot in the garden, where, by the end of August, notwithstanding the dry summer, the plants formed heads very regularly, and a series of white solid Cabbages, not very large (the largest not exceeding 6 inches in diameter), was the result. A more uniform bed of Cabbages it would be difficult to conceive, and the regularity with which the plants all came to perfection at the same time was much admired by those interested in such matters. The Cabbage proved excellent when cooked. There is nothing, perhaps, very unusual in this little history, so far; but a change soon took place, and in this manner. When the bed of Cabbages was just at its best, a long, warm, very dry period was succeeded by much rain and a very growing state of the atmosphere. The sudden impulse given to vegetation by this state of things soon caused the solid heads of the Cabbage to burst, and in a few days a series of smaller, well-shaped, rounded, compact heads were formed from the central axis of growth, closely touching each other, and backed up by the leaves of the original head, which remained green and full of sap. The number of these smaller heads varied from three to six in each Cabbage, and proved equally excellent when cooked as the original heads. I am aware that Cabbages often burst in wet weather and spoil; but here the bursting was rather to the advantage of the grower than otherwise, and the regularity of the process was remarkable.—W. S. SAUNDERS.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

White Broccoli.—In reply to your correspondent (p. 376), I would say that there are not many Broccolis in which the sulphur and brimstone colour does not appear. Two, when true, are as white, I think, as can be found amongst all the Broccolis, viz., Cooling's Matchless and Dilcock's Bride; these, cut before they get exposed to light, never fail to give satisfaction. To-day, I have cut some splendid heads of Leamington Broccoli. It has a grand bold head, but it shows the brimstone colour a little.—N. H. P.

—If your correspondent will try the following varieties of Broccoli, true to name, I think they will leave but little to be desired in the way of colour, especially if he keeps the heads well covered up with foliage:—White Cape, Veitch's Autumn Giant, Snow's Winter White, Early Penzance, Dilcock's Bride, Carter's Champion, and Cattell's Eclipse.—B. CALVERT, *Terlings*.

Hardy Kales.—Belgian journals speak strongly in favour of the dwarf and tall green Curled Kales. The past winter left severe traces in the kitchen garden. Broccoli, Brussels Sprouts, and common Cabbage all suffered, the Curled Kale alone escaping injury. The usual precautions were taken to protect the Broccoli, but they were very much injured nevertheless. Here in England, too, the hardy Kales appear to have been neglected of late, but the trying winter we have experienced should reinstate them in favour to the extent at least of providing a supply in case other things fail.—H.

Asparagus in Old Times.—At Ravenna the Romans cultivated Asparagus with most extraordinary results, the stems weighing three pounds each. The same as to-day, they allowed it to boil but a short time, as it was a favourite expression with Augustus, when he wished a thing accomplished quickly, "Let that be done quicker than you would cook Asparagus." The Roman cooks chose the finest heads of Asparagus and dried them. When wanted for the table, they put them in hot water and boiled them a few minutes, a plan good enough to be followed at the present day.—B.

THE HOUSEHOLD.

SCARLET RUNNERS AND HARICOTS.

THE Scarlet Runner, the Haricot, and the Kidney Bean, in all their varieties, are among the most nutritious of human foods. Prejudice, and prejudice alone, has prevented them from being used in England to the extent they deserve. In France, in Italy, and in Spain, they and the Leguminosæ generally form the staple food of the labouring classes. The amount of sanguigenous and respiratory food contained in seeds of this genus is greater than that contained in the best beef, the proportion being also more equal, and requiring less admixture of other food to make up the balance. Thus, while beef contains only ten parts of sanguigenous to every thirty of respiratory food, Peas, Runners, Beans, and Lentils contain ten of sanguigenous to every twenty-two of respiratory food. An Italian writes, in the "English Mechanic," a plea for the increased use of these vegetables:—Having succeeded in growing our Beans, let us notice the best modes of cooking them. For those gathered green, the ordinary method of slicing them in long strips and boiling till tender is very good. When thus boiled, they may be seasoned in various manners—either being covered with a white sauce of melted butter, or by being slightly fried with chopped Parsley, and a suspicion of bacon; or, lastly, made up into a salad with hot oil and vinegar and a slice of Onion, pepper, salt, other condiments being added at discretion. If, however, the seeds are to be eaten ripe—and, for this purpose, the dwarfs are the best—after having been taken out of the shells, they should be placed in a stoneware jar and just covered with water. To each pint of Haricots or Beans, put two ounces of fat bacon, cut into small squares, along with a small sprig of Sage, and a small Onion chopped fine. Place the jar in a warm oven, and allow the Beans to bake till quite tender, adding warm water from time to time to keep them just covered. The liquor produced by the Beans will be found to be quite as palatable as the broth from the finest shin of beef. Or the dry and shelled Beans may be soaked twelve hours in water, and then boiled till quite tender, strained, and made into a salad while hot, with oil, vinegar, pepper, and salt. To correct any tendency to flatulence, which Beans sometimes produce, a clove of Garlic or a Spanish Onion should be sliced up and mixed with the salad.

MODES OF COOKING RICE IN INDIA.

RICE, the staple food of India, is prepared in numerous styles; among these are the following methods, used by the natives of Bengal:—First, paddy (unhusked Rice) is soaked in cold water twenty-four hours, after which it is dried in the sun, and when sufficiently dry to bear the process, is husked in a treadmill. In the process the grain broken by husking are separated by a fan from the unbroken. Second, the paddy is first soaked in water, then boiled, dried, and husked; different varieties require to be soaked for periods of different length. If the paddy is oversoaked, the Rice is dark-coloured; if overboiled, it is coarse in appearance; if overdried, it is much broken. Third, the paddy is parched. In this process the grain in parting with its moisture swells up to about four diameters, becomes very light and white in appearance, and the husk is split and separated from the desiccated, puffed grain. Fourth, "flattened paddy." This is first boiled well, and then, after being slightly dried, under the pestle of the treadmill is husked and flattened at the same time. Fifth, parched Rice. The husked Rice, being slightly wet with water and salt, is placed on a parching-pan or sand-bath (the latter gives a better flavour to the Rice), and being briskly stirred, it immediately swells to about one and a half diameters, and becomes anhydrous and blistered by the escaping moisture. But if the Rice is cured by boiling the paddy twice before husking, then moistening the husked Rice with salt and water and drying it by fire, it is made to contain sufficient moisture to swell the grain when parched to three or four diameters. The foregoing preparations are all white and light. They are eaten generally with salt, pepper, and mustard-oil. Khai (parched paddy) is specially suited for the sick as a healthful, dry, and light food. Confections are made of it with syrup of sugar, syrup of molasses, a variety of spices and condiments, in various forms. Sixth, boiled Rice, called bhat. This is the principle food of the natives. "A Bengali, however richly fed, does not feel satisfied unless he takes his usual bhat; meat, fishes, soups, dols, curries, and chatnies, however varied and nicely prepared, are aids and secondaries to bhat." The modes of cooking boiled Rice, either alone or in connection with other articles of food, as milk, sugar, and almost every kind of indigenous fruit and vegetable, are too many and diversified to afford room here for description. Rice also enters as an ingredient into a great variety of confections.

A DISAGREEABLE CLIMATE.

SOME of the Ontario newspapers are greatly exercised in connection with a few statistics of Canadian temperature forwarded to you from here by "An Exile." Their argument seems to be that such unpleasant facts should not be "permitted" to transpire, lest they should "stop emigration." You are, however, doing a real service to hundreds of persons at home in giving publicity to facts calculated to dispel the "bamboozlements" of paid agents and lecturers. The true test of a climate is not in mean temperature, but in the range of the thermometer, which rises here to 100° in the summer, and falls to 40° below zero in winter. As for variableness, a man who returns home after several years' experience of Ontario will grumble no more to the day of his death respecting the English climate. Almost every variety of heat, cold, wet, dry, wind, calm, and storm is frequently experienced in a day or two. As to the "dry air," it seems to agree with agents better than with horses. The following is from the "Toronto Globe":—"A horse left tied to a post in Guelph the other day during a cold snap was found frozen to death when its owner returned." According to a telegram in the "Toronto Mail":—"On February 10th a man named Wilson had one of his horses frozen to death in the harness while resting on the side of a hill for a few moments near Acton, Ontario, with a load of lumber." As I have seen at least thirty cases of "freezings to death" in some half-dozen Canadian papers during this winter, with "frost-bites" innumerable, I am led to think the emigration agents in England do not know much about our winter. Permit me to supplement "An Exile's" figures with a few others. Mr. S. C. D. Roper, of Mary Lake, Muskoka, Ontario, has a registering thermometer, of which the account is:—"Feb. 5, 26° below zero; Feb. 6, 15° below zero; Feb. 7, 40° below zero; Feb. 8, 35° below zero; Feb. 9, 37° below zero; Feb. 10, 36° below zero; Feb. 11, 3° below zero; Feb. 12, 20° below zero; Feb. 13, 43° below zero; Feb. 14, 40° below zero; Feb. 15, 30° below zero." In Manitoba, Mr. Stewart, signal observer, reports from Winnipeg the following refreshing figures for January, 1875:—"Mean monthly temperature, 15° below zero; highest temperature during the month, 20°; lowest, 41° below zero; highest wind, 39 miles per hour; Feb. 1, 22° below zero; Feb. 2, 24° below zero; Feb. 3, 30° below zero; Feb. 4, 36° below zero." As I see some gentlemen are about to ask subscriptions at home for a Manitoba Emigration and Investment Company, with the usual "£250,000 capital," &c., I invite attention to the above figures. Permit me to add the readings of the mercury at Ottawa, Ontario, the Legislative capital, for part of January and February, 1875:

Date.	Degs.	Date.	Degs.
Jan. 16 ...	24 below Zero.	Feb. 1 ...	0 Zero.
" 17 ...	23 "	" 2 ...	5 below Zero.
" 18 ...	15 "	" 3 ...	3 "
" 19 ...	21 "	" 4 ...	18 "
" 20 ...	15 "	" 5 ...	2 "
" 21 ...	5 "	" 6 ...	34 "
" 22 ...	4 "	" 7 ...	32 "
" 23 ...	14 "	" 8 ...	24 "
" 24 ...	3 "	" 9 ...	23 "
" 25 ...	18 "	" 10 ...	26 "
" 26 ...	15 "	" 11 ...	18 "
" 27 ...	17 "	" 12 ...	36 "
" 28 ...	20 "	" 13 ...	27 "
" 29 ...	14 "	" 14 ...	22 "
" 30 ...	12 "	" 15 ...	12 "
" 31 ...	0 Zero.	" 16 ...	8 "
		" 17 ...	22 "

The above figures are from the "Ottawa Citizen." It will be seen that on February 10th, the day the horse was frozen to death at Acton, the mercury marked 26° below zero at Mary Lake (Muskoka Free Grants). The sufferings of the families of the thousands of men out of work during our Canadian winters, in the single matter of fuel alone, are dreadful. "A Working Man" writes to the "Globe":—"During the night of January 9th many working men in Toronto, their wives and families, felt more intense suffering from being ill-housed and ill-fed than the wealthy feel in a lifetime." Last month an old man named John Granger, having no other shelter than an old hen-house at Hamilton, had his jaw and face so badly frozen that some of his teeth, though sound, fell from his mouth. The "Hamilton Times" of February 2nd says there are numbers in that city similarly destitute."—"Times."

THE USE OF TAN IN GARDENS.

WRITING in the "Revue Horticole," M. Baltet urges the use of tan in gardens, where, he states, it is most useful for covering the walks, the acidity in the material checking, or, indeed, preventing, the growth of weeds, especially where they have first been cleared away. The paths are likewise rendered more pleasant to walk on than on gravel, or on the scoria and shingle frequently used. Too thick a coating should not be given, as this is likely to harbour damp after rain; but this can be remedied by previously spreading upon the ground

a layer of cinders, upon which the tan will rest, and which will drain off the water rapidly and efficiently. The tan should be renewed upon the walks in the spring, as they are much worn in winter. The old material is scraped off and deposited on the borders, where it forms excellent mulching, and may subsequently be incorporated with the soil as a manure; for Strawberry or Raspberry beds nothing is better. In la Brie the white maggot attacks those plants that are mulched with tan less frequently than any others. On the edge of the footpaths the roots of *Abies excelsa* are fond of developing their spongioles in old tan, for it is left for several years upon the less used walks. Some time back, M. Baltet made the following experiment upon a plot of Asparagus. One part of the bed was covered with tan, the other with saltpetrous earth. In the latter portion growth was very vigorous, whilst in the former it was the reverse. Tan, therefore, it may be presumed, is not conducive to the health of Asparagus. An accidental circumstance also showed that a young tree, having its roots dried up or weakened by a long journey, will recover and even throw out young rootlets when the roots have been placed in a heap of tan. An arboriculturist of Troyes, M. Lanier, wishing to re-invigorate an espalier of Pear trees, used a mulching of dung, but being deficient of a proper quantity, he tried fresh tan; and all those trees to which the latter was applied assumed a robust aspect, whilst the others remained unhealthy. M. Baltet states, that he still uses tan in hot-bed frames, mixing it with a bed of earth, and that the kitchen gardeners use it to fill up the paths between the beds; later on, this tan is mixed with dung. At Saint Hubert, in Belgium, gardeners make a good thing out of the heaps of tan from the tanneries; and it seems probable that more will be heard of this vegetable substance.

ZINC GARDEN LABELS.

AFTER trying lead and various other sorts of labels for garden borders, I have found the kind here figured and described the most

satisfactory, as they are absolutely imperishable, and the numbers cannot be effaced; moreover, they do not bend with any slight pressure as leaden ones do. They are made of zinc, are comparatively cheap; and the time occupied in numbering them is short. I find a very convenient size to be 7 inches long, and 2½ inches wide at the upper end. The tools for cutting the numbers are a mallet, a chisel, for the longer strokes, five-eighths of an-inch, and for the shorter one, half-an-inch wide—these should be bevelled on both sides to bring them to a very sharp wedge shape—a bradawl, ground down to form a punch for the circular holes, and a block of wood, on which the labels are placed while cutting the numbers, completes the necessary apparatus. The numbers I use, which are the only ones suitable for this plan, are those first published, I believe, by the late Mr. Loudon; they are easily learnt by anyone, and soon become as

familiar as any other kind of figures; they should be cut quite through the metal.

J. G. N.

I have read Mr. Latimer Clarke's account of his label machine (see p. 315) with interest, and have no doubt that it will answer admirably. But why incur expense, when as good a plan, and one more easily applied, is at hand. I use some thousands of labels in the course of a year, and find that, for ordinary work, zinc labels, with the name bitten in with acid, answer admirably. I make my own labels, and, of course, can manufacture them more cheaply than if I bought them; but, for amateurs, Yeats' labels are all that can be desired. Obtain a shilling bottle of stopping-out varnish from Buck's, or Fenn's, in Newgate Street, a sufficient quantity of labels, some spirits of turpentine, a slate pencil, some pieces of rag or sponge, and some spirits of salts; just touch the face of the label with the acid, wipe it clean, and cover with a thin coat of varnish. With the pencil, finely pointed, write the name on the surface thus prepared, taking care to remove all varnish where the acid is to bite—as otherwise no mark would be made; then pour a few drops of acid on the writing, and let it lie for about five minutes. The acid should then be wiped off with a piece of rag, and the varnish removed with a sponge or rag, saturated with turpentine, when the operation is complete. Labels thus made cost, after they are written, about 3s. 6d. per 1,000, and will last good for nine or ten years.

WALTER J. MAY.

2, Beethoven Street, Kilburn.

THE FLOWER GARDEN.

WINTER ROSES IN THE UNITED STATES.

THE winter production of Rose buds, in the United States, as a commercial enterprise, is a branch of floriculture that has now assumed large proportions, the buds realising from £1 to £1 12s. per hundred. The method of production about New York varies much amongst the numerous growers, some planting out, whilst others prefer growing their Roses in Pots; and the latter is, I think, the preferable plan, as you then have the plants more completely under your control. When planted out, they cannot be rested during the summer months; but, when grown in pots, they can be taken out of doors by the middle of June, rested for a couple of months, and their balls partially reduced. The weak wood is thinned out, and the leaders cut back. The planting-out system may succeed for some years, but eventually the soil becomes exhausted; the buds are only half developed, and the market value is correspondingly diminished. The following is found to be an excellent plan for Rose-cultivation in pots. The cuttings are struck in January, and potted in a 2-inch pot. By March 1st they should be shifted into 4-inch pots, and into 6-inch pots as soon as these are filled. This will be the case about the middle of May, when a hotbed 4-feet deep is made, and on this is placed 6 inches of coal-ashes, in which the pots are plunged to the rim; pure water and liquid manure are given alternately—for the latter, I find superphosphate the best. As their roots are found to fill the pots, the plants are shifted on, and not a single bud is allowed to develop; but they are all pinched off when they are the size of Peas. Upon the prompt removal of the buds depends, in a great measure, your success. If the plants be well-grown, they will occupy 10 and 12-inch pots by October 1, and should be removed to the greenhouse by the 20th of the same month, when they may be allowed to flower. A temperature at night of from 65° to 70° should be maintained, and an abundance of moisture given. Every evening the syringe may be used freely, and the paths should be flooded with water. The method here described is superior to that of planting out. It produces larger buds, and permits the annual renewal of the soil being effected, which is a matter of consideration in Rose culture.

JOHN HOWATT.

Plants Hardy in Gloucestershire.—I think we may now venture to reckon up the gains and losses of the past winter, which I consider to have been one of the most trying that we have had for many years. I therefore send a list of plants of whose hardiness I was doubtful, with the results of the winter upon them. All have been unprotected. The following, I fear, are dead:

Yucca filifera concava Eucalyptus obliqua amygdalina corynocalyx Callitris cupressiformis	Convolvulus Cneorum Statice echioides Salvia taraxacifolia Fuchsia Dominiana	Boykinia occidentalis Modiola geranioides Cheiranthus mutabilis Hypericum balearicum	Heuchera himalayensis Erigeron glaucum Solanum jasminoides (in the open border)
---	---	---	---

The following are all alive, though some of them have been more or less injured:

Yucca aloifolia varie- gata Ruscus androgynus Teucrium fruticans Lycium purpureum Edwardsia microphylla Solanum jasminoides (against a wall) Richardia aethiopica Phormium tenax Cneorum tricoccum Mandevilla suaveolens Xiphion Histrio Vallota purpurea Umbilicus Libanotis	Pterostyrax hispidulum Mutisia decurrens Iris fimbriata Pelargonium Endlicherianum Cyclobotrya pulchella Veronica Hulkeana Pistacia Lentiscus Clerodendron Bungei Vitex Agnus-castus Arisarum vulgare Leuzea conifera Polygonum filiforme Philesia buxifolia	Callirhoe involuta Orchis foliosa Tritonia aurea Tulbaghia alliacea Habranthus pratensis Tricyrtis macropoda Saxifraga Fortunei mutata Cyrtomium Fortunei Margaritacarpus setosus Geum capense Lastrea atrata Psoralea Pourcei Kniphofia caulescens	Eccremocarpus scaber Pentstemon Palmeri Phlox pilosa Diplacus glutinosus Hypericum Coris Rubus australis Globularia nana Bellium minutum Bellis rotundifolium ceruleus Eupatorium ageratoides Eulalia japonica Brugmansia sanguinea Geranium tuberosum
--	---	---	--

In this list I should like to draw special attention to *Mutisia decurrens*. My plant was a small one, and I was very doubtful about leaving it out; but the winter has not only had no bad effect upon it, but the plant has been actually growing slowly but steadily

all the winter, so that it has now shoots of this year's growth of more than 8 inches. The plant may, therefore, be highly recommended as a hardy climber. Its flowers are very handsome, and its leaves very curious; their shape is very quaint, and each leaf is terminated by a long double tendril. I am so much pleased with the plant that I would try the beautiful *M. ilicifolia* if I could meet with it, but I fear it is very scarce. There are many plants that have not yet sufficiently declared themselves to be placed in either of the above lists; but I can send you a supplemental list if you so wish. I hope others will send you similar lists.—H. N. ELLACOMBE, in "Gardeners' Chronicle."

Culture of Clematises.—Where it can be provided, a rich soil of a light loamy character is the best for Clematises; and if this be mixed, either naturally or artificially, with chalk or lime, so much the better. Thorough drainage is indispensable to good healthy development, and the vigour of the plants must be kept up by at least annual manurings with horse or cow manure. On dry hot soils, cow manure would probably be best; while, on heavy soils, a thorough dressing of good leaf-mould would be beneficial. Mulching with half-rotten dung, on the approach of winter, also tends to increase both the strength of the plants and the size of the flowers. Pruning must likewise receive attention. The varieties belonging to the *Montana*, *Patens*, *Florida*, and *Lanuginosa* types, should be pruned in February or March, when all weak, straggling, or overcrowded branches should be removed. In some of these types, the plants flower from the old or ripened wood; therefore, to secure blossoms, the strong one-year-old wood should be trained in, as far as it has become thoroughly ripened, beyond which it may be cut away, the parts retained being so disposed as to fill up all vacant spaces. The varieties of the *Viticella* and *Jackmani* types are mostly large-flowered summer and autumn bloomers, flowering on the young or summer shoots. In pruning these, the aim should, therefore, be to favour to the utmost the development of vigorous young shoots, and this is effected by cutting the summer growth back each season, as soon as the frosts have disfigured the plants, say in November, to within about 6 inches of the soil.—G. JACKMAN.

Spring-planted Bulbs.—It is generally considered an absolute necessity that all bulbs should be in the ground by the end of October, at the very latest, in order to ensure a perfect display of bloom the following spring. It is difficult, however, to see in what way bulbs are benefited by lying in the cold, damp, and often frozen, ground for three months; for, unless in exceptionally mild winters, no growth is seen above ground until February; therefore, whether such bulbs would not be better in their paper bags in some comfortable place, and planted out about the time they will at once start into growth, is a matter for consideration. I saw a considerable number of Hyacinths, Tulips, and Crocuses on the 1st of February last, the bulbs of which were not of a very superior quality—in fact, had they been planted in October, I should have expected 50 per cent. of them to have decayed in the ground before the end of January; as it was, not one failed. The Crocuses were the first to appear above ground, then the Hyacinths, and finally the Tulips. The Crocuses have been out of bloom for some time. The Hyacinths have been in perfection for the last four weeks, and still present a fine appearance, some of the bulbs bearing two spikes, which, in some cases, are furnished with as many as fifty blossoms. Many of the Tulips are in bloom, and other later kinds bear good indication of a fine display by-and-bye.—J. MUIR.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Geranium Willsi roseum for Vases.—If a little pains is bestowed in tying down and training, these make showy little specimens for drawing-room vases. I have a few now in the room, which are in a blaze of bloom, literally hiding the vases they are in. I can think of no flower which is more pleasing in colour.—J. P. T., *Killruddery*.

Culture of the Flame Nasturtium (*Tropæolum speciosum*).—As I have been told that this *Tropæolum* never does well except in Scotland, I am anxious to know whether it will grow well out of doors in the south of England, what aspect suits it best, and whether a low terrace wall facing due south would be too hot for it.—L. R.

White Camellia out of doors at Bournemouth.—Referring to the note on this subject in the last number of *THE GARDEN*, I may state that there is a very remarkable specimen blooming in the open air at Bournemouth. It grows in the garden in front of Morley House, opposite the Bath Hotel. It is at least 9 feet high and 10 feet through, and during the past spring bore innumerable perfect flowers, in some cases four or five together. It is well sheltered from the north and east by the house wall, and otherwise by shrubs.—JOHN BAIN.

Hardiness of Acacia Nemu.—This has withstood unprotected the test of this severe winter here. We once had (1st of January) the thermometer down to zero; then fine warm weather for several weeks, and afterwards (Feb. 11th) 4° of frost, but neither freezing nor thawing has affected this *Acacia*, the graceful foliage of which gives quite an exotic aspect to the group of plants in or near which it may be planted. It has now been growing here three years in the open air, as a single specimen, and I expect to see it flower this season. It is a fast-growing and handsome plant.—MAX LEICHTLIN, *Baden Baden*.

SOME CALIFORNIAN FLOWERS.

ONE of the most beautiful floral exhibitions we ever beheld, was on the road from Murphy's Camp to the Calaveras Grove. This was about five acres of *Nemophila* in full bloom, making a more compact and beautiful mass than we have ever seen this flower produce, either in Europe or America. On approaching the Grove we saw something that startled us. Near the line of snow—for snow still lingered in the shady places and dells, where it had become piled up during winter storms, we observed several crimson spikes growing from the moist soil. We left the carriage in a hurry, and knelt in wonder and delight before the beautiful Snow Plant, *Sarcodes sanguinea*. This is a parasitic plant, growing on the roots usually of Pine trees. The stem is succulent, all above ground being rosy-crimson, while the portion not exposed to the light is pale pink. The usual height is from 1 foot to 18 inches, but the last number of the "California Horticulturist" describes one recently found near where we first saw them, 28 inches in length, the spike of flowers over 13 inches, and bearing ninety-eight blossoms. The Snow Plant is plentiful in the Sierras.

Bolander's Catchfly Pink (*Silene Bolanderi*) is one of the prettiest wild flowers the tourist will meet with on his travels. The flowers are of the most delicate pink imaginable. When we first saw them in bloom while driving along rapidly in the coach, our first impression was that we had found a new *Lychnis*, after the style of the best cultivated sorts, like *Haageana*; then we thought it must be a Japan Pink, somewhat after the style of *D. laciniatus*. Dr. Kellogg informs us that it was only recently discovered, and considers it a match for the finest Japanese Pinks.

Ithuriel's Spear (*Triteleia laxa*).—This plant resembles the *Agapanthus*, and improves wonderfully by cultivation. It bears a large cluster of flowers, often as many as fifty. The colour varies from Victoria blue to purplish-blue, according to soil, exposure, &c.

Celestial Star Tulip (*Calochortus coerulea*) is a pretty little bulbous plant, light blue, mottled with purple. It has not been cultivated to any extent, we think.

White Tea Tree, or Mountain Birch (*Ceanothus integrifolius*).—The mountains about the Yosemite abound in this beautiful Lilac-looking shrub. Imagine, if possible, that you are on a road out in the mountain side, with a thousand feet of the mountain below, and quite as much above you, and all this, as far as the eye can reach, almost literally covered with white Lilac bushes in full bloom, and you will have something of an idea of what we saw and enjoyed one day, when to relieve the tired and over-burdened horses, we climbed four miles of mountain road. The Mountain Birch abounds in the Yosemite, and many or most parts of the middle Sierra Nevada Mountains.

Twining Hyacinth (*Brodiaea californica*).—Of all the pretty flowers that abound in California, we know of nothing prettier than the twining Hyacinth. The flowers are a very fine pink, or deep rose. It grows in the mountains and twines over every bush it can reach, and the flower-stem goes to the top of the bush to which it is attached, no matter if it is 5 or 10 feet. After it gets to the top of the bush and rests awhile, it lets go of the earth, and goes on blooming and seeding for weeks and months, regardless of the burning sun by day, or the cool mountain air by night. The leaves are long, narrow and grass-like. The roots are very deep, and being entangled with roots of shrubs and bushes, it is next to impossible to get them up. This plant is in flower at all times from May to September. The flower-stem breaks off near the ground, and the flowers are left swinging in the air without any connection with earth or root, supported by the bush about which it twines.—"Vick's Guide."

A Florists' Feast Long Ago.—The following copy of the prize list of a flower show, held many years ago, may be interesting to some of your readers—P. G. "To all Gentlemen Florists.—Your company will be esteemed a favour to dine with the Society of Florists, at the Lion and Lamb Inn, in Leicester, on Monday, the 16th day of April, 1787. Ald. Coleman, J. Newbold, stewards.—The following free prizes will be given:—The best and completest *Auricula*, 10s. 6d.; second ditto, 7s. 6d.; third ditto, 5s.; best seedling ditto, 5s. The best *Polyanthus*, 7s. 6d.; second ditto, 5s.; third ditto, 2s. 6d.; best seedling ditto, 2s. 6d. Dinner to be on the table at two o'clock. The flowers to be the produce of each person's own garden, and the seedlings of their own raising, and never shewn before for a prize. N.B.—All florists to leave the blossoms they shew for inspection of ladies and gentlemen of the town the next day: to be seen at the Lion and Lamb. Gentlemen florists who live at a distance from Leicester to be allowed to shew their *Auriculas* in viols."

NOTES AND QUESTIONS—VARIOUS.

Curious Sport of the Flamingo Plant.—A specimen of this in Mr. Gumbleton's collection at Belgrove, Queenstown, has produced a double spathe. If this remains constant, it will prove an important acquisition.—Q.

A Black Bedding Plant (Coleus Hero).—This was employed very largely last year for bedding, and affords a most striking effect in the flower garden. It makes quite a black bed.—T.

The Scotch Bird's-eye Primrose (Primula scotica).—This is a veritable gem, somewhat resembling *P. farinosa* in foliage. It is now in bloom with me, and has a flower-stalk 2 inches in height, surmounted by half-a-dozen pips that are very small, but perfectly formed, and violet-mauve in colour.—A. D.

Fasciated Double-flowered Buttercup.—I have sent you a specimen of a singular monstrosity which has sprung up in my grounds; in the centre of the plant nearly the whole of the flower-stems (which are much more numerous than usual) are flattish; do you think it worth saving?—Wm. RUMSEY. [As an example of fasciation it is one of the most interesting which we have seen; but it is not worth propagating.]

Peach Shoots killed with Oil.—Dr. Masters showed, at a recent meeting of the Scientific Committee, at South Kensington, shoots of Peach trees from a correspondent who, to remove scale from them, had thickly painted them with colza oil, and allowed it to remain while the shoots were exposed to the sun under glass. The result was that the plant was suffocated and the shoots died.

The Labels in St. James's Park.—Are not the labels in this, and other London Parks, absurdly awkward and needlessly large? The popular name, the scientific name, and the country, are all that are really needed. When there is too much written on a label, especially of such alarming phrases as "an Amygdalaceous tree," they are rarely read. Some of the labels to which I allude are more than a foot across the head.—JOHN BAIN.

Pomegranates without Pips.—M. Béreau, who for several years was gardener to the Shah of Persia at Teheran, states (says M. Carrière in the "Revue Horticole") that in that country a variety of the Pomegranate without pips is frequently met with. It is quite as large and handsome as the ordinary kind, and, in one respect is far superior to it, inasmuch as the entire mass is composed of the luscious pulp which in the common sorts is found in such small quantities, its place being occupied by the useless pips.

Canker in Young Apple Trees.—Allow me to tell "A. B." (p. 376) that I should be disposed to drain the land 4 feet deep, or to where the water lies, and lift the trees so as to get their roots more under the influence of sun and air. With only a superficial knowledge of all the circumstances under which the trees are growing, it is difficult for anyone to speak with decision, but I believe this is what should be done. Canker is either from bad food, or a glut of good food badly digested.—N. H. P.

High-priced Stumps.—Some time in March Mr. Roezl, the well-known plant-collector, consigned fifty-two plants of a rare Cycad, *Zamia Roezlii*, from Buenaventura, to Young & Elliott, seedsmen, of New York. To an ordinary observer they looked like pieces of rotten wood, but when Mr. Elliott offered them at an auction, a spirited competition showed that they were "diamonds in the rough," for some of them, according to the "Agriculturist," brought nearly £7 each. Mr. George Such, of South Amboy, was successful in monopolising the rare lot, except one specimen.

Transplanting Wild Flowers.—In moving wild flowers or plants, always transplant in the twilight. On delicate plants, especially forest plants, this operation can be most safely performed after sundown. If there is light enough to affect a sensitive photograph plate, it will affect the equally sensitive points of the roots. If transplanting cannot be done in the evening, choose the afternoon rather than the morning, and a cloudy or rainy day rather than a bright one. The most fragile plants moved or disturbed after sunset and then freely watered, are often as fresh next day as if they had not been touched, although it is well to take the precaution to shade them for a while.—"Cultivator."

Carter's American Breadfruit Potato.—Inquiries are made about this Potato, which is declared to be without a history, and in want of a character. It really has a history, though it has not yet been told, and Messrs. Carter & Co. may choose their own time for telling it. There can be no doubt it is of American origin, though let out here in advance of its becoming known on the other side, and it is not only possible, but highly probable, it will turn out one of the very finest of the American breed. In all its characters it approximates to *Snowflake*; it has beauty and quality, and a good constitution; and it is, moreover, well adapted for field or garden culture.—"Gardener's Magazine."

Broccoli in Succession.—The following kinds, if true to name, would give your correspondent (p. 376) a good succession of compact white heads from November until June:—*Snow's Winter White*, *Veitch's Early White*, *Dilcock's Bride*, and *Cattell's Eclipse*. Some of the latter should be planted on a north border, to make them as late as possible; and should be succeeded by *Walcheren Cauliflower*, which, sown at the end of August or beginning of September, and wintered under hand-lights or frames, would come into use at the end of May and throughout June. These should again be succeeded by *Walcheren* and *Veitch's Autumn Giant*; sown on a slight hot-bed in February, the *Walcheren* would be in throughout July, followed by *Veitch's Giant* through August and September, and both would be succeeded by the same sorts sown early in April, which would last until *Snow's Winter White* came in, thus keeping up a good supply the whole year, unless destroyed by severe frost. I had a splendid lot of *Veitch's Autumn Giant* throughout last August, and kept some in an early Carrot frame.—J. GARLAND, *Killerton, Exeter*.

Spring Flowering Town Trees.—These are just now so very beautiful that one could wish they were more plentiful in town gardens and squares. The blooming season of the common Almond is over. The snow-white double-blossomed Cherry is very beautiful, contrasted with the deep rosy flowers and crimson buds of the double-flowered Peach and the vivid scarlet *Pyrus* (*Cydonia*) *japonica*, *Forsythia viridissima*, rosy and crimson-flowered *Ribes*, *Berberis Darwinii*, and the snowy *Amelanchier vulgaris* are now very effective, as is also the deliciously-perfumed *Magnolia conspicua*, while *Lilacs* and golden *Laburnums* already give promise of a magnificent show. In some suburban gardens the *Rhododendrons* and *Ghent Azaleas* are glowing masses of the most brilliant colouring, always beautiful in fitful sunshine or when bathed in April showers. One of the freshest and most effective of all spring flowering trees, however, is the Norway Maple (*Acer platanoides*), which has been one mass of the most delicate golden-green flowers; and these, at a little distance, so closely resemble the tender young foliage that they might easily be overlooked. The *Montpelier Maple* (*A. monspessulanum*) also bears golden-green flowers, and both are invaluable for landscape effects in spring.—F. W. BURBIDGE.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

GARDEN LABELS.

It may be useful to divide these into three classes, each having a particular purpose of its own to serve. 1. To indicate a tree or plant by a title that any passer-by may read. 2. To enable the proprietor, or his gardener, to distinguish at any moment one plant from another by merely examining the label. 3. To answer a mere temporary purpose, such as would be required for bedding plants and annuals, until they are disposed of in their respective quarters in the flower garden. Of the three classes enumerated, it is the first only that would require the labels to have a neat appearance, as well as to exhibit the name of the plant in clear and legible characters. Painted wood and iron are the materials often used in botanical gardens and parks, while in private collections labels manufactured in terra-cotta, and in cast white metal with raised black letters, are now more commonly met with; the latter, as sent out by Mr. Smith, of Stratford-upon-Avon, and by Mr. Bell, of Eastbourne, seem well adapted to this particular purpose, and are proof against breakage under the most trying circumstances. On the other hand, the terra-cotta labels of Messrs. Maw, Benthall Works, Broseley, though liable to be broken by careless handling, have this advantage over metal labels, that they can be had either with or without the names painted on them. Next in order come those that are made of sheet zinc, and are written on with a pen. No doubt these can be made to look very neat where appearance is an object; but I put them in the second class, because they are especially suited to mark, in an unobtrusive manner, every description of plant and shrub. Perhaps the best way to attach these (and, indeed, most labels that are required to remain for an indefinite period) is to make, with a short piece of galvanised iron wire, a figure of eight, one loop for the label, the other for the tree. These labels are supplied by Messrs. Carter, of Holborn, and many other dealers; and those manufactured by Mr. Yeats, of Mortlake, Surrey, seem to be of the same character. There is also supplied with them a black fluid, which can be used to write the names with an ordinary pen. The following, too, is a good recipe for making ink for zinc labels:—Verdigris, powdered, 1 drachm; Sal ammoniac, 1 drachm; lamp-black, $\frac{1}{2}$ drachm; water, 10 drachms; the whole well mixed, and shaken before using. I have by me some labels, with names written on them with this ink five-and-twenty years ago, and they are still legible. I have even dug them up uninjured, when they have laid in the ground more than a year. Anyone who possesses a pair of metal shears and a common punch can make these labels for himself out of refuse sheet zinc, which can be had of any ironmonger at less than half the cost of large pieces. I have lately met with a new label made of soft metal, with the name of the tree stamped on it. It is unobtrusive, and, at the same time, not unsightly; and is secured to the tree by simply twisting round it the upper or blank end. It can be attached by the most delicate fingers, and would not injure the tree by undue pressure if it remained so attached for several seasons. For Roses it seems especially suited. This label is the invention of Mr. W. F. Bateman, of Low Moor, Bradford, who is perfecting a machine for stamping them in quantity. In my third class I can mention only the wooden labels in common use among nurserymen and gardeners; and these answer their purpose so well for some departments that I have endeavoured to ascertain at what cost they can be made; for when they are wanted by thousands this is a consideration. I give the result of my experiment. A bundle of laths, called "doubles," can be got for 3s., and ought to contain from 300 to 360 feet run of lath. The bundles vary in length, but those I had by me happened to be just 3 feet long. One of them was cut into eight lengths, each of which was split into six pieces, first by dividing each piece into three in the direction of its

width, and then laying each of the three on the bench and applying the chisel longitudinally in the middle of it. In this way an average of from forty to fifty labels were got from one lath, allowing for occasional failures on the one hand, and additional splittings on the other in those portions where the lath happened to be unusually thick. They were smoothed and pointed with a sharp chisel, and fifty were produced in less than three-quarters of an-hour, and at a cost of less than a half-penny. They averaged about $4\frac{1}{2}$ inches long and about three-eighths of an-inch in width—wide enough for a single name. A few can always be left of double width for more than one line of writing. They can be rapidly painted held three at a time, and white lead, thinned with equal parts of linseed oil and turpentine, applied with a brush on the part where the name is to be written. This can be done either with a common pencil, or with one of Wolff's indelibles, if preferred. Many of these labels will probably be decayed or lost before another year comes round; but the strongest will be likely to turn up again, and they will serve their purpose a second season. When writing on zinc with the fluid recommended, care should be taken that the surface of the metal is clean. To ensure permanency, the label should be well rubbed with emery-paper before the name is written on it. Any of the varieties of label lately recommended in THE GARDEN, I have no doubt, would be found to answer by those who are willing to carry out the instructions given in each case; but I have always found the others sufficient for all purposes. B. S.

THE ROCK-GARDEN IN MAY.

HAVING had the pleasure of inspecting Mr. M'Nab's rock-garden in April, I can easily imagine how beautiful it must be now. Anyone who visited it last month must have been impressed by the beauty of masses of *Scilla bifolia*, and of the richness of *Primula purpurea* and *Iris reticulata*. *Draba aizoides* is also a bright little plant, of a purer yellow than *Gagea lutea*, which flowers at the same time. For some years I have noted the dates on which the first blooms of spring-flowering plants have opened, and I shall be happy to send my notes to you when Mr. M'Nab publishes his. It will be interesting to compare the dates of the east and west coasts, and one can imagine such a record being interesting if the world goes on another 200 or 300 years, as showing the modification of climate. Here is Evelyn's list of "Flowers in Prime, or yet Lasting" in the month of May, as he gives it in his "Kalendarium Hortense:—"Late-set Anemonies and *Ranunculus omn. gen.*, *Anapodophylon*, *Blattaria*, *Chamæiris*, *Angusti-fol*, *Cyanus*, *Cytisus*, *Maranthe*, *Cyclamen* (of what sort could this be?), *Heleborine*, *Columbines*, *Caltha palustris*, double *Cotyledon*, *Digitalis*, *Fraxinella*, *Gladiolus*, *Geraniums*, *Horminum creticum*, yellow *Hemerocallis*, striped *Jacinth*, early bulbous *Iris*, *Asphodel*, yellow *Lilies*, *Lychnis*, *Jacea*, *Bellis* (double white and red), *Millefolium luteum*, *Phalangium*, *Orchis*, *Lilium convallium*, *Span. Pinks*, *Deptford Pinks*, *Rosa* (common, *Cinnamon*, *Guelder*, and *centifol.*, &c.), *Oleaster*, *Cherry-bay*, *Trachelium*, *Cowslips*, *Hesperis*, *Antirrhinum*, *Seringas*, *Sedums*, *Tulips serotin*, &c., *Valerian*, *Veronica* (double and single), *Musk Violets*, *Ladies' Slipper*, *Belvidere*, *Stock-gilly-flower*, *Spanish Nut*, *Star-flower*, *Chalcedons*, ordinary *Crowfoot*, red *Martagon*, *Bee-flowers*, *Campanulas* (white and blue), *Persian Lilies*, *Honey-suckle*, *Bugloss*, *Homer's Moly* and the white of *Dioscorides*, *Pansies*, *Prunella*, purple *Thalictrum*, *Sisymbrium* (double and simple), *Leucojum bulbosum serotinum*, *Peonies*, *Sambucus*, *Rosemary*, *Stæchas*, *Sea Narcissus*, *Barba Jovis*, *Laurus*, *Satyrion*, *Oxyacanthus*, *Tamariscus*, *Apple Blossoms*, &c." The date of this list is 1678. We have largely added to our store of exotic hardy plants during the last 200 years; yet I think comparatively few modern gardens can show a tithe of the plants named above, all of which probably the author grew in his own garden at Wootton. In 200 years hence will there be, do you think, as much fragrance lingering round a list of Mrs. Pollock and Lady Cullum *Geraniums*, *Golden Feather Pyrethrum*, and *Ageratum*, as hangs about this quaint catalogue of old-world flowers?

SALMONICEPS.

NOTES OF THE WEEK.

— MESSRS. BACKHOUSE, of York, have sent us some specimens of the bright and pretty rock-plant, *Cytisus Arduini*, a native of the south of France. It is a hardy and very graceful plant for the rougher parts of the rock-garden, and for beds or borders of choice dwarf shrubs.

— MESSRS. STEWART & SONS, of Dundee, inform us that their exertions to reduce the cost of transit on nursery goods have been successful, and that the several railway companies have agreed to reduce the present rates, after the 1st of June, to what they were last year.

— WE have received from Mr. Hill, Keele Hall, Staffordshire, a bunch of Black Alicante Grapes, preserved on the French plan in bottles of water since the first week of January last. As regards appearance, it was all that could be desired, the berries being plump, sound, and beautifully covered with bloom. The flavour, too, was excellent—little inferior, if any, to that of freshly-cut Grapes.

— AT the last exhibition of the Royal Horticultural Society Mr. R. Dean exhibited a large potful of the Irish Butterwort, in the freshest possible condition. Its delicate apple-green leaves are exceedingly curious, as they have the power of entrapping small flies and other insects. The flowers of this plant are of a rich violet-purple, and the specimen to which we refer was one of the most interesting in the exhibition in question. It is not unfrequently met with in the south of Ireland, especially near Killarney.

— SOME more special prizes are announced by the promoters of the International Potato Exhibition, to take place at the Alexandra Palace on September 29 and 30. Messrs. Bliss, of New York, offer special prizes for three distinct varieties of New American Potatoes that have been offered in commerce for the first time in the years 1874-75, nine tubers of each; and Mr. John Coutts, Covent Garden, also offers special prizes, for three distinct varieties of English Seedling Potatoes not yet in commerce, nine tubers of each. The sum of five guineas is given in each case.

— IN addition to a very large catalogue of American varieties, Grape growers will find much interesting and suggestive matter in the bulky pamphlet of Messrs. Bush, Son, & Messner, of Bushberg, Mo., which we have received this week, who are Vine growers on a very extensive scale. Many of the kinds are figured, and the letterpress occupies eighty double-column octavo pages. Messrs. Ellwanger & Barry, of Rochester, N. Y., send us their unique and very complete "Descriptive Catalogue of Hardy Ornamental Trees, Shrubs, Roses, &c." It is abundantly illustrated, but the cuts do not show the beauty of the fine specimens in their nurseries.

— AT this season of the year all who do not wish the delicate points of good Asparagus to be destroyed in the boiling, should bear in mind that they are never immersed in water by those who understand cooking Asparagus. The heads are all cut as nearly as can be to one length, tied in a compact bundle, and placed erect in the water, leaving about an inch of the tops out of it. In this way the tips of the shoots of even the largest Asparagus are perfectly cooked, and the lower parts are made more tender than they otherwise would be. This is the only way in which the fine examples of blanched Asparagus now in our markets can be satisfactorily prepared.

— WE hear that a building is likely to be erected at Kew to receive the national botanical library and the collections of dried plants, at present deposited in a house which is small and otherwise inconvenient for the purpose. The value of the collections at Kew to working botanists cannot be over-rated, and the manner in which they are arranged is praiseworthy. There is some difference of opinion as to the desirability of amalgamating the collections at Kew and the British Museum. Our own opinion is that London, and London only, is the proper place for the national herbarium; while Kew should possess one in all respects sufficient to assist in the nomenclature of its living collection and for all the other work of a national garden.

— WE have lately received a flowering specimen of the rare and singular *Cypripedium japonicum* from the Colchester Bulb Company, who have flowered it this spring for the first time in Europe. It is a native of Japan, and is well figured by Blume, and also more recently by M. Van Houtte in his "Flore des Serres." The plant is about a foot in height, and its hairy stems, which are as thick as one's little finger, bear two plicate fan-shaped leaves of a bright green colour, rather jagged or erosely cut around the margins. The flowers are solitary on hairy scapes, the sepals being of an apple-green tint; the petals, too, are of the same colour, but are dotted with purplish-crimson at the base; the lip is large, and curiously folded in front, as in the better-known *C. (humile) acaule*, to which it seems most nearly

allied; the colour of the lip is a soft, creamy-yellow, with bold purple dots and lines.

— It is stated by the "Garten Zeitung" that the number of new varieties of Dahlias offered by German growers this year is 530, of which number one grower, Sieckmann, furnishes 405.

— It is proposed at the congress of botanists which is to be held next year at Brussels, to consider a plan for compiling a Hortus Europæus, or systematic catalogue of garden plants.

— It has been arranged to hold an international fruit and flower show at the Alexandra Palace on the 2nd, 3rd, and 4th of September next. A liberal schedule of prizes will be issued in a few days.

— A CORRESPONDENT informs us that a small bed of Lily of the Valley is in flower in a very small court off Fetter Lane, Fleet Street. There is a very healthy bed of the same plant in front of a house in the Harrow Road. It has been in the same position for many years, blooming admirably beside the dusty street.

— PLANTS of *Rhododendron* 18 to 20 feet high at Keele Hall are now covered with thousands of trusses of bloom of various shades, from purple to almost scarlet. This season being a late one they have escaped spring frosts, and are finer than they have been during the last quarter of a century. Sixteen years ago they were in bloom on the 13th of April, when snow laid 6 inches deep on the ground, and the sight of the crimson trusses peeping through the snow was one not readily forgotten.

— It may interest some of our readers to know that the new Judge who has been appointed to succeed Mr. Justice Huddleston in the Court of Common Pleas is the son of the late Dr. Lindley, editor of the "Gardener's Chronicle," and so long connected with the Royal Horticultural Society. Mr. Nathaniel Lindley, Q.C., although comparatively young, was one of the best known and soundest lawyers in Vice-Chancellor Hall's Court, of which he was one of the leaders. He is also the author of an able "Treatise on the Law of Partnership."

— AT one of the recent meetings of the Central Horticultural Society of France Dr. Baillon read an interesting note upon a new kind of *Gymnocladus*, which he had named *chinensis* after its birth-place. This tree, which will probably be hardy at least in some parts of France, has two advantages—it will enrich our collection of forest trees, and promises also to be a source of material wealth from the value of its pods, which are likely to be largely used in the manufacture of soap and similar substances. This interesting discovery was made by M. Payen, who states that this material is used in China instead of soap.

— It is reported that an Italian professor has discovered that perfumes from flowers have a chemical effect on the atmosphere, converting its oxygen into ozone, and thus increasing its health-imparting power. As the result of his researches, he states that the essences of Cherry, Laurel, Lavender, Mint, Juniper, Melons, Fennel, and Bergamot are among those which develop the largest quantities of ozone, while Anise and Thyme develop it in a less degree. Flowers destitute of perfume have no such effect. He recommends that dwellers in marshy or otherwise unhealthy localities should surround their homes with a profusion of the most odoriferous flowers.

— ON Saturday last another large portion of ground on the northern side of the embankment—laid out as a garden—was dedicated to public use by the Metropolitan Board of Works. It extends from the Outram Monument, near the Charing Cross Railway Bridge, westward, as far as the boundary line of the private grounds of Whitehall Place, fronting the Thames—in other words, far towards Westminster Bridge; thus making three public gardens between the Temple and the Victoria Tower. The expense of fencing and laying out the latest addition to these ornamental grounds is understood to have been about £3,000, and the total cost, including the purchase money, between £6,000 and £7,000. The garden is from the plans of the architect of the Metropolitan Board, and the works were carried out by Mr. Meston.

— EXPERIMENTS have been made in Algeria by M. Rivière with the object of making Pears, grafted upon seedlings, fruit sooner than they otherwise would do. The stock upon which it is usual to graft Pears is, as is well known, either Quince or seedling Pears; but the Quince only flourishes in rich, deep soil, and it is comparatively short-lived. On the other hand, the Pear grafted upon a seedling has the advantage of adapting itself to any kind of soil, but it is long before it comes into flower, and its first fruits are bad. M. Rivière set himself the task of uniting the qualities of both kinds of stock, and to accomplish this has cleft-grafted upon seedlings the Quince, and subsequently upon that the variety from which he wished to obtain fruit. He intends making known the result of this operation, which does not appear to have been previously tried.

THE HOUSEHOLD.

CARROT COOKERY.

It may not be unacceptable to your readers to supplement Mr. Guichenon's article on the Carrot, which appeared the other day in *THE GARDEN* (see p. 358), by a few tried receipts for cooking that excellent vegetable. I will begin with Carrot soup, first premising that the French Scarlet variety is the one I prefer for most cooking purposes, although several other kinds mentioned in the article just alluded to are good when carefully prepared.

Carrot Soup.—Take 1½ lb. of Carrots which have been first brushed very clean; then boiled, until tender, in slightly-salted water; mash them to a smooth paste, or rub them through a sieve; mix the paste with 2 quarts of boiling soup (strong beef broth will do); season this with pepper and salt, and add, before being finally boiled up, a small lump of sugar and a piece of butter. Serve with a dish of bread cut into small dice and fried in butter.

Boiling Carrots.—Brush them very clean (a process not always performed with sufficient nicety), or pare them if at all old; divide them, and cut the thick part into quarters, should they be very large; throw them into well-salted boiling water. Old Carrots require from an hour and a half to two hours; young ones are tender in from twenty to thirty minutes. A tureen of melted butter should be served with them. Carrots form a good accompaniment to boiled beef, and it is usual to boil them in the water with the meat; the colour is, however, better if they are prepared separately.

Carottes au Beurre.—Boil sufficient Carrots for a dish until they are quite tender; drain them well, and whilst this is being done just dissolve from 2 to 3 ounces of butter in a saucepan, and strew in some minced Parsley, some salt, and white pepper or cayenne; then add the Carrots, and toss them very gently until they are covered with the sauce, which should not be allowed to boil. Cold Carrots may be re-warmed in this way.

Carrots (Entree).—Select some good Carrots of equal size, and cut the upper parts into even lengths of 2½ inches, then trim the end of each into a point so as to give the Carrot the form of a sugar loaf. When all are ready throw them into plenty of ready-salted boiling water, and boil them three-quarters of an hour; lift them out, drain them well, arrange them upright and all on a level in a broad stew-pan, and pour in good hot beef broth or veal broth to half their height; add as much salt as is needed and a small teaspoonful of sugar, and boil them briskly for half-an-hour, or longer should they require it. Place them again upright in dishing them, and keep them hot while a little good brown gravy is thickened to pour over them. This may be mixed with a little Onion minced and a teaspoonful of minced Parsley, or they may be sauced with béchamel or white sauce.

Mashed Carrots.—Boil and mash some fine red Carrots, and dry them in a saucepan over a gentle fire; mix them with 2 ounces of butter, cut into small bits, keeping them well-stirred. Add salt and cayenne, and serve them garnished with croutons of fried bread.

Stewed Carrots.—Half-boil half-a-dozen large Carrots without cutting them; then slice them into a stew-pan; put in enough good stock to nearly cover them, with pepper and salt to taste. Stew them till tender; then mix in a separate vessel half-a-pint of cream and a table-spoonful of flour, and add to the Carrots with 1 ounce of butter. Boil up and serve. Small young Carrots may be dressed in the same manner, and will, of course, require less time to cook them.

Carottes a la Maitre d'Hotel (a genuine French receipt).—Scrape twenty small young Carrots and wipe them, but do not wash them. Put them into a pan with 6 ounces of fresh butter; cover the pan, and toss the Carrots over the fire from time to time. After a quarter of an hour add salt and pepper, some chopped Chives, and Parsley. Cover the pan and gently toss it again from time to time, until the Carrots are tender. If you use large Carrots, cut them into slices and boil them in water until they are nearly done. Drain them and finish them as above.

Carottes a la poulette.—Take some young Carrots; scrape and wipe them carefully. Put them in a pan over a moderate fire, with 6 ozs. of butter and a tablespoonful of flour; toss them repeatedly,

and take care the flour does not become brown. Pour a tumblerful of milk into the pan, cover it, and let the Carrots simmer slowly until they are done. Then take the pan from the fire, and pour into it two yolks of eggs, mixed with a tablespoonful of good cream, and a little pepper and salt; warm these ingredients, taking care not to let them boil, and serve.

Carottes au jambon.—Put into a pan 6 ozs. of butter and a tablespoonful of flour; simmer these over a quick fire, until they become slightly brown. Add a gill of boiling water, then 6 ozs. of raw ham cut into small dice, a little salt and pepper, a Bay leaf, a small bunch of Thyme and Parsley, a large Onion, and six large Carrots cut into slices the size of a half-crown. Cover the pan, and let the Carrots boil until they are done. Then take out the seasoning, and serve. N. B.—This receipt answers well for Turnips.

Carottes a la Menagere.—Put into a pan 6 oz. of butter and a tablespoonful of flour; stir the flour until it browns slightly, then add half a tumbler of white Burgundy and a gill of broth; add the Carrots, previously blanched and sliced, and cover the pan. Let the same boil quickly until they are sufficiently done; then remove the pan from the fire, and pour into it two yolks of eggs mixed with a few drops of water. Just stir these over the fire without letting them boil, and serve.

N.

BARBE DE CAPUCIN.

THIS, which is Chicory blanché, is a common salad plant in Paris, and, every spring, examples of it, imported from the Continent, may be seen in Covent Garden Market. Its taste, however, is too bitter for most people, and, on that account, the Witloof, which we figured in our last issue (see p. 391), may be expected to supersede it. It is easily blanched, either in the open ground, or in a cellar, and is sold in bunches like that represented by the accompanying illustration.

Bunch of Barbe de Capucin.

BEETLES IN TEA.

I HAVE received communications from three firms, and a sample from one, complaining of the occurrence of beetles in tea, and inquiring what their name is, whether they are of Chinese origin, and what they eat. A few of the details may be given here without mentioning any name except that of the beetle. The single sample

I have examined contained about fifty beetles in the perfect state, and several larvæ of beetles. The former are about the size of grains of wheat, and of a chestnut-brown colour. Some of them were completely clothed with short pale down, the rest perfectly smooth and shining, evidently the result of the down having been rubbed off by continual journeys among the dry and unyielding tea leaves. The larvæ or grubs were nearly white, and there were two chrysalids, also white. The parcel from which the sample was drawn consisted of about a hundred chests, all of them more or less infested with the beetle. The chests had been in a bonded warehouse in London three or four years. It is a very inferior parcel of tea—indeed, one which no respectable dealer would be likely to buy—and, now that it proves to be infested with beetles, it will probably be destroyed. My first object was to ascertain the name of the beetle, my second its country, and my third its food. I will say something on each of these points.

1. The Name.—Directly I saw these beetles I recognised a household pest, called by entomologists *Niptus hololeucus*. In the year 1838 I found similar beetles in an old cupboard at Deptford, in company with sundry and divers boots and shoes that had been laid aside as leaky and useless, and ought to have been thrown away. The beetle was quite new to me, and, being desirous of obtaining a name for it, I took it to Mr. Stephens, then the highest authority on beetle nomenclature, and, to my delight and astonishment, it was pronounced perfectly new. I, therefore, suggested that it should be called *Ptinus holosericeus*; but this name subsequently gave way to an earlier name proposed by Faldermann, and in 1839 it appeared in the appendix to Stephens's "Manual" as *Ptinus hololeucus* of Faldermann; and this name has again yielded to a third, *Niptus hololeucus*, by which the insect is now generally known, although some entomologists have expressed a doubt whether Faldermann's

beetle and the tea beetle are exactly the same, and should it be shown they are distinct, the tea beetle will, of necessity, receive another name.

2. The Country.—As the beetle is now naturalised everywhere, it is scarcely probable that its aboriginal country will ever be made known. It is said to have been introduced into England from Persia *via* Turkey; but, on investigating this report, I can find no confirmation—it seems to have been entirely conjectural. Of course, the fact of its abundant occurrence in tea suggested the idea of its importation from China; but this seems equally unsupported by evidence. Moreover, as the creature was a London pest in 1839, and has remained so ever since, and as it was not noticed in tea until 1874, there seems no good ground for supposing it imported with tea; and there is no evidence to show whether it exists in China, so as to get into tea at its first source. On the other hand, seeing that it is so abundant in Britain, especially, but not exclusively, in London, and that it had enjoyed abundant opportunities for establishing itself in tea that has been bonded in London for three or four years, it seems scarcely reasonable to conclude that it first reached us from China. To prove the negative would be difficult, perhaps impossible; but to establish such a theory it is absolutely necessary that it should have been known as an inhabitant of China before it was observed in London.

3. The Food.—It appears to be omnivorous; it eats tea, linen, wood, oatmeal, bran—indeed, every vegetable substance utilised and warehoused by man for food or clothing; it is also charged with perforating boots and shoes when not in use; leather seems the only animal substance it is known to devour. It is to be found in nearly every printing-office or paper-warehouse, but I have no evidence that it eats or damages papers; and, as to metal type, the compositor might regard it with indifference, and, if he saw it nibbling at a quad or a thin space, exclaim with Junius and with Æsop, “Cease, viper, thou bitest against a file!” It may be observed that several other beetles are equally omnivorous, and therefore cosmopolitan; they accompany man in all his wanderings and migrations, avail themselves of all his means of transport, eat every kind of food that he eats, clothe themselves with the material he selects for vestments, and for repose avail themselves of his dormitory, whether in the hovel or the palace; such, for instance, are *Dermestes lardarius* and *Dermestes murinus*. In conclusion (says Professor Newman, in the “Field”), I may say that I can suggest no remedy; all insecticides must be useless, unless you can persuade the Niptus to adopt them as food in lieu of the various esculents which I have already enumerated as included in his ascertained bill of fare.

WINE WITHOUT GRAPES!

At the session of the International Viticultural Congress, in October, 1874, at Montpellier, France, M. Saint Pierre, professor in the medical school of that city, by invitation, gave some facts in regard to the fabrication of imitated wines, a branch of business which had of late rapidly developed in Hérault, especially at Cette and Mèze. The product of this manufacture is mostly exported, the bulk being sent to Russia, Denmark, Holland, England, and North and South America. Cette alone makes nearly 8,000,000 gallons per annum, worth about 15,000,000 francs. Two-thirds of this aggregate are consumed in America. The only wines that can be successfully imitated are those rich in alcohol, such as the wines of Spain and Portugal. It is not true that Grape juice is the only thing omitted in the composition of these wines, as that is the cheapest ingredient. Nor is colouring matter used to any extent, as the wines to be imitated are white. The Portuguese formerly coloured their wines with Elderwood, but abandoned it on finding that it injured the wine. The imitation of Spanish wines utilises a large amount of cheap wines in the south of France, the production of which has been stimulated of late years. These wines show scarcely 11° of alcohol, but with the addition of syrup of Mulberry and alcohol the strength is raised to 21°. The professor, with great frankness, pleads for the encouragement of this industry. The members of the Congress visited Cette and Mèze, and inspected several manufactories. One of the largest at Cette had then stored over 280,000 gallons in cellars containing from 80,000 to 100,000 gallons each. The total value of the whole deposit is stated at £40,000. The cost of storage, including casks, &c., amounted to £26,000, about 8s. for every twenty-two gallons. At Mèze one establishment astonished the visitors by the vast extent of its cooper-shops, and its steam-engines of great power pumping the wine from great cisterns into the casks.

FLOWERS and fruits are always fit presents: flowers, because they are a proud assertion that a ray of beauty outvalues all the utilities of the world; fruits, because they are the flower of commodities, and admit of fantastic values being attached them.—EMERSON.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

CABBAGES, Cauliflower and Broccoli are all liable, in some gardens, to suffer seriously from the ravages of the root-grub. In old gardens the plants are generally the most affected; and to such an extent, in some places, does this occur, that the summer crops of these vegetables are almost destroyed. Besides the whole or partial loss of the crop, this is very annoying to those who take a pride in seeing in their kitchen gardens that unbroken uniformity in the different vegetables grown that gives evidence of good management; yet, in soils the most infested with these pests, a little extra labour at the time of planting will secure these vegetables, in a great measure, from destruction. At this season amateurs will do well to provide a bushel or two of dry powdered lime, to which an equal quantity of soot should be added; stir the two well together, and keep the mixture anywhere where it will be dry; this quantity will suffice for a good-sized garden. When the different crops for summer and winter use are being put out, use the planting-trowel instead of the dibber, make the holes large enough, and, as the plants are dropped into them, half-fill them up with earth; then, if the weather and state of the soil are such as to require it, give them a good soaking with water, after which put to each plant, all round the stem, a half-handful of the lime and soot, then draw in the remainder of the soil. This simple process will take a little more time than planting without the use of the mixture; but those who use it will be spared the annoyance, through the hot dry months of July and August, of seeing their plants turn that peculiar blue tint in the leaves, and flag in the sun, which is a sure sign that the roots are gone, and that all affected in this way may be consigned to the refuse heap. Where water is given at the time of planting, it is necessary to apply it as above directed, before the lime and soot, as, if the latter is put to the plants first, it will be washed away from the stems, and only have a partial chance of being effectual. The rains we have had lately will now make everything grow apace, and amateurs will find this a busy time; yet the attention devoted to the flower garden should by no means be allowed to interfere with the equally important kitchen garden. The rapid growth that most vegetable crops are making necessitates continual watchfulness. Early Turnips will now require thinning, as also Carrots, as soon as these are strong enough in the tops to draw. It may be taken as a rule that any crop which requires thinning is benefited by this being done as soon as the plants are large enough to handle. We frequently see this deferred until they are so large that their necessary removal always seriously disturbs the roots of such as are to remain. In thinning early crops, especially of such things as Turnips and Carrots, too many should not be removed; for, as soon as they are large enough for use, a portion all over the beds may be gathered, which will give more room to those left to increase in size. Early Carrots 4 inches apart at the first thinning will have space enough. Do not allow Peas to get too large before they are stuck, as, if broken down by the wind, they never take kindly to the supports. As soon as the surface gets sufficiently dry, ply the hoe on all vacant spaces; not only is this disturbance of the soil desirable for the destruction of weeds, but it is also a means of helping the ground to retain its moisture—a matter of great importance in dry situations.

Tripoli Onions Sown in Autumn.—Where large mild Onions are required for cooking, these can only be got by giving them sufficient room. They should at once be thinned out 8 or 9 inches apart, and, if the soil was not sufficiently rich at the time of sowing, the produce will be much larger if it now receives a sprinkling of guano and soot, mixed in equal proportions. Delicate flavoured Onions are much esteemed for culinary purposes; but, unless they are grown freely in soil well enriched, they cannot be had.

Thinning Spinach.—Thin out the early crops of Spinach sown between rows of Peas and in other situations. A not uncommon practice is to leave three times the number of plants of this vegetable that there ought to be, struggling for existence, the result of which is that there is not a single leaf more than half-developed, the whole being correspondingly tough and stringy, running to seed much sooner than it would if allowed sufficient room. In thinning, leave the plants 6 inches apart.

Flower Garden.—Now bed out Pelargoniums, Verbenas, Lobelias, Ageratums, and Petunias, provided these have been sufficiently hardened; but, any plants that have been late struck and not had enough time to prepare them for exposure to the open air, had better have another week's gradual preparation, rather than submitting them to be checked by too sudden a change. In putting out these summer bedding plants, account should be taken of the time when the greatest display will be required. When it is desirable to have the whole a complete sheet of bloom as early in the season as possible, it is necessary to put the plants in the beds much closer than

when the greatest effect is wanted later in the season. In the neighbourhood of London, in most large gardens, if the flower garden is not at its best before the close of the London season its value is, comparatively speaking, lost. In places where the principal display is not wanted before August, the plants should be put in further apart, or they become somewhat exhausted before they are required to be at their best. Amateurs, whose enjoyment of their floral display will, in most cases, be commensurate with the length of time it lasts, will do well to take a medium course in planting. The distance between the plants will in, some measure, be determined by their size and strength when planted, and the nature of the soil. In this style of gardening it is a desideratum to have as good a sheet of bloom on the beds for as long a period as possible, but where the plants are so crowded together they cannot hold out, the foliage of many becoming bad. Individual tastes vary in the arrangement of a flower garden as in other matters, yet there is no reason why anyone should confine his practice to the conventional ribbons, lines, circles, or segments of circles, which it would appear almost impossible to eliminate from modern flower gardening. There were irregular combinations of different colours and plants many years ago that have never been surpassed in pleasing effect. Take, for instance, the beds of Mangle's Variegated Geranium and Purple King Verbena, planted together so as to run into each other as irregularly as possible. This, and many similar mixtures did much to remove the objectionable formality, with reason complained of by many at the present day. It is not alone by a judicious blending of colours in an informal way that summer flower gardening might be stripped of its greatest defects as seen from an artistic point of view, but much might be done in the form and height of the plants associated together. To do this, it is not necessary to plant large coarse-leaved subjects in the midst of low-growing flowering plants. From the wealth of different forms we possess, there are numbers of light plants of elegant habit that would relieve the too even surface of colours in mass, without hiding or unduly shutting out from view all that it is desirable to be seen from any point. The old *Humea elegans*, now put in the shade by plants not possessing half its merit, is one that well illustrates the habit and style of the subjects required for relieving the even surface of form and colour. *Acacia lophantha* is well adapted for the purpose, as also *Cordyline australis*, *Acer Negundo variegatum*, in specimens varying in height from 2 to 4 feet, according to the situation for which they were required.

Herbaceous Plants.—There is nothing like getting the seed of such herbaceous plants as are generally raised in this way sown in good time, by which means they get strong before winter, instead of struggling for existence through the dry late summer months, requiring much more nursing than if they had attained more strength early in the season. Polyanthus, Delphiniums, Sweet Williams, Aquilegias, with a host of similar kinds, if sown at once, will make plants by the autumn, superior in quality to what they would be if the sowing is longer deferred. Sow on a well-prepared piece of ground, with the surface made quite smooth, and cover the seeds lightly with finely sifted vegetable mould; if the situation is a little shaded from the mid-day sun, so much the better; but it should not be where the plants will be weakened and drawn up by the too near proximity of trees.

Watering.—Although the soil is now in moist condition; yet, should we have an absence of rain for even a short time, the ground quickly becomes dry, and surface-rooting plants soon suffer unless water is given them. It is necessary to impress upon amateurs that it never should be given until absolutely required, and, when applied, it should always be in quantities sufficient to moisten the soil as far down as the roots penetrate; when this is not done, it merely excites the surface roots, leaving those that are deeper, and generally of more importance to the full development of the plants, in a comparatively inactive state; and, unless these surface-roots, excited by this sprinkling system of watering, are kept supplied, they perish as quickly as they were formed, in which case the plants so treated suffer more than if no water had been given. This applies with equal force to both flowering plants and vegetables. To all to which water is given, give it thoroughly, even if some things be left without altogether; this will be found better than sprinkling or half-supplying the whole.

Pits and Frames (Cucumbers).—See that these do not become too crowded, by going over them once a fortnight and removing superabundant shoots. Keep the heat sufficiently up by adding fresh hot linings as required. Seeds of Primulas should now be sown, if good plants are to be looked for at the proper season; drain the pots and fill them to within an inch of the top with sifted loam, to which has been added one-fourth of fine leaf soil and some sand; on this sprinkle a little sand, give a moderate watering so as to settle the soil, smooth the surface by gently pressing it with the bottom of an

empty pot, then sow the seeds, over which sprinkle as much sand as will just cover them, and place them in a gentle heat where the surface will not be exposed to the drying influence of the sun, the object being to get the seeds up before much water is required; yet the soil must not be allowed to get too dry. Loose pieces of glass placed over the tops of the pots help to keep it moist. Cinerarias should also now be sown, preparing the soil, sowing the seed, and afterwards treating them as advised for the Primulas.

Flower Garden and Pleasure Ground.

After the middle of this month, it is generally considered safe to commence bedding-out in the flower-garden; and this may, during most seasons, be done without danger, as regards established plants of such kinds as the Verbena, zonal Pelargonium, &c.; while, at the same time, the planting out of the more tender species, such as the Colens, Iresine, Alternanthera, &c., had better be deferred until the last week of the present month, or, if the weather is not then very favourable, it may with advantage be deferred until the beginning of June. Wherever a system of spring-bedding has been adopted, the spring-flowering plants must now be removed to the reserve garden, and the change will this season cause something of a feeling of regret, as the beauty of many early-flowering favourites has not as yet passed away. This is more or less the case during almost every season, but especially in those which, like the present, have been unusually backward. But as regards the parterre, or flower-garden, there must be no compromise, as the time which the seasons allow for the display of summer bedding plants in the open air is too short to admit of any curtailment, and the spring subjects must be at once removed. This removal, however, should be effected with the greatest possible care. In lifting early Tulips, and other bulbs, from the flower beds in an unripened condition, as much soil as possible must be allowed to adhere to them, and they should at once be planted in a somewhat shady situation. After being well-watered, they should be allowed to remain until the bulbs are thoroughly ripened, when they should be cleaned and stored away. As soon as the flower-beds and borders are at liberty, the margins, if of Grass, should be neatly cut with the edging-iron, and the compost, which should have been prepared for them, should now be spread upon the surface of the beds, and well incorporated with the soil, which should be stirred up to a depth of not less than 2 or 3 feet. The compost should also be of a somewhat concentrated and enriching character; for, where the soil is compelled, as it were, to do double duty, liberal treatment must not be withheld. For such plants as the Calceolaria and Verbena there is very little danger of making the soil too rich; and even the tricolor and variegated Pelargoniums, and various other plants grown for the beauty of their foliage, are generally found to be most effective when furnished with a moderately rich and friable soil. But, with regard to the ordinary green-leaved and zonal Pelargoniums, a very rich or highly-manured soil is undesirable, and tends more to the production of foliage than of bloom. It is, of course, supposed that the arrangement of the flower garden, or the manner of planting its beds, borders, vases, &c., was decided last autumn, and that the necessary material has been prepared during the intervening months. In making the necessary arrangements care should have been taken to avoid as much as possible the production of a glaring or too gaudy effect, but rather to aim at a harmonious combination of the various shades, regard at the same time being had to the height and habit of growth of the various plants employed for the purpose, as, however necessary it may be to carefully arrange the various shades of colour, form, at the same time, must not be lost sight of. What are known as sub-tropical plants are generally somewhat tender, and their planting may with advantage be deferred for a short time; and, if possible, the site selected for them should be somewhat sheltered, as they consist principally of species with large and ornamental leaves, which are very apt to be disfigured if exposed too early to cold and boisterous winds. Such plants should be of considerable size when planted, and should have been gradually inured to exposure in the open air. They should be planted in beds of rich or highly-manured soil, and should be abundantly supplied with water during dry weather, in order to induce a rapid and luxuriant development of the magnificent foliage which constitutes their chief beauty, and which, in suitable situations, amid appropriate scenery, seldom fails to produce an effect which is remarkably pleasing. The soil of beds which are to be planted in the "carpet" style should now, after being enriched as may be considered necessary, be also rendered perfectly smooth and level, and the pattern of the bed should be very carefully sketched upon the surface of the same with a pointed stick, or some similar instrument. Well-rooted cuttings and pricked-out seedlings will be found to be better suited to this style of planting than larger plants turned out of single pots. Plants shaken out of store-pots should be pricked out into the beds some-

what thickly, in order to produce immediate effect, spaces being left for such tender species as the *Alternantheras*. In this style of planting it is quite necessary to observe the greatest exactitude and neatness, as, without this, every attempt will be sure to prove a failure. The plants should be well watered with a fine rosed watering-pot as the work proceeds, and for this purpose Le Butt's patent watering-pot will be found to be exceedingly serviceable. Shrubberies are now gay with flowering shrubs of various kinds, including the early-flowering *Rhododendrons*, *Azaleas*, *Kalmias*, &c., and these during dry weather should be well supplied with water at their roots, otherwise their flowers will not last long. Many of the hardy herbaceous plants which usually occupy the margins of clumps and belts of shrubs and ornamental trees, will now be in bloom, and may require to have their shoots and flowering-stems regulated and tied up. These matters should not be neglected during the busy season of planting out, as such flowering plants tend very considerably to supply any want of bloom which may exist during the interim between the two periods of spring and summer bedding. About this time all kinds of Pine and Larch seed should be sown; before consigning the latter to the ground the seed should be put in "steep" as it is commonly termed, that is, spread on the floor to the depth of 10 or 12 inches, and completely saturated with water; the seed should be turned regularly twice or thrice a day for a week or so, by the end of which time the grains will have swelled gradually and the "eye" have become more prominent; many failures in Larch seeds germinating occur when this operation is not carefully attended to. All herbage in young plantations must be cleared off, and all seed-beds weeded; young weeds coming up must be watched and caught in the act, and the pruning of all evergreens finished.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

Pot Roses that have been forced during the spring and winter months will require a little attention at this season, so as to prepare them for another winter. The whole of the pot Roses whose flowering this season is finished should be carefully re-potted in fresh loam and rotten dung, mixed with plenty of sharp sand. In potting Roses at this season of the year, as much as possible of the old or sour soil should be very carefully removed from the roots by a sharp-pointed stick, without breaking them. The pots must be all well washed inside, as the same sized pots do for many years for pot Roses. The two sizes I recommend are Nos. 12 and 8. In some cases larger pots are required for strong-growing Roses, such as *Maréchal Niel* and the *Hybrid Chinas*. The drainage must be thoroughly attended to. To drain a pot well, the bottom crock should fit as evenly as possible, so as not to allow any space for worms to get in. Afterwards, about 1 inch of small crock shreds or charcoal must be placed over the bottom of the pot, so as to form an even surface, and then some turf fibre or rough pieces of turf should be laid on the top, so as to keep the fine soil from being washed down between the crocks. In watering, much depends on the drainage of pot Roses to ensure success, for pot Roses become sickly, and finally die, owing to stagnation occasioned by bad drainage. In potting the Rose, if a plant worked on the Briar stock, it does not matter how deeply it is planted, as the Briar grows under any ordinary treatment; but if Roses are on their own roots, care should be taken not to pot them too deeply; for the soil, if raised up too high, often causes a Rose to shank off close to the top of the pot. I have also noticed other stocks go the same way. The plants should all be removed to a shady place for a few weeks, till they have made fresh roots. Hybrid Perpetuals may be placed out of doors altogether. Tea Roses require a cold pit. Turf pits are best for them, and a little leaf mould may be mixed in the soil for them, as they require much lighter soil than Hybrid Perpetuals, if they are on their own roots. Take off all flower-buds, and cut out all strong rampant shoots, which rob the plant of its strength to flower another season. If they are allowed to grow, the plant will not break well for forcing; the small shoots are much weakened by their growth, and the plant becomes completely spoilt in shape.—H. G.

Indoor Fruit Department.

Vines.—Planting out young Vines in a growing state is a system which may be practised with the best results. Those propagated from eyes this spring are the most suitable for the purpose; with these I never knew a failure to occur; but that cannot be said respecting those grown in pots the preceding season, cut back in autumn, and planted while making their second year's growth. The latter are generally stronger than the former, but a healthy shoot, 4, 5, or 6 feet in length, with abundance of fresh, fibrous, uncoiled rootlets, makes a substantial and sure formation for immediate and future success. The exact time to plant is not of much importance. It may be done now or any time between this and the middle of

July; but, of course, where the space is empty and the Vines ready, there will be nothing gained by waiting. Vines raised in boxes and root-pruned by cutting the soil and roots into squares, as previously advised, are best for this sort of planting, as they can be lifted and planted without ever being placed in pots, which sometimes interferes with the right direction of the roots. Those propagated in pieces of turf have the same advantage. If the plants have been confined to pots, which is a common way of growing them, the ball and roots need not be much disturbed in planting. Any which have begun to take a circular course should, however, be uncoiled and placed in such a direction as to enable them to extend readily into the border. Planting may be done in the same way as that recommended some time ago for one-year-old canes. Watering must be punctually attended to in order to prevent the foliage from flagging; and should extremely sunny weather set in, a shading of thin canvas should be used during the hottest part of the day. With a little attention, the whole matter may be performed without the Vines sustaining the slightest check, and by autumn they will be a twelvemonth in advance of what they would have been had they been retained in pots this season and planted out next spring. Among Black Grapes for a small house, Black Hamburgh and Black Alicante are most suitable, and among white kinds Duke of Buccleuch and Trebbiano. The first named, both black and white, will ripen with little attention by the end of June, and the other two will keep in good condition, if protected from frost and damp, until February. For a mixed early house, on a larger scale than that just alluded to, Black Hamburgs, including Muscat Hamburgh grafted on the common kind, are most suitable; and, among white sorts, Duke of Buccleuch, Duchess of Buccleuch, Foster's Seedling, Royal Muscadine, and Buckland's Sweetwater. For a late mixed house, Lady Downes, Alicante, Gros Colman, Barbarossa, Mrs. Pince, and Black Prince are the best black varieties, and Pearson's Golden Queen, Muscat of Alexandria, Syrian, Trebbiano, and Raisin de Calabria, the best white sorts. The first house may be made to furnish ripe fruit from the middle of May to the end of September, when the late Grapes will maintain the supply in a moderate way until well into spring. Some dislike growing many varieties in one house, but some of the finest Grapes in the country come from houses planted with miscellaneous kinds. Where many Vineries exist each house may be planted with a different variety, but that is the exception rather than the rule.

Pines.—In addition to the insects mentioned at p. 327 as being injurious to the Pine, ants, which are plentiful in many places, are often troublesome in the case of Pine fruit. They do not meddle with it while green, but when ripe they either make holes for themselves to get into the heart, or enter by the rents which frequently occur in over-ripe fruit, especially in the White Providence and Prickly Cayenne varieties, and it is difficult to get them cleared out when once they get established in such quarters. Their numbers may be greatly thinned, however, by placing a few saucers containing treacle or honey near their runs. Where such enticing traps are employed they seldom pay much attention to the fruit. A sponge soaked in either of these sweets serves the same purpose, and when filled with ants the latter may be destroyed by immersing them in hot water.—J. MUIR.

THE WOODLAND.

Yon woodland, like the human mind,
Hath many a phase of dark and light;
Now dim with shadows wandering blind,
Now radiant with fair shapes of light;
They softly come, they softly go,
Capricious as the vagrant wind,—
Nature's vague thoughts in gloom or glow,
That leave no airiest trace behind.
No trace, no trace; yet wherefore thus
Do shade and beam our spirits stir?
Ah! Nature may be cold to us,
But we are strangely moved by her!
The wild bird's strain, the breezy spray,
Each hour with sure earth-changes rife,
Hint more than all the sages say,
Or poets sing, of death, and life!
For, truths half drawn from Nature's breast,
Through subtlest types of form and tone,
Outweigh what man at most hath guessed,
While heeding his own heart alone.
And midway betwixt heaven and us
Stands Nature, in her fadeless grace,
Still pointing to our Father's house,
His glory on her mystic face!

—PAUL H. HAYNE.

THE FLOWER GARDEN.

CLAPHAM'S STRAIN OF MIMULUSES.

I HAVE now in flower a number of plants of this robust and fine strain of Mimuluses. They were sent me, in the form of small cuttings, early in the year; but they are now about 12 inches in height, and as much in diameter, having large foliage and stout erect stalks. The flowers are large and exceedingly beautiful, with markings that rival the showiest forms of the *Calceolaria*. Some have yellow grounds, others white, and the markings vary from specks of maroon to blotches and belts of deep maroon-crimson. I can best compare the flowers for size with those of the single *Petunia*, which they greatly resemble, but far out-rival in gorgeousness. These Mimuluses are so fine in appearance, that they merit cultivation even as show plants. My plants of them are now turned out of pots into a cold frame, and are afforded, in rough weather or on cold nights, the protection of the lights, and during the day, if needed, a slight shading; but, if dull quiet weather prevails, they may be exposed altogether, and in this position they are doing wonderfully well. Very shortly I shall plant out a large bed of several hundred plants of them in the open ground, to test their usefulness for summer decoration; and I am in hope that they will thrive and answer well. When grown under glass, Mimuluses delight in a cool temperature, and in an abundance of moisture; indeed, in habit of growth and manner of rooting from the side shoots, they resemble the *Water-cress*, and might be almost termed semi-aquatic. Seeds of them sown in a pan and placed in an ordinary greenhouse-temperature will germinate freely, and these will produce plants to flower by the middle of May. Cuttings of them should be put in in the autumn to maintain the stock through the winter, and these will afford an abundance of fresh cuttings for propagation again in the spring. When well rooted, the plants may be potted into 48-sized pots, and, later in the season, from these into 24-sized pots, in which they will make fine specimen plants. If circumstances will admit, the pots would be better, if set on ashes; but, if they must be placed on shelves, it is desirable that saucers should be used, as the roots are gross feeders, and like an abundance of moisture. When the pots are well filled with roots, a little weak manure-water may be given with advantage.

A. D.

Unmown Grass Margins.—

Instead of the usual prim Grass margin and strip of bare dug earth, I find it much better to allow the Grass to grow freely for a few feet around the margin of the shrubs, like a piece of wild meadow. Given proper preparation of the soil at first and established shrubs, one may grow in such garden meadows many of the most beautiful hardy plants, and they will look lovelier in such a position than in the ordinary prim borders or beds. This plan is best with a shrubbery irregular in outline, and with well-grown shrubs boldly relieving each other, the Grass running in around them here and there, and forming little bays. The soft effect of the long Grass amidst the flowers, and of the "Silver-spoons," as the children call the flowers of the various Grasses, seen against the dark-leaved shrubs, are happy additions to the charms of a quiet garden. The Grass need not be mown till it begins to fade in summer or early autumn, by which time both plants and Grass may be cut down

without injury. Great numbers of bulbs and hardy plants make and ripen their growth in spring and summer. Where Asters and autumn-blooming plants are placed in the wild garden, it is, of course, indispensable to select positions that need not be mown at all.
—ALFRED DAWSON, *The Cedars, Chiswick*.

A PARTERRE IN THE SEVENTEENTH CENTURY.

THE accompanying engraving represents the plan of a parterre at St. Germain-en-Laye, designed by Boycran in 1653. It is a fair example of one of those old gardens which disfigure, even to the present hour, many a country seat on the Continent. This style of scroll-gardening was revived in this country by Mr. Nesfield; but it is not destined to have any real success, either here or elsewhere. It is almost impossible to arrange plants in such gardens so that they may prove permanently satisfactory and interesting; and we doubt not that most of them, new and old, will one day or other share the fate of the abolished scrolls in the Royal Horticultural Society's garden at South Kensington. Contrary as this style is to modern notions of garden design, we nevertheless think it well to give two well-engraved illustrations of it (from Didot's "*Manuel de l'Amateur*"). A dozen years ago some gardens of this kind were being made, and it was not unusual to hear it spoken of as a new style; though, as the illustrations now given, and many others will show, it is as old as it is useless and ill-adapted to modern requirements.

Parterre at St. Germain-en-Laye.

Planting the Flower Garden.—

The time has again arrived when this must be done, and the transfer of the plants from their winter and spring to their summer quarters should now be accomplished. To set the plants upright, and give them a good hold upon the ground, is the first step towards making them grow freely and causing them to cover the garden with beauty. Neglect to take this precaution, and failure probably will ensue. Many of what we call bedding plants, for want of a better name, have their roots compressed into hard balls or a matted mass of roots and earth. The roots have been accustomed to a high state of compression, when suddenly they find themselves in a soft bed of earth, as unlike the old compressed state as can be. The consequence is that they often refuse to grow. The best remedy for the severe check to growth resulting from the roots refusing to bite the new soil is to slightly disturb and loosen the compressed balls, and press the new soil firmly against the roots. The boot-heel of the old planters was a reckless, heartless instrument of root torture; but it had one merit, it made the earth firm, and those roots that escaped destruction fastened on the new earth at once. Firm pressure with the hand, to be supplemented by the consolidation of a heavy artificial watering answers admirably. Again, plant deeply. Most bedding plants may be put in, say, 2 inches lower than they have been in pots; the only exceptions are some of the more delicate *Pelargoniums*, which seem as sensitive as to their "collars" not being buried as if they were rare *Conifers*; but the usual run of bedding plants root upwards as well as downwards and to the side, and may safely have 2 inches of friable soil over the top of their roots. This layer of earth wards off drought at first—a point of great importance; and by the time the leaves take this

duty the whole of it will be occupied with surface feeders. Finally, plant thickly and keep reserves in hand in case of accident. An average of from 6 inches to a foot is suitable for most bedding plants. Sub-tropical plants are different, and will need from 2 to 6 feet to exhibit their goodly proportions. It is easy to thin flower beds, but almost impossible to patch them up, by adding to them, without marring the symmetry of form or colour of a well-filled flower garden. Therefore, plant thickly and thin quickly, if need be, and of course none but healthy plants ought to be planted.—F.

The Evening the best time for Transplanting Wild Flowers.—I found out long ago, quite by accident, that the best time for transplanting wild plants was the twilight hour. I was making a bank of wild flowers at the bottom of my garden, and as I drove home one evening through a shady lane I saw some fine Fox-glove plants (I always carried in my country expeditions a small basket and large knife), and as all those my servant planted the previous week had faded, I took up a fresh stock and put them in directly I got home. They thrive well, so did every other small delicate wild flower I had collected in the same ramble; whereas, those put in the ground during the morning always died, despite better soil, careful watering, and shade. I also noticed the same thing in regard to Lemon Thyme, which is a capricious kind of herb at the best of times, and one about which the Welsh are superstitious. I never, however, knew it fail to take root if transplanted in the twilight.—H. E. WATNEY, *Upper Norwood*.

BEE FLOWERS.

THE following is a list of plants suitable for bee culture, excluding those commonly grown in the kitchen garden and orchard, compiled by Dr. Münter, Director of the Botanic Garden of Greifswald:

I.—From March 1 till the middle of April.

Erythronium	Corylus	Sambucus	Aubrietia
Dens-canis	tubulosa	racemosa	columnæ
Scilla	Primula	Cornus	deltoidæa
amœna	officinalis	mas	microstyla
Galanthus	Lamium	Ribes	Corydalis
nivalis	maculatum	sanguineum	cava
Leucojum	Pulmonaria	Viola	solida
vernum	officinalis	odorata	Eranthis
Crocus	Symphytum	Saxifraga	hyemalis
vernus	orientale	cæspitosa	Helleborus
Daphne	Petasites	hypnoides	niger
Mezereum	niveus	Arabis	
	officinalis	alpina	

II.—From the middle of April until the end of May.

Taxus	Primula	Fraxinus	Geranium
baccata	officinalis	Ornus	phæum
Picea	Auricula	Cornus	Viola
alba	Galeobdolon	mas	odorata
Erythronium	luteum	Ribes	Arabis
Dens-canis	Lamium	sanguineum	alpina
Scilla	maculatum	aureum	Aubrietia
amœna	Salvia	Saxifraga	deltoidæa
Hyacinthus	pratensis	hypnoides	columnæ
orientalis	Symphytum	cæspitosa	microstyla
Ornithogalum	orientale	crassifolia	Barbarea
nutans	Anchusa	Amygdalus	vulgaris
Fritillaria	officinalis	nana	Lunaria
imperialis	Myosotis	communis	rediviva
Galanthus	sylvatica	Persica	biennis
nivalis	Petasites	vulgaris	Corydalis
Leucojum	officinalis	Prunus	cava
vernum	niveus	armeniaca	solida
Crocus	Taraxacum	Mahaleb	Helleborus
vernus	officinale	Orobis	foetidus
Polygonum	Sambucus	vernus	Adonis
Bistorta	racemosa	Æsculus	vernalis
Daphne		Hippocastanum	
Mezereum			

III.—From the beginning of June till the end of July.

Allium	Salvia	Valeriana	Ruta
Schœnoprassum	pratensis	officinalis	graveolens
Fritillaria	verticillata	Diervilla	Dicamnus
meleagris	Betonica	canadensis	Fraxinella
Lilium	officinalis	Lonicera	Althæa
Martagon	Melittis	Periclymenum	officinalis
Asphodelus	Melissophyllum	Caprifolium	rosea
luteus	Origanum	Cratægus	Reseda
Polygonatum	creticum	coccinea	odorata
officinale	Onites	nigra	Sinapis
multiflorum	Digitalis	lutea	alba
Iris	purpurea	spinosissima	nigra
graminea	ambigua	Fragaria	Isatis
germanica	lutea	chilensis	tinctoria
pallida	Veronica	grandiflora	Papaver
Sibirica	latifolia	virginiana	somniferum
Polygonum	Polemonium	Cytisus	Mahonia
Bistorta	cœruleum	Laburnum	Aquifolium
Rheum	Syringa	Robinia	Aquilegia
undulatum	vulgaris	Pseud-Acacia	vulgaris
Rhaponticum	persica	Pavia	Thalictrum
Populus	Centaurea	flava	flavum
balsamifera	Scabiosa	carnea	aquilegifolium
Armeria			
maritima			

IV.—From the end of July till the middle of September.

Anthericum	Borago	Sanvitalia	Spiræa
ramosum	officinalis	procumbens	hypericifolia
Gladulus	Cerithe	Ageratum	chamædrifolia
floribundus	major	mexicanum	Rubus
gandavensis	gymnandra	Helenium	odoratus
Lilium	Hydrophyllum	pumilum	Rhus
candidum	virginicum	Silphium	typhina
Polygonum	Phacelia	amplexicaule	Balsamina
Sieboldii	congesta	Cephalaria	hortensis
Cannabis	Nolana	transylvanica	Linum
sativa	paradoxa	Scabiosa	perenne
Statice	Convolvulus	lucida	Melanthus
Limonium	tricolor	atropurpurea	major
Lavandula	Ipomœa	Sicyos	Lavatera
officinalis	coccinea	angulata	trimestris
Dracocephalum	Asclepias	Bryonia	thuringiaca
moldavica	syriaca	alba	Kitaibelia
Salvia	Campanula	dioica	vitifolia
æthiopis	Medium	Heuchera	Kœltreuteria
hispanica	pyramidalis	americana	paniculata
Monarda	carpatia	divaricata	Reseda
didyma	Lobelia	Sedum	odorata
punctata	Erinus	Fabaria	Hesperis
barbata	Solidago	Portulaca	matronalis
Kalmiana	virga-aurea	oleracea	Bunias
Teucrium	Senecio	Lythrum	orientalis
chamædrys	sarracenicus	salicaria	Macleaya
Leonurus	Helianthus	flexuosum	cordata
Cardiaca	annuus	Godetia	Delphinium
Pentstemon	argyrophyllus	albescens	Ajaxis
barbatum	Tagetes	Clarkia	grandiflora
Nicotiana	patula	pulchella	Nigella
rustica	Echinops	elegans	sativa
Tabacum	exaltatus	Enothera	damascena
macrophylla	sphærocephalus	Lamarckiana	hispanica
Physalis	Centaurea	Epilobium	
Alkekengi	moschata	angustifolium	

ROTATION IN FLORICULTURE.

MUCH has been written in regard to the value of a rotation of crops upon the farm, and I am inclined to think it is just as essential in floriculture. Without attempting to discuss the theories advanced in regard to the exhaustion of certain elements in the soil by certain plants, or the poisonous excretions of others, I think, as a source of variety, rotation may be introduced into floriculture with beneficial results, and I have in my mind certain country gardens situated near a road that I have travelled for a great number of years, all of which would be much improved by a rotation or at least a variation of crops. It appears to me that the same dozen or more of Zinnias, large double Marigolds, clump of Hollyhocks, two or three crimson Petunias, and perhaps a half dozen scarlet Pelargoniums, have occupied the same spot every season during the period named. Now I have no objection to these good old flowers, but to see them in the same identical spot, "for ever and ever," without the least change of position, becomes painfully monotonous. To see a single row of tall, slender Zinnias, or big double Marigolds, or plants of the same, scattered here and there among border plants, is enough to make one feel lonesome, through sympathy, but to see the same inartistic arrangement repeated for half a lifetime in the same garden, is enough to make one wish there was a society to prevent cruelty to plants, as well as animals. While I am about it, perhaps I may venture to suggest to my neighbours and the rest of mankind, that it is possible to make a change in the appearance of one's garden every year without any change in the kinds of plants cultivated. The Coleus this summer may be planted where the Pelargoniums were last, and the Petunias in the Verbena bed, and so on through the entire list. These changes in arrangement will doubtless strike your old visitors as a decided improvement upon that of last year; besides, a change in the soil may be very beneficial to the plants. Next season the reverse of this may be adopted if no better arrangement can be devised, thereby securing rotation and variation in appearance without incurring any extra expense.

Do Some one thing Well.

In gardening, as in many other occupations pursued for pleasure or profit, there is a tendency to spread capital and labour over too large an area to ensure anything like perfection in any one thing. The mistakes made by the amateur florist are usually of a similar nature to those who commence studying natural history with the expectation of going over the whole field very thoroughly, but find, to their dismay, that a lifetime will not suffice for investigating the members of many a single genus or family of plants and animals. Many take more pride in the number of species and varieties of plants cultivated in their gardens than in the quality or perfection of the same, which I think is a mistake, leading to more disappointments than true progress. Better grow a few plants well, than many indifferently, is a far better motto for professional as well as amateur florists. To use a common phrase, a person, to acquire great success, must make

certain plants a "hobby," devoting extra care to their culture in order to ensure extra results. I know that it is very difficult to make a selection of a few really good kinds of plants, when there are so many named in our seedsmen's and florists' catalogues, and perhaps all equally desirable under certain circumstances; still perplexities on this score can readily be avoided by following the "hobby system," that is, making a few a speciality each year, or for a succession of seasons until one has thoroughly mastered the difficulties which may appear in this matter. Some of the best displays I have ever seen of certain classes of plants, were produced by this plan. One of my neighbours for the past two or three years has made the culture of Petunias a hobby, and another pays especial attention to the Pelargoniums; the success in both instances is a marvel to those who spread an equal amount of skill and labour over a greater number of kinds, and less upon any particular genus. Of course neither of the persons referred to omit the culture of everything else except their specialities; but the plants named receive the largest share of attention, and the results justify the expenditure. From my own experience, I conclude that this plan of special culture of a few kinds of plants at a time will give greater satisfaction to the cultivator than the more usual one of attempting to introduce everything which may be highly recommended. There are, it is true, a few kinds of plants which are always desirable, like the best Roses, hardy herbaceous plants, and ornamental shrubs; but among the annuals, biennials, and tender "bedders," there is abundance of room for carrying out our hobby to an almost unlimited extent.—Correspondent "Moore's Rural."

Triteleia uniflora.—For Winter and Spring Decoration, this well deserves a place in the front rank among winter and spring-flowering plants. I know of no other flowering bulbous plant that continues to blossom so long, commencing, as it does, about the middle of January and keeping up a succession of handsome pale blue flowers until May. The blossoms are about 1½ inches in diameter, and are borne on stems 9 inches or so in height, well thrown up above the foliage, rendering it admirably adapted for bedding purposes, edgings of beds, masses or clumps for mixed borders, and shrubberies; in fact, it is suitable for any situation, and thrives well in any ordinary garden soil, requiring no protection from frost. For bedding purposes, the bulbs should be planted in October or November, about 2 inches apart, and 3 inches deep. For borders, make a drill 3 inches deep and 3 inches wide, plant the bulbs in two rows, 2 inches apart, and 2 inches row from row. Where it is convenient to let them remain in the beds undisturbed year after year they increase rapidly, and produce flowers in great profusion. This *Triteleia* is also valuable as a pot plant, either for conservatory or window decoration, during the winter months when flowers are scarce. For this purpose, plant from six to twelve bulbs in a pot, according to the size required, and place them in a frame or greenhouse in September or October to flower from December to March.—W. BROOKS, *Weston-super-Mare*.

The Petra Plant, or Spanish Dagger (*Yucca longifolia*).—Professor Buckley, in "Our Home Journal," states that this resembles *Yucca aloifolia*, except that *Y. longifolia* has leaves nearly one-third longer, and a larger and more showy bunch of terminal flowers; besides its lower leaves are often pointed downwards. It is quite common in Western Texas, west and south-west of San Antonio, where it often attains the height of 15 and 20 feet. It is also found in the mountainous region of San Saba and Burnet Counties, where it is smaller—seldom more than 10 feet high. Late in March and early in April it has a large terminal bunch or raceme of white or creamy-white flowers, each of which is about 3 inches in diameter. It was first described and named in the proceedings of the Academy

of Natural Sciences of Philadelphia, in 1861, and is now admitted by botanists to be a very distinct species.

New Tea Roses.—In a recent election of Roses, Catherine Mermet, was placed, by a large majority of electors, amongst the best twelve Roses known; and that it is one of the very finest varieties we have there can be no sort of doubt. Probably, if all the good qualities it possesses are taken into consideration, it will be acknowledged to be the best of all the Teas. It is large, of the finest form, constant, and floriferous. As a pot plant it is a good healthy grower, and makes sufficiently strong though not large wood. Probably it would be a more robust grower in the open air budded on the Briar, which suits most Teas better than any other stock. Though the blooms vary more or less in depth of colour, the prevailing tint is flesh-coloured rose, with a dash of yellowish-buff. There have been several fine additions to the Tea-scented section within the last two or three years. The cream of these are probably comprised in the following:—Amazon, Anna Olivier, Catherine Mermet, Cheshunt Hybrid, Duchess of Edinburgh, Madame Bérard, Madame Camille, and Madame F. Jamin. Amazon does not seem to be much known, but it is a good and distinct flower, with a long pointed bud, which opens well, and is fine, bright, clear yellow in colour; it is a good healthy grower as a pot Rose, and flowers freely. Anna Olivier is a

first-rate flower, of good size; the petals are creamy-white, their base deep rose; it is most distinct and pleasing, and is a healthy grower. Cheshunt Hybrid and Duchess of Edinburgh are dark red Teas; the first has the better form, the Duchess is rather brighter in colour, but both are good and valuable additions to the Tea section. Madame Bérard may be shortly described as an improved Gloire de Dijon, which is not saying a little in her favour. Madame Camille is sometimes extremely fine, but it is a somewhat uncertain variety; if it could be always depended on, it would run Catherine Mermet very close. Perhaps one of the most distinct new Tea Roses we have had for some time is Madame F. Jamin, a small Rose, indeed, but most beautiful; in colour it is deep orange-yellow, inclined to copper colour; in habit it is robust and healthy, and it is most floriferous; as a button-hole Rose it is the best of all.—"Florist."

Rhodanthe Manglesii fl. pleno.—A double-flowered variety of this elegant little Composite, already so popular,

cannot fail, if constant in its character, to attract the attention of the horticultural public. How far this double character is fixed, I am unable to affirm from my own experience, but the seed is stated on respectable authority to yield thirty to forty per cent. of double flowers, and may reasonably be expected to become more fixed with each season of cultivation. In a lithograph sent out by the introducer, the entire body of yellow disk florets is represented as transformed into rosy ligulate florets, resembling the ray-like inner scales of the involucre.—W. T.

Double White-flowered Clematis.—I have sent you a bloom of a Clematis for inspection which is said by all who have seen it to be the best white kind in cultivation. It is a free bloomer and does not grow at all large. Perhaps you will kindly give your opinion of it and advise me as to the best way of propagating it.—W. PALMER, *Holyhead Road, Handsworth*. [The bloom sent is like that of *C. Fortunei* or *Lucy Lemoine*. Your plant may be increased by being layered or grafted on *C. Flammula*.]

Moricandia arvensis.—I should be glad to learn the European distribution of this local plant. I met with it in the Riviera in January last, in the neighbourhood of Ventimiglia, beautifully in flower. It belongs to the Cruciferae, and would seem to be nearly allied to the genus *Brassica*. The flowers are deep lilac, the calyx itself being coloured; the leaves are glaucous and stem-clasping; the pods are four-edged, the seeds slightly winged, and arranged uniseriably in the pod. Reichenbach, in his "Flora Excursoria," states that it occurs in Liguria, especially round Ventimiglia and Nice. Wood, in his "Tourist's Flora," also mentions Ventimiglia as a locality for the plant, though he adds that it is found in Provence and Sicily.—PETER INCHBALD, *The Lodge, Hovingham, York*.

Parterre in the time of Henri IV. of France (see p. 403).

TREES AND SHRUBS.

TREES IN THE WESTERN COUNTIES.

MANY, in giving an account of their rambles through the valleys and woods of Hereford, Gloucester, and Worcester, have described the ancient trees in these counties, and notably amongst others the great Eastwood Oak upon Lady Emily Foley's property, but the subject is not yet threadbare. At this season of the year, when fruit and other trees are one mass of bloom, the beauty of the landscape, and the large amount of historical interest that attaches to many of the natural objects in the counties just named, will repay those who have time to wander at their leisure through woodland scenes that rival the most beautiful in the kingdom. Leaving the Eastwood Oak on the left, and bearing to the right from the Hereford and Ledbury road, some finely-wooded country is passed through; but it is not until one comes to the parish of Dymock, in Gloucestershire, that an opportunity is afforded of measuring some of the fine Oaks and Elms which may be seen growing there in all directions—some in hedge-rows, and others standing isolated in the midst of fields. One growing in the centre of a meadow belonging to Mr. Thackwell, was 24 feet 6 inches in circumference. The village of Dymock is said to have derived its name from the colour of the wood of the Oaks grown about that part—the name being, in fact, a corruption of the words "dim Oak." Passing on through Donnington, there are still some fine timber trees—one Elm, on Mr. Webb's property, being nearly 30 feet, and an Oak some 20 feet in girth. Near this are groups of Scotch Firs on the Haffield estate, which constitute land-marks for miles around. They were planted to form screens on the east and west boundary of a rising knoll where, generations ago, a Vineyard existed—and even now one can trace the terraces where the Vines were planted. So far as I can judge, the space between the two groups is about 12 acres in extent. Cherries now occupy the place of the Grapes; but the spot still retains the name of the Vineyard Bank. In the old farm buildings, there was a wine-press, so there can be no doubt that, in former times wine was made from the Grapes grown there. These groups of Firs are certainly very fine, especially those of the eastern group which numbers over forty trees, many of which would furnish quite 100 feet of timber. They are from 90 to 100 feet high, and have 60 feet of a clear trunk to the branches. I took the girth of two; one was 8 feet, the other 8 feet 4 inches in circumference. From this bank you get a fine view of part of the three counties; also, a little to the east of this, is Haffield Camp, considered to be an outpost of the Roman camps, one of which is at Wall Hills, near Ledbury, 3 miles in a north-west direction, and the other at Bransill, 3 miles in a north-east direction; the three forming an equilateral triangle. Though planted with timber and ornamental trees, you can still trace the outlines of these ancient military positions. This also happens to an interesting neighbourhood for geological research. In Haffield Park the pebbly shore of an ancient sea-beach is to be seen, and instances have not been wanting of the discovery of those strange and mysterious boulders, which differ in every respect from the surrounding formation, and which science tells us were ice-borne from other parts, at an epoch when our waters were those of the polar sea, and our animals and flora those of the arctic circle. Growing near this I found a specimen of the true *Quercus sessiliflora*, measuring in girth 16 feet. R.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Berberis Darwinii.—This, when in bloom, if planted by the thousand, as it is here, gives a finished appearance to the shrubbery. Pegged down, it also makes a brilliant bed at this time of the year.—A. HENDERSON, *Thoresby, Notts.*

Pyrus (Malus) floribunda.—Amongst hardy flowering shrubs this stands pre-eminent just now; it should be used largely in shrubbery borders, as it flowers in the form of small plants, and is not at all particular as to situation. A large plant here is surrounded by tall Oaks, and is just now one mass of bloom.—A. HENDERSON, *Thoresby, Notts.*

Colletia horrida.—Flowering specimens of this spiny and somewhat formidable-looking shrub have been sent to us from Belgrove, Queenstown, by Mr. Gumbleton. Its little pink and white bell-shaped flowers, borne in dense heads, give it, when in blossom, a striking appearance, and render it worthy of more attention than it generally receives.—Q.

Salix rosmarinifolia.—This is a Willow worthy of a place in the front of shrubbery borders; it was in full flower during the last days of April. Its catkins, which are of a rich golden colour, are produced in great profusion, and it makes a fine associate for such shrubs as the Flowering Currant, the foliage being distinct and beautiful.—OBSERVER.

New Zealand Trees.—The climate enjoyed by New Zealand trees is a still and moist one, without frost; and give them that, they will grow almost anywhere. I tried repeatedly to grow the beautiful Rimer (*Dacrydium cupressinum*) as a detached tree, but it always grew sickly until it was planted amongst a thick mass of other shrubs and kept from the wind and sun.—H. W.

THE GARDEN OF ALCINOUS.

HOMER, in his sublime works, has left us what are evidently faithful descriptions of the gardens of Greece in heroic times, and, amongst others, of "that of Alcinoüs, King of the Phæacians, which was said to have been several acres in extent, and surrounded the palace. It was encircled by a hedge, and in it many kinds of trees grew—the Apple, the Pear, and the Orange, charming to the eye and scented, as well as the Fig and the evergreen Olive. These trees, in winter and in summer, were invariably laden with fruits, some of which were developing from the bud whilst others were ripening. Flowers in the vineyards were mingled with the Vines. The garden was bounded by a plot, where the greatest order reigned, and where, throughout the year, the cultivation of numerous plants was carried on. Two fountains were in the garden, the one serving to water the soil, the other, flowing in the direction of the palace, was for the use of the citizens. These were the gifts with which the gods endowed the dwelling of Alcinoüs." When the Greeks had reached that state of civilisation which was never equalled by any race of antiquity, they did not fail to learn from their rivals, the Persians, their system of garden management, which was sufficiently good to elicit the warmest admiration of Xenophon and Lysander. It is not to be wondered at that the Greeks sought to imitate that which appeared so wonderful to them. In applying their skill to this kind of work, they could not equal the luxury of the Persian gardens, but they could show that they were superior to their rivals in elegance of taste. It does not appear, however, that they devoted themselves to horticultural art in the same manner as they did to architecture, and their historians speak of no one garden especially worthy of being remarked. The Greeks, at the zenith of their prosperity and civilisation, were always more celebrated for their architecture than for horticulture, and the partial development of the art of gardening in ancient Greece is to be attributed to a variety of causes, as, for example, to the limited extent of territory, and, again, to their manners and customs, and to their political and social state. These small states, for the most part, had essentially democratic constitutions—no kings, few wealthy people, none of the magnificent palaces to which gardens are usually attached. It is, however, probably to Greece that we must look for the first instance of public gardens, created by the authorities for public use, such as those of the Academia and of the Lyceum at Athens.

Propagation of *Garrya elliptica*.—I have frequently used the flowers of this plant in the way spoken of by Mr. W. Divers (p. 322), and I find them very useful. After repeated trials, I think that the best way of striking the cuttings is to get some good sharp red sand, and with it make a solid bed, 9 or 10 inches thick, raking the top level, and pressing it smooth with the back of a spade. Then procure some good well-ripened shoots, and make them into cuttings, 6 inches long, taking care to give them a clean cut under a joint. Cut off all leaves except three or four of those at the top, make a nick 4 inches deep across the bed of sand with a spade, and put the cuttings in 3 inches apart; press the sand firmly round them, and again level the top. Proceed with the next row, 4 inches apart, in the same manner until all are put in. Place over them hand-lights, or a shallow frame, and keep them close, except in mild weather, when they may have a little air once or twice a week to expel dampness. Place good thick mats over the glass in frosty weather; and, during the warm days of spring, give them air as early in the morning as possible, sprinkling them slightly when the sun breaks through, and then closing and shading them, to prevent their being scorched. As spring advances, and they are safe from frost, remove the lights in the evening, and give them water in the morning if required; then replace the lights, and shade as before. This treatment may be carried on through the summer; and when the hot days are over, the plants will bear free admission of air. Throughout the winter, remove the lights, if possible, once or twice a week, and put mats over the glass on frosty nights. In the spring, they may be taken up and potted into large 60-sized pots, three parts of loam and one part of rotten dung and red sand being used. Plunge them in a bed of ashes, where they can be shaded from the sun until they get established, and be protected from spring frosts; after which they may be repotted and plunged in any common garden soil.—C. R. H., *Abbeyle House, Sheffield.*

IDEAL VIEW IN A GREEK GARDEN.

THE FRUIT GARDEN.

FRUIT TREE CULTURE ON A LARGE SCALE.

By C. BALTET, Troyes.

FOR some time past there has perhaps been too great a tendency on the part of fruit growers to regard merely beauty and regularity of form in their trees. Their chief desire is to secure a handsome tree, well proportioned and symmetrical, its fruit-bearing capacity being apparently a matter of minor consideration. The tree that does not naturally answer the requirements of its owner in this respect is tortured, mutilated, and perhaps eventually replaced by another, and thus many years are lost before it is got into a condition to produce good crops, that is, an abundant and constant supply of fruit. Instances, unfortunately, are only too common, where orchards almost abandoned to Nature yield more than the most carefully tended fruit gardens. At present the demands consequent upon a large consumption of fruit are on the increase; I cannot, therefore, too earnestly recommend all who have waste lands under their control to plant them with fruit trees, which will succeed on mountain slopes, in rows along the sides of roads, by river sides, on railway banks—everywhere in fact, where the character of the soil and climate is suitable; and, above all things, care should be taken to plant kinds only which are certain to thrive, and whose produce will have the best chance in the market. When once the kind of fruit for any particular soil has been determined, the different varieties of it to be planted may be selected; and I may just mention that it is of the very highest importance to have hardy, vigorous, and fruitful trees whose fruit will ripen when the market is not overstocked. One often meets with indigenous varieties of fruit, the cultivation of which does not extend beyond the limits of a certain village. Their produce is certain and their sale assured. If their fruit be good they may be used with confidence, supposing always that the orchard to be planted possesses soil and climate of a similar kind. Instead of multiplying the number of kinds of fruit trees for cultivation, we should rather recommend their reduction, unless the object in view is merely the supply of one's own table. In that case, the number of varieties may be enlarged, in order that we may have kinds that will ripen successively throughout the entire season.

The Apricot.

This likes a light, warm, sandy soil and a sheltered situation. It thrives in good garden ground, but dreads a cold, close, water-logged soil. The blooming season is so early, that it needs protection in spring. In France, it thrives admirably in the mountains of Auvergne, in the Burgundy, Lyons, Bordeaux, and Anjou districts; to the northward, on the plains of Triel, near Paris; to the southward, near the shores of the Mediterranean. In Lot et Garonne, the village of Nicole has Apricot orchards on its steep hill-sides that are exposed to the south, but sheltered to the north. These annually produce 100,000 francs worth of Apricots, which are sent to the Bordeaux markets. The neighbourhood of Dijon produces an early Apricot that is much prized for eating. In the market, its rivals are the Apricots of the south and of Algeria, which are more pleasing to the eye, but less satisfactory to the taste, and less sought after by good judges. The best Apricots of French origin are the Gros Saint-Jean, which ripen early; the common sort used in the making of Apricot pies; the Royal, a fruit much used; and the Pêche de Nancy. The latest, but most valuable, Apricot trees are grown as standards, and may be moderately pruned; but, generally speaking, they are left to Nature, no attempt being made to give any particular direction to their branches. Planting them on high-lying ground ensures well-ripened wood. They should be grafted on the Plum. In the south, they graft them upon the Almond and upon seedling Apricots, and very often the Apricot is reproduced by means of seed.

The Cherry.

The Cherry tree, when grafted on the wild Cherry, will thrive in rich cool ground; when grafted on the Mahaleb it will succeed in arid, strong, calcareous soil; and, when grafted on the seedling Cherry, it will thrive in silicious sandy soils, and sometimes in damp ground. It is only swampy, cold, clayey soil that proves prejudicial to the growth of the Cherry. The roots of this tree have but little disposition to strike deeply into the earth; therefore, great depth of soil is a matter of little importance. The situations best adapted to the Cherry are high-lying ground, slopes, and plains, where there is plenty of light and where the air has free circulation. In the vicinity of a forest or confined in a wood the Cherry tree shoots up and produces but little fruit, and that little is exposed to the depredations of birds. Cold localities, subject to fog, are unfavourable to Cherry culture, as are also too warm and dry situations. At Saint Bris, in France, where Cherry brandy is made, Cherries to the value

of £4,000 a-year are grown on less than 230 acres planted with May Duke. Cherry trees should be planted as standards, either in clumps, on plains, or in hilly ground, upon waste lands, and upon railway embankments. All dwarf Cherry trees are grafted in France upon the Sainte Lucie variety. Standards should be grafted upon the wild Cherry for planting in good soil, and upon Sainte Lucies for dry, light, and mediocre land culture. The principal varieties are—The Early English or May Duke, Empress Eugénie, Late English, Montmorency, Reine Hortense, Belle de Chatenay, Black Griotte, Early Guigne, Ohio's Beauty, Rose Bigarreau, Red Bigarreau, and Black Bigarreau. It is not necessary to prune the Cherry tree; occasionally the young sprouts may be cut back, but the stronger and older branches should not be cut. Montmorency Cherry trees in Champagne are, however, pruned decennially without disadvantage.

The Pear Tree.

This likes a good deep soil; dry warm ground is not favourable to its growth, and ground, on the other hand, that is too damp is equally prejudicial to the tree. An open argo-silicious soil, or one of a fertile, ferruginous, light, and somewhat cool character, or where a calcareous rather than a turfy loam is to be found, proves suitable for these trees, always supposing that the top soil is deep and the sub-soil permeable. The Pear tree lives under difficulties in a latitude hotter than that of the south of France. In Algeria it becomes scorched and dried up by the winds of the desert. On the other hand, too cold a climate is inimical to its successful cultivation. In warm countries, therefore, the Pear tree must be planted upon the northern slopes of hills and upon flat open ground; in cold localities it should have a position where it can be reached by the sun's rays—in gorges, for instance, where the air and heat are concentrated, and upon plains at a sufficient altitude to render any fear of stagnant damp needless, but not so high as to expose it to cold currents. As in the case of other fruit trees, its vicinity to a stream of water is favourable to its fertility. The number of varieties of Pears cultivated is very considerable, a fact concerning which it is easy to satisfy one's self by visiting the markets of large towns and country orchards. All over the Continent one meets with a profusion of Pears bearing unknown names and doubtful in quality; all these are not adapted for growing as standards. In some the fruit is too large, or adheres badly to the branches; others require an annual pruning, which it is impossible to apply to full-grown trees. One constantly meets amongst the early varieties some which cast their fruit or which ripen too suddenly; others, on the contrary, retain their fruit till it ripens on the tree. In modern times much attention has been paid to winter Pears for dessert; but good returns can also be had from summer or autumn kinds. They ripen when fruit is much in demand. Keeping Pears are unsuitable for standards, because they are comparatively valueless when bruised. In spite of the importance of the nomenclature of Pears, whose ripening commences at the beginning of June and ends in the spring of the following year, our list of orchard Pears is somewhat short. We must not, however, forget that, wherever good local kinds are to be found, although not mentioned here, they may be made use of, provided their sale can be depended on. One meets with l'Echassery and the Bon Chrétien d'Été in Switzerland, the Forelle in Germany, la Charbonnière in l'Ardèche, l'Épine Dumas at Limoges, la Poire de Prêtre in Champagne and Burgundy, the Deux Yeux in the district of Lyons, the Roussette in the Côte-d'Or, the de Fosse in l'Aube, the Herbin in Picardy, the Torpes and the Mantivelle in Saône-et-Loire, the Bergamotte d'Été in Chartrain, the Saint-Michael Archange at Nantes, the Bési de Quessoy and d'Héric in Brittany, and the Mouille-Bouche at Bordeaux. Amongst extraordinary instances of production, it will be sufficient to state that at Publier, in Savoy, there exists a tree that produces 150,000 Pears every year; near Meaux, a Carrière Pear tree which produces annually Pears to the value of £6; in Cher, a Cogné, which is equally valuable; at Presles, in Brie, there are Rignault Pear trees of which the crop is worth £4,000; at the foot of the Alps, the Royale d'Hiver has produced fruit to the value of £32 from two trees (this case, probably an exceptional one, occurred at Monétier-Allemand, in the Commune de Ventavon); at Varennes-lès-Beaune, a small inferior early tree, with fruit of a bright colour, brought in £4; at Troyes, the product of three trees of Bellissime d'Été brought in £20; at Saint-Trond, in Belgium, the Koolstok (Cabbage Stump) produced £4,000 annually in the country, and gave rise to the establishment of a new industry—that of basket-making and the cultivation of Osier-beds. The following is a list of good orchard Pears:

Summer Pears.—Doyenné de Juillet, Citron des Carmes, André Desportes, Espargne, Beurré Giffard, Blanquet, Docteur Jules Guyot, Boutoc Beurré d'Amanlis, Rousselet de Rheims, Monsallard, Madame Treyve, Doyenné de Mérode.

Autumn Pears.—Beurré Hardy, Beurré Superfin, Beurré d'Angleterre, Louise-bonne d'Avranches, Beurré Capiaumont, Beurré Dumont, Marie-Louise, Doyenné du Comice, Emile d'Hyst, Fondante Thirriot, De Tongre, Beurré d'Apremont, Alexandrine Douillard, Figue d'Alençon, Beurré Bachelier, Madame Bonnefond, Triomphe de Judoigne, Beurré Diel, Fondante du Panisel, Beurré Baltet Père.

Winter Pears.—Beurré d'Hardenpont, Passe-Colmar, Curé, Sœur Grégoire, Beurré Millet, Nouvelle Fulvie, Marie Benoist, Doyenné Boissard, Chaumontel, Passe-crassane, Royale-Vendée, Beurré Rance, Joséphine de Malines, Doyenné d'Alençon, Olivier de Serres, Beurré Perrault, Bergamotte Esperen, Doyenné d'Hiver.

Cooking Pears.—Pears for cooking or stewing should find a place in every orchard. They are invaluable in certain culinary preparations, and in this way are used largely in some districts. Amongst the best of this kind are Certeau d'Automne, Messire Jean, Martin sec, Catillac, and Sarrasin. We have not mentioned the Belle Angevine (Uvedale St. Germain's), a Pear that holds the first place as regards beauty, but the last for quality; it is a showy fruit, and keeps well from year to year. It is capable of acquiring magnificent proportions, and succeeds well grafted upon the Quince tree. Thus produced, a fine specimen of the Belle Angevine variety will easily sell in Paris for 16s. In vacant spots in orchards, whether amongst the large trees or in the shape of an orchard fence, it is possible to cultivate a large number of good dessert Pears, and we may add the following varieties, remarkable for their productiveness, their beauty, and their general good qualities; the trees adapting themselves to cultivation either as half-standards or dwarfs:—William, Clapp's Favourite (an American kind), De l'Assomption, Souvenir du Congrès, Van Marum, Colmar d'Arenberg, Nouveau Poiteau, Fondante des Bois, Sucrée de Montluçon, Duchesse d'Angoulême, Beurré Clairgeau, Beurré Six. In favoured situations, or under the shelter of a wall, there may be planted Beurré gris, Doyenné blanc, Crassane, Saint-Germain, Royale d'Hiver, Doyenné d'Hiver, Bon Chrétien.

Pears for making Perry.—Pears for making perry are an important fruit from the beverage they furnish, which is one resource that countries deprived of Vines can fall back upon. It would be difficult to state precisely those kinds most adapted to the manufacture of perry, as they are differently named in each country. We give the names of those most noted in Normandy:—Carisi, de Blanc, de Chemin, de Cheval, de Cloche, d'Entricotin, de Fer, de Hie, de Noir, de Normandie, de Sauge, Gros-Blanc, Gros-Vignon, Gros-gris, Longue-Queue, de Loup, Picard, Sabot, Saussinet, Sirolle, Trompe-Gourmand, &c. The Drying Pear occupies a prominent position amongst the economic productions of Switzerland and Germany. The Kannenbirne, or Etranguillon, is much cultivated there. The slices of dried Pears, called séchons, are used for stewing and for perry. The orchard Pear tree, bearing fruit intended either for dessert, for cooking, or making perry, should be grafted on a seedling, and trained as a standard. It is grafted at the collar, or higher up, either where it is to stand or in the nursery. The tree is left to itself, after having trained the branches for the first year or two. Later on, it will only be necessary to clear the thick branches by annually cutting in those that are etiolated, or incapable of bearing fruit. By this, a more regular fructification is secured, and the vigour of the tree is preserved.

The Apple Tree.

This thrives in alluvial sand, where soil is mixed with silicious clay, and upon soils resting on a granite bed, as well as in those where the turfy humus neutralises the aridity of the limestone. Moderate coolness and a sub-soil sufficiently porous and permeable is favourable to it. The fruit is generally larger in damp valleys than in exposed situations; but has a finer flavour when the trees are grown upon hill-sides, and on flat ground that is not liable to saturation. An excess of moisture, as much as a want of air, engenders canker and grub. An excess of dryness will cause the tree to wither. Land adapted for Wheat in general suits the growth of the Apple. It thrives admirably on the mountains of Auvergne, in the meadows of Normandy, Brittany, and Picardy, and in Flanders, Germany, Sweden, and Russia. The best should be selected for dessert; those of a less superior character for cooking; and those of inferior quality for making cider.

Summer Apples.—Red Astrachan, Rose de Bohême, Borovitsky, Transparente de Cronsels, and Rambour d'Eté.

Autumn Apples.—Gravenstein, Reinette Burchardt, Reinette Grise d'Automne, Belle Fleur, Reine des Reinettes, and Royale d'Angleterre.

Winter Apples.—Doux D'Argent, Belle Fleur Jaune, Parker's Grey Pippin, Reinette d'Anthézieux, Pigeon, Reinette de Cuzy, Reinette du Canada, Reinette Grise, Reinette Dorée, Fenouillet, Reinette Franche, Calville Blanc, Api Rose, Reinette des Carnes,

Renette de Caux, Azeroly Anisé, Reinette Baumann, Reinette Tardive, Clarke's Pearmain, and Jacquin.

Late Apples.—Care should be exercised in selecting late fruiting Apples. In cold countries they escape the inclemency of spring; but, in a warm locality, they have to run the risk of their blossoms being scorched. Of late-fruited varieties there are many. In general, their fruit is hard, acidulated, and chiefly adapted for household use. The following are good, both for dessert and for cooking, and, when needed, they can be used for making cider—viz., Belle des Buits, Bonne de Mai, Courpendu, Cusset, De Jaune, Jean Huré, Locard, Pépin d'Or, Reinette à la Longue Queue, Reinette Clochard, and Saint Bazan.

Cider Apples.—Let us direct attention to the manner of choosing cider varieties. Whenever an Apple, on being pressed, is found to be juicy, it is usually considered to be fit for cider. In the opinion of *connoisseurs*, however, cider is never perfect except it is limpid and clear, of an amber colour, piquant and agreeable in taste, and without any unpleasant odour or acidity. Practical cultivators know that, in order to obtain cider of this description, it is necessary to mix acid, sweet, and bitter Apples together, in the proportion of one part of the first to two of each of the latter kinds. This proportion is based upon the fact that Apples that are acid or sour give an abundance of juice, those that are sweet impart an agreeable flavour, and those that are bitter tend to preserve it. Cider made from either kind separately has its inherent faults. If made from the first-mentioned, it is indifferent in quality, and becomes dark when out of the cask; if from the second, it is of a pale colour, and will not keep; and, if from the third, it is produced in sparse quantities, and is too thick. Mixed, however, an abundance of juice is obtained, which has a pleasant taste, and keeps well. This combination need not be rigorously adhered to; sometimes it is only necessary to make use of sweet and bitter Apples, and the beverage is sufficiently charged with sugar and tannin. The character of the soil and climate may modify this prescription; analysis shows that the quality of the cider thus blended depends upon the just proportion of sugar, mucilage, and malic acids. Science also shows that green fruit contains about six parts of sugar, ripe fruit twelve, and mellow fruit only eight; thus, it will be seen that sound ripe fruit only must be made use of. Often enough this proportion spoken of is settled at the time that the trees are planted. Thus, in Normandy, they plant five Gagnevin Apple trees for one of the Coquet variety, one of Gros Bois, and the mixed crop is sent to the press together. These divisions of sweet, acid, and bitter Apples may be arranged according to the period at which the fruit ripens. Cider Apples are grouped into three seasons—September, October, and November; in each season are found sweet, acid, or bitter fruit; and the crop is combined so as to send to the press varieties differing in flavour, but at the same stage of ripeness. The Apples of the first season, amongst others, are Ambrette, Bonne-Ente, Camoise (acid); Doux-à-l'Aiguel, Rouge-Bruyère, Frangée (sweet); Amer-Doux, Blanc-Mollet, Friquet (bitter). These produce a cider that contains sufficient sugar; and, although decidedly acid, pleasant to the taste. It bears the admixture of but little water, and should be drunk within the year. The Apples of the second season, amongst others De Rennes, Courte Queue, Fleur d'Auge (acid); Gros-Doux, De Rouget, Doux-Evêque (sweet); Cul-Noué, Amer-Rouge, Petit-Ameret (bitter); furnish a good mellow cider, which is in much demand for bottling. The Apples of the third season, amongst others, Glane d'Oignon, Long-Bois, Surette (acid); Marin-Anfray, Rousse, Peau-de-Vache (sweet); Bec-d'âne, De Monnier, Gros-Amer (bitter); are very valuable for making coarse cider. Less delicate than the preceding, the beverage may be kept several years. These remarks may be said to apply to all countries, without taking into consideration existing diversities. For the cultivation of the Apple tree as a commercial speculation, standards upon wild stocks should alone be used. The tree is grafted where it is to stand, or subjected to preliminary training in the nursery. By leaving the branches to take their own direction, the tree assumes a natural development, and it will be sufficient to equalise the strength of the branches when young, and every year to prune or cut back those that are worn out, or are growing confusedly, without causing any wounds that are too severe. Should grubs give trouble, it will be necessary to loosen the earth round the trunk, and pour in lime-water. I have not as yet referred to show Apples. The most beautiful are Amélie, Joséphine, Grand Alexandre, Belle-Dubois, Ménagère. These should be cultivated in clumps, or in a cordon upon a Doucin or Paradise stock. It is possible to make arbours with them, or they may be used in many other ways.

The Plum Tree.

This is one of the least exacting of fruit trees as regards the quality of the soil in which it is planted. Most lands that are fit for cultivation will suit it, provided always that they be not too clayey

nor too damp. It, however, prefers a somewhat mellow soil, with a permeable sub-soil. Its flowers suffer sometimes from late spring frosts, but its cultivation, nevertheless, extends very far north. Immense orchards of Plum trees exist in Europe and in America, and even Africa and Asia are not without them. In Roumania Plum cultivation gives rise to a special industry—that of manufacturing Plum brandy. In Hesse, as statistics show, there are three million Plum trees growing—a number double that of the Apple trees—and these, for the most part, are cultivated by the roadside and in public places. In France, in the Agenais, proprietors obtain for their crops of Plums D'Ente or D'Agen as much as £400. One single firm of Cassaneuil does business to the extent of £160,000 exclusively in Prunes. La Lot et Garonne produced, in 1872, 25,000,000 of Prunes. The Bordeaux markets disposed of £600,000 worth, half being exported. The Sainte Catherine of Touraine, the Mirabelles, and the Quetches of Lorraine, are equally valuable as a means of enriching those who undertake their cultivation. The Reine Claude and Mirabelle, which may be called the common Plum, yield in La Marne and La Meuse fabulous returns. Thus, in 1872, whilst Vitry-le-Brûlé sold £4,000 of Reine Claude, and Sainte Menehould £3,200 worth, the neighbourhood of Sainte Mihiel sent 800 waggon loads to Lerouville. Nor must it be forgot that the Department of L'Aube, the Commune of Baroville, has become rich through its Plum trees, its Grapes, and its Gooseberries, and sells Reine Claudes to the value of £2,000 annually. At the present time the neighbouring villages are imitating the example thus set with success. Like the Apple, the seed of the Plum tree often produces good seedlings, but the most certain mode of propagation is the grafting of good kinds upon healthy and robust seedlings, not upon suckers.

Early Plums.—Favorite Hâtive, Mirabelle Précoce, Jaune Hâtive, Précoce de Tours, des Béjonnières.

Mid-season Plums.—Monsieur Hâtif, Monsieur Jaune, de Kirke, Reine Claude, Mirabelle.

Late Plums.—Reine Claude Violette, Tardive Musquée, Madam Nicolle, Coe's Golden Drop, Mirabelle Tardive.

Prune-Plums.—D'Agen, Sainte Catherine, Quetche, Datte, Jaune Tardive, Perdrigon, Damas, de Norbert.

The Plum tree, when once well-formed, does not require pruning, except so far as the cutting back of branches that are unhealthy is concerned.

General Directions.

Distance Apart and Preparation of the Soil.—The mean distance of standard fruit trees of any kind is calculated according to the probable development of the branches. Thus, from 20 to 32 feet is suitable for Pear and Apple trees; these distances are increased where the soil is unusually good, or in a mixed orchard, in which the trees are planted in masses and not in single lines. The distance between the trees should also be increased if small subjects, such as half-standards, pyramids, or bushes, occupy the intermediate spaces. For a plantation of trees at a short distance apart the soil should be trenched; but, for full-grown trees, the subjects being at greater distances, it will be sufficient to open large holes 3 feet 6 inches wide, and 2 feet 6 inches deep at the least. The more roots the larger of course should be the holes. They should be opened with a spade and the bottom and sides broken up, in order that the roots may not be surrounded by hard soil. Where the sub-soil is inferior in quality take it out; but, if from its depth or nature, this presents difficulties it is better to leave it, and to enrich the top-soil with a layer of some better kind of compost. The best materials for this purpose are vegetable and alluvial soils, turf, the detritus of rivers, leaf mould, sweepings of streets, marl, and similar substances mixed together, until a compost thoroughly favourable to tree life is obtained, for the object of manuring is to supply to the soil that of which it is deficient. These ingredients, mixed with well-rotted dung, is incorporated with soil at least a month before it is wanted for use. Leaving the holes open, too, for some time previous to planting, contributes to the amelioration of the soil through atmospheric action. Where the soil is too wet, it should be drained; and even broken stones placed at the bottom of the holes, and covered with sods, with the grassy sides down, will be of benefit to the roots, and not interfere with the regular drains. Where the soil is naturally good, and of a sufficient depth, manure is unnecessary.

Planting and Pruning.—Planting is best done when the trees are at rest, that is, between the fall of the leaf and the depth of winter. The drier the ground is the later planting may take place. The trees having been removed with care from the nursery, should be examined before being planted. If their roots have suffered from exposure they should be soaked in a mixture of clay, water, and cow-dung, and before finally placing the tree in the ground all mutilated or denuded roots, as well as exhausted rootlets, should be cut

off, and, at the same time, the most vigorous of the branches should be cut back, while such as are useless or badly placed should be cut off altogether. Lightly press the soil after planting, especially if light and porous; stake the tree and water the ground. Plant in clumps or in lines according to the taste of the cultivator. Some annual or biennial cutting-back of the branches will be necessary, at least for a time, in order to properly balance the tree and ensure its fructification. A mulching of dung, Fern, Moss, tan, or similar substances, should be spread over the roots early in spring to prevent evaporation. In warm situations the stems of the trees should also be painted with a mixture of mud, dung, and lime. During the first few years the ground over the roots should be kept clear of Grass and weeds, and every autumn the mulching of dung should be forked into it. In spring a fresh mulching should be put on. When the trees have arrived at maturity this may be dispensed with, and laying the orchard wholly down in Grass will do no harm; if, however, it is thought fit to cultivate it, deep digging should be avoided. The bark of the trees, both of stem and branches, should be scraped where insects are likely to harbour, and Moss, Lichen, Mistletoe, and dead wood should also be removed. Where the trees in an orchard need renovating through being somewhat worn out, the earth round their roots should be renewed. The old bark should be cleaned, and the principal branches cut back to a certain distance from the trunk. The Apple, Pear, Apricot, and even the Plum, may thus be operated on. Instead of cutting the branches removed back close to the trunk, it is preferable not to cut nearer than a foot or eighteen inches of it. The stronger the tree the more should the branches be thus cut in. Rub the wounds over with a mixture of cow-dung and clay. If the variety thus operated on be unsatisfactory, it may be changed by grafting upon it a more valuable kind; in this case crown grafting is best, and the more limbs operated on the better. When the grafts shall have begun to grow freely they should be supported, in order to prevent their being blown off. Where the tree is too old or too defective to be of any use it should be felled, the roots extracted, and before planting another tree in the same place the soil should be renewed.

Fruit Gathering and Storing.

For these operations fine weather is indispensable, and the fruit should be plucked neither too green nor too ripe. Gathered in this state, it gains in quality by being kept, and bears carriage better than when too ripe. In gathering fruit, care must be taken not to injure the branches, or to break the fruit-bearing twigs; with the exception of fruits for cider, Nuts, Chestnuts, Almonds, that are brought to the ground by shaking with poles—a violent proceeding, it will be admitted—the other kinds should be gathered by hand. For this purpose, double or single ladders and hooked switches, to draw the branches, should be used. An instrument, called a fruit-gatherer, is also sometimes employed, by which fruit at the extremities of branches, or inaccessible, is seized. The fruit, when gathered, should be laid gently in a basket covered with foliage, and taken to an airy fruit-room, where they should be placed upon a bed of Rye-straw; soft-fleshed fruits, such as Apricots, Cherries, Peaches, or Plums, may remain in the baskets or upon boards. For this kind of fruit, a moderate temperature in the fruit room is indispensable. Too great a heat will precipitate their ripening, whilst a cold atmosphere will disturb the elaboration of their juice. The dryness of the fruit-room is also a necessary condition; and the removal of diseased or spoilt fruit must never be forgotten. The Apricot should be gathered, when the skin, without being faded, assumes a duller shade; the green part becomes yellow and marbled. The Apricots intended for carriage should be gathered during cloudy weather, before the flesh has lost its firmness. Those used for marmalades, and for similar purposes, should be riper than would otherwise be necessary. If the crop of a tree be gathered all at once, it will be easy to divide the fruit for immediate consumption from that which is intended for carriage. The Cherry should be gathered when fully ripe, and before its colour is tarnished; Griottes may be gathered later, with the exception of those intended for making ratafee; Whitehearts and Guignes will decay if they are not gathered before their skin becomes too highly coloured. The Peach is fit for gathering when its green side gets bright, and the perfume very perceptible. Summer Pears should be gathered as soon as they commence to turn yellow, or to fall. Autumn Pears may be taken from the tree when they can be removed without using much force; they should then be placed in a room in which there is a medium temperature. Winter Pears may be plucked later, but in all cases before white frosts set in. The fruit-room in which they are placed should be kept dark, regular in temperature, and not exposed to damp or frosts. It should be furnished with drawers, one above the other, and with open shelves made of laths. Early Apples require gathering when they are ripe; winter kinds

should be gathered at the end of the season; if allowed to remain upon the tree tender Apples ripen more rapidly; keeping Apples, on the contrary, are improved by being allowed to hang late, that is, if they are gathered before the fall of the leaf. Cider Apples are gathered in the simplest manner; the tree is merely shaken, either by hand or by means of crooked poles, and there is no danger in having them out-of-doors until they are required for pressing. The ripeness of Plums may be known by the strong perfume which they emit, and by the fall of the fruits when the trees are slightly shaken. They should be gathered with care, and those that are injured should be separated from the rest. Choice Plums should be gathered by hand, care being taken not to injure the skin, for a Plum deprived of its bloom loses much of its value.

Packing Fruit.

Fruits should never be gathered during rain, fog, or whilst dew is on them, nor during great heat, and the longer their journey is likely to be the more rigorously should these instructions be carried out. It should not be forgotten that fruits in a close-confined place go on ripening, and in consequence it would be imprudent to introduce any that are in a state of decay, or likely to become spoilt in transit, and precautions should be taken against the introduction into the packing-cases or baskets of substances likely to aid fermentation, such as damp hay, fresh Moss, or green leaves. All fruit that is damp should be wiped dry in the shade before being packed. In conclusion it is desirable with all kinds of fruit—1st, to use moderate-sized baskets or packing-cases (ten of a small size are better than one of large dimensions), and to avoid too great a number of layers of fruit one above the other. 2nd, to fill up the spaces between the fruit with pieces of paper, Grass, Oat-straw, bran, sifted sawdust, or wadding. 3rd, to pad the bottom and top with Rye-straw, with thick paper, or dry Fern leaves. 4th, to close the lid so that it may press lightly but firmly upon the fruit, and thus prevent its being shaken about inside. Choice or delicate fruit should be wrapped in a sheet of paper, silk-paper being used for tender-skinned varieties and ranged in layers in small wooden cases. If many layers are necessary, the toughest specimens should be placed at the bottom.

Keeping Apples Out of Doors.—The "Rural Home" gives an account of an experiment near Rochester in keeping Apples on the ground under leaves. Two bushels of leaves were placed on one bushel of Apples, the whole being partly surrounded by evergreen trees, which kept the wind from blowing the leaves. They were found this spring less decayed than Apples in the cellar, and fresh and fine in condition. There were obviously two or three causes which made them keep well. Contact with the earth gave them moderate and uniform heat from below; the leaves, being stratified, turned off the water and kept out the cold, the frost of very few winters ever reaching through a foot of leaves; and the evergreen trees gave additional protection. If we were covering Apples in this way in an exposed situation, we should want a foot of leaves, held down by evergreen branches; but, surrounded closely by evergreen trees, half that depth of leaves would answer.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Strawberries at Christmas.—I am just now busy potting Keen's Seedling Strawberry plants, forced ones, or what have fruited, into 16-sized pots, in order to try to get them to produce ripe fruit at Christmas. Shall I succeed?—R. GILBERT, *Burghley*.

Watering Strawberries: L. W. B.—It is very desirable that Strawberries should be well watered. Begin watering just after the flowering is at its best, and continue it while the fruits are swelling.—B.

Peach Trees Dropping their Fruit.—What is the reason my Peach trees have lost all their fruit, except a few at the extreme ends of the top branches which have lost their foliage? The trees are good and healthy-looking, and produced a good crop last year for the first time. Can any of your correspondents kindly assign a cause for this mishap?—A. K.

Duke of Buccleuch Grape.—I have often been disappointed in growing new Grapes, but I am happy to tell your readers that this is a splendid variety. I have at this time (May 8th) a Vine of it growing in a 10-inch pot, bearing six clusters of such white Grapes as are seldom seen. The berries are clean (except a single one), of enormous size, of a fine amber colour, and have an exquisite flavour. If Mr. W. Thomson had produced nothing besides this superb Grape, it would have been sufficient to have established his reputation.—R. GILBERT, *Burghley*.

The Phylloxera and the Means of Staying its Ravages.—This has for some time occupied the thoughts of Prof. Dumas, who, after much labour and research, has hit upon an agent which, while being fatal to its insect parasite, is said to be beneficial to the Vine itself. The agent employed by M. Dumas is sulphuric carbonate of potash. The mode of application is in the form of a light dressing over the surface of the soil of Vine border or vineyard, where the salt is soon dissolved by rain or artificial watering, and the solution carried down to the roots, where it destroys the insect, which, the moment it is touched by it, is done for, while both roots and Vine are rather benefited than harmed.

THE INDOOR GARDEN.

CULTURE OF SPECIMEN PELARGONIUMS.

FEW of those who admire splendid specimen plants of Pelargoniums, exhibited at this season of the year, have any idea how rapidly such specimens are got up under good culture, or that only a year before, perhaps, they were but cuttings, or one-year-old plants. Pelargonium growers like to have symmetrical specimens, though they may not be meant for exhibition, but only for the conservatory or perhaps the vases in the house, where they can be seen and admired. It was my duty, at one time, to get up such plants for a noted exhibition, and also for decorative purposes on an extensive scale, and I always adopted the following method:—The cuttings may be put in any time between spring and autumn, but the best time is just after the plants have finished flowering, when the wood is somewhat hard and ripe, which is generally late in June or July, or even as late as August, but the sooner the better; and those who purpose taking cuttings off their old plants should stand them out of doors after flowering, in order, in some measure, to harden the wood. Stout, short-jointed cuttings, about 3 inches long, should be selected. Side shoots that have not formed are best; but, if these cannot be obtained, any of the limbs will do, cutting them about three or four joints in length. These must be cut close below the bottom joint, and inserted singly in 3-inch pots, in a compost of sifted loam, leaf mould, and sand, in equal parts; and afterwards watered and plunged in a frame where there is a slight bottom-heat of 70°; or they will strike, but not so soon, nor so certainly, on the shelf of an intermediate house. Cuttings of what are called "fancy varieties," however, require frame treatment and bottom-heat. When the cuttings are rooted fairly, which will be in about three weeks, they should be lifted out of the bottom-heat, and set on the surface of the bed to harden them a little before removing them to a greenhouse or cold house, for an airy, dry, greenhouse temperature suits the Pelargonium best, and the less fire heat it is subjected to the better; in winter good growers never allow the thermometer to rise above 45° with a dry atmosphere and free ventilation. After the cuttings are fairly hardened off they may be shifted into 4½ or 5-inch pots, first crocking the pots carefully to the depth of about an inch. For this shift the best compost is turfy hazel loam, chopped up as finely as possible with a spade, and to which has been added one quarter of silver sand and charcoal dust and a little well-rotted cow dung or much-decayed hotbed manure free from worms. In shifting turn the plants carefully out of the pots, remove a little only of the surface soil, the crocks at the bottom, and disentangle the roots when they are matted; pot no deeper than before, and fill round with the compost without pressing it very hard; leave half-an-inch for watering, and restore them to their former airy and light quarters, watering them thoroughly, especially if the pots be new. Partial shutting up and dewing with the syringe may be practised on bright days; but in dull warm weather it will not be necessary. The plants will now be growing apace, and the shoots should be pinched and pegged out in opposite directions, but not too flat. This will cause them to break afresh at several places, and the young shoots thus produced must be allowed to grow 3 or 4 inches and again stopped, but without pegging, merely pressing the shoots down and outward with the hand now and then to broaden the head and admit the light until the plants are ready for another shift. The disposition of the branches to break thickly depends upon the light and air they receive as much as pinching, for the Pelargonium is disposed to assume a branching habit naturally. About midwinter, or a little later, the plants will be ready for their final shift into 8 or 9-inch pots, according to their vigour and progress. The same compost as before should be used; the same care exercised in potting, and afterwards the outside shoots should all be pegged down to the surface of the pot. When this is done the plants will, in some cases, be 12 or 18 inches across. The shoots in the centre should also be stopped and pegged outward at the same time. This forms the basis of the future specimen plant. The plants will be green, and keep growing slowly all winter, with a minimum temperature of 45°, and a slight rise during the day in fine weather, admitting a free circulation of air, avoiding draughts, and applying fire-

heat only to sustain the nursery temperature and expel damp. After the last shift, but little pinching will be required, if the plants have been struck early, and are required to bloom in May and June. The broad bottom formed by pegging out the shoots in winter will throw many shoots, and these will make a regular growth, greatly increasing the diameter of the plant. As the season advances, gentle smokings must be given to check greenfly, and syringings in fine afternoons. When the flowering shoots lengthen, the plants should be staked or tied. To give breadth and size, the bottom shoots should be tied down to stakes inserted in the pot, projecting outwardly, and as low as the rim of the pot will permit. The next tier of shoots may be staked out in the same way, or tied down to the others with fine matting, and the next tied to these again, and so on, till the shoots are evenly distributed, and the desired circumference and symmetry are attained; but all training should cease before the plants come into flower. Pelargoniums should at all times have enough water. In winter, very little is required to keep the soil in a moist state, and cloggy wetness must be avoided; but, as the days get longer and drier, the supply must be copious, and not given in dribbles, but in sufficient quantity to soak the ball of the plants thoroughly, until the water runs out at the bottom of the pots, and, just before the flower-buds begin to form, weak liquid manure may be given two or three times a week, and continued till the flowering is over. After this, the plants should be turned out of doors till August, when they should be cut down. **CHEF.**

HAYES'S CINERARIAS.

AMONG the many plant-growing nurseries round London, few are more interesting than that of the Messrs. Hayes, at Edmonton, and

Large Crimson and White Cineraria (Hayes's).

they are particularly notable for a very good strain of Cinerarias. Messrs. Hayes lately sent us a collection of blossoms. Some of these were so remarkable for size, as well as for rich beauty of colour, that we have engraved one of them, exactly life-size. It is scarcely necessary to add that the central and earlier blooms are always much larger than the blooms that come afterwards; but, even bearing in mind the fact that the blossom figured for *THE GARDEN* was one of these early blooms, its size is none the less remarkable.

THE MANGOSTEEN.

MUCH has been written lately in depreciation of tropical fruits. The Apples, Pears, Grapes, Peaches, Plums, and Nectarines of Europe—its delicious Strawberry, and even the pungent flavour of our Gooseberries and Currants, have been exalted, and perhaps with good reason, as delicious realities, while the laudatory descriptions of inter-tropical fruits by Eastern poets have been treated as the airy fabrics of vivid imaginations, and as having no actual foundation in fact. West

India Pine-apples have been pronounced tough and tasteless compared with a Pine grown in England or France; Dates are now deemed insipid; the large, ponderous, handsome-looking Shaddock is found to be but a base-born giant of the Orange tribe, the purest blood of which is found in the delicate little St. Michael's that flourishes in the Azores. There is one, however, among the tropical fruits, which all who have tasted, in the sultry clime of which it is a native, pronounce to be the most exquisite of all fruits, viz., the Mangosteen. Its creamy rose-tinted pulp and juice are said to possess a bright, delicate, and at the same time rich flavour that is not approached by that of the ripest and finest Nectarine; resembling, as it does, a combination of the Grape and Strawberry, but surpassing both. This rich, creamy pulp is contained in segments similar to those of an Orange; but the rind, or rather husk, is more solid and harder, somewhat similar to that of a Pomegranate. It is a native of the Moluccas, but has been introduced into Java by the Dutch, where it thrives in great luxuriance; and has been sung of by Dutch poets, in ponderous but passionate verse. It has also been introduced to the Malacca coast, where it appears to thrive equally well. I have just been conversing with a gentleman recently returned from Prince of Wales's Island, otherwise Penang, on that coast, who speaks with an enthusiasm akin to ecstasy of its delicious qualities. Dr. Solander, who, as the companion of Sir Joseph Banks, accompanied Captain Cook in his first voyage round the world, speaks of the grateful coolness and exquisite flavour of this fruit; and ascribes his recovery from the last stage of a putrid fever to continually sucking its juice, to allay his burning thirst. It is the only fruit of which, in tropical climates, the sick are allowed to partake without scruple; and its soothing qualities are much valued as a luxury in the sick room, at once delicious and healthful. The tree is of remarkable and handsome growth, with branches issuing at right angles from the main trunk, like those of a Fir, but, instead of Pine-like foliage, having fine shining leaves of an oval form, 7 or 8 inches long. The horizontally-spreading branches are mostly at the top, so that it forms a kind of picturesque umbrella of beautiful foliage, and is so handsome a tree when its flowers, like single Roses, or its fruits, with their rich brown husks, about the size of an Orange, are in perfection, that the Dutch colonists of Batavia look upon it as the most elegant of trees for adorning a garden, and affording an abundant shade. Its name, *Garcinia Mangostana*, embodies that of its first scientific describer, Dr. Garcin, a distinguished eastern traveller, and its native name, Mangostans. It is said that the plant, which was introduced here in 1759, rarely survives its importation to this climate for any length of time; but this must surely be from the nature of its constitution and requirements not being sufficiently understood. It has both bloomed and fruited once in this country—and why not again? In the tropical house at Sion, the late Duke of Northumberland had the gratification of seeing a specimen of this beautiful tree flourish with such healthy luxuriance that it both flowered and ripened its fruit; and the fruit then produced was deemed worthy of being sent to her Majesty for the royal table. Success having been achieved so far, even if the fruit then grown were not produced in full perfection, it has been shown by that partially successful effort that the placing of a fresh Mangosteen upon our English dinner tables is not beyond the range of the present improved state of our horticultural knowledge.

H. N. H.

CLEAN v. DIRTY POTS.

THERE are not a few articles in the gardener's creed which are matters of faith more than experience—maxims that have been handed down to and adopted by us without questioning. In our own time some of these have been confounded, and others totally refuted, by more careful experiment and observation. Among other fallacies of this character is the belief that plants do not thrive so well in a dirty pot as a clean one. By a dirty pot I mean one that a plant has been in before, and which is used again without being washed. I quite expect that this statement will be received with horror as perfect heresy by fastidious gardeners. I repeat, however, that an unwashed pot—in which, of course, there has previously been nothing deleterious to plants—is just as safe and suitable to a plant that has not again to be shifted as one that is perfectly clean; and I make this reservation because I am aware that plants do not turn out well from a dirty pot when they have to be shifted. In other respects, neither a dirty inside, nor a dirty outside, do any harm. In other words, it is a matter of no consequence whether a Pine plant, or a pot Vine, for instance, is finally shifted into a dirty pot or a clean one. I do not wish to dissuade anyone from washing their pots who may be disposed to do so, lest I should be found encouraging untidy habits, and for this reason part of our wet-day work is still pot-washing; but we never wait to wash the inside, at least of our pots for fruiting

Vines, Pines, or other plants, if they are not ready to hand, unless they are so dirty as to interfere with the drainage or the holding capacities of the pot, and then they are only rubbed with a wisp of matting. Another reason is, that we have no time for needless work; and if every pot that we used had to be washed the loss of time would be considerable. Of course I am prepared to furnish a reason for holding this opinion, and I am still open to conviction, if any of your readers can satisfy me that I am wrong theoretically or practically. In the first place, then, one of the chief objections urged against dirty pots is that the dirt chokes up the pores of the earthenware; and this, it is assumed, interferes with the well-being of the roots. It is astonishing how many people still adhere to this belief, simply because they have never given the subject a thought, or at least have never tried any experiments which might lead them to a correct conclusion; and so they go on washing prodigious quantities of pots every year down to the thumb-pots that hold their most indifferent bedding plants, and look upon the work as of paramount importance. It has been shown, however, that the porous theory is not a theory at all, but only an hypothesis, and a wrong one; for plants thrive just as well in pots that are glazed, or made of slate, glass, or any impervious material, as in the most porous earthenware; "experience," as Dr. Lindley says, "has settled this question." As this is the only tangible objection I have ever heard raised, I have no more to answer. What little actual dirt adheres to a pot when a plant is turned out of it becomes part and parcel of the soil with which the pot is filled, and is in no way injurious to the roots; and if anyone tries, they will find a dirty pot just as well filled with roots as a clean one. I have not experimented with all kinds of plants as yet; but I have with pot Vines, Pines, Ferns, and many kind of stove and greenhouse plants; and I might defy anyone to tell the difference between the plants in the dirty pots and those in the clean ones grown side by side. Our fruiting Queens Pines last year were transferred to pots, when shifted finally, from which Pines had just been turned out; they were only wisped, but, notwithstanding this, the fruit was just as good as formerly. In fact, the heaviest Queen we ever grew was cut last year, and weighed within a fraction of 6 lb. All our bedding-stock, except those which go into the additional new pots we get every year, is potted in unwashed pots. Those in the dirty pots thrive quite as well as their neighbours in the new ones; and as the plants are generally rather pot-bound when planted, they turn out of the pots well enough. It will be seen, therefore, that I am not advancing a merely speculative opinion, but facts that I have proved, to my own satisfaction at least. If, therefore, we could only dispense with washing the pots outside on the score of tidiness, we should be relieved of a serious item of annual labour and expense.—"The Gardener."

Tropæolum tricolorum Grown as it Should be.—A few plants of this, nearly 4 feet high and 3 feet through when in flower, always attract attention. When such plants have done blooming they should be removed to a reserve house, where they should be allowed to gradually dry off. When they have completely died down, the pots should be laid for a time on their sides under the stage. In autumn they should be again re-potted, though sometimes they do well without such attention. Loam, with a small proportion of peat and sand, makes a suitable compost for this plant, the bulbs of which should be set about 2 inches under the surface. When the young shoots begin to grow, care should be taken to well cover the base of the trellis with them. The top of a well-furnished Spruce Fir makes a good support for this plant, provided it has been some time cut; a balloon-shaped trellis is, however, generally used.—R. M.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Carnation Blooms in January.—I want Carnation flowers in quantity next January. My plants are strong, just potted into 32-sized pots. Should they be stopped at the points? They are about 7 inches long, and growing in a cold house.—FITZROY.

Propagation of Mesembryanthemum cordifolium variegatum.—I experienced some difficulty in propagating this until I found that it would not stand what is termed "coddling." At first I used to put the pots of cuttings of it in a close frame in the propagating-house; but they so uniformly damped off that I had to try other means; so, on the principle on which other watery-stemmed plants are struck, I set the pots of cuttings full in the sun on a shelf in the same house, and now they strike root as fast as possible.—N. H. P.

Sowing Hardy Primula Seed.—I have recently had an excellent illustration of the uncertain character of the germination of hardy Primula seed. Last year I saved seeds of *Primula cortusoides* *amœna* *lilacina* and sowed them in a pot about the month of August. Of this two seeds only germinated in the autumn, and of these one died before the end of the year. For the sake of the remaining plant I kept the pot all through the winter, and, to my surprise, I found that other seedlings came up about the middle of March; more followed, and now I have some fifty seedlings, all good strong plants, as good as the one that grew in the autumn. I have no doubt that had I kept the seeds until the spring before sowing them they would then have germinated at once.—A. D.

THE KITCHEN GARDEN.

KIDNEY BEANS IN SMALL GARDENS.

THERE is no room for dispute as to the propriety of growing Kidney Beans in small gardens. In the whole of the list of useful vegetables, there is nothing so suitable or so profitable to be found; nothing so easy to manage, nothing that so thoroughly suits all tastes and all occasions. If room could be found for only one vegetable in a garden, the choice should certainly fall upon some kind of Kidney Bean, as affording a maximum of profit with a minimum of risk, and in some cases serving for ornament as well as use. It is well for the owner of a small garden to bear in mind that, although Kidney Beans will grow in any good soil, they grow all the better if the ground is deeply dug and well manured. The truth must be told, that in small gardens Kidney Beans are generally very badly managed. They are put on poor ground, the rows too close together, and the plants too thick in the row; and yet with such bad management they pay—but they pay much better when treated with a little skill. Let the ground be well dug, and unless it is in good heart dig in a liberal dressing of rich manure. For this, as for every other crop, the land ought to be made ready some time before it is wanted, but between what "ought" to be done and what "can" be done there is often a wide difference. The proper soil for the whole tribe of Kidney Beans is a light but substantial loam of considerable depth. In hot, dry, shallow soils the plant may be attacked by red spider, and on cold lumpy clay a wet season will probably kill it. The small gardener can do what the large gardener may find impossible: he can give water to his rows of Kidney Beans, and thus help them amazingly, if the soil is thin and poor, or the summer unusually dry. Kidney Beans are of many kinds. About fifty varieties have been grown here, and there were not half-a-dozen bad ones found. Some are very dwarf and bushy, others show a tendency to run, and will rise 2, 3, or 4 feet high, and others again are true runners, and will rise 6 to 10 feet if in a good soil and properly supported. A considerable number of sorts are quite unfit for a small garden. All the very dwarf and very early kinds that are preferred for forcing are of no use at all to the small gardener. Of the dwarf kinds none are better than Chinese Early, Mohawk, and Negro. These are extremely fruitful and of excellent quality. They provide us with what are termed French Beans. To grow these well they should be sown in drills 2 inches deep and 2½ to 3 feet apart. If there is a want of room and the soil is poor, you may put the rows at 3 feet apart. In our strong soil, 3 feet is the least distance allowable, for the plants spread so that there is only just room left to get amongst them to gather the crop. The great waste of seed in small gardens is a matter to be regretted, for the experience of one season ought to be enough to tell anybody that robust growing sorts, such as have been named above, require to be at least a foot apart in the row, and I have seen them meet at 18 inches. It is a good rule to sow fresh seed 6 inches apart, and afterwards thin to double that distance. But if thin seeding is dreaded, put them singly 4 inches apart, and when fairly up pull out every other one, and with the waste mend any blanks that occur. Having got thus far we have but to keep down weeds, and a plentiful supply of the very best French Beans may be anticipated. In sowing Runner Beans, the same rules should be followed, but a greater distance must be allowed between the rows. Here comes the question, are they to be staked? Now, on that question, I wish to speak decisively. I say that in small gardens they must be staked, and with good strong Hornbeam or Alder stakes, or something as good of home production. The distance between the rows, if they are to be staked, should not be less than 5 feet, and the rows should run north and south, that the sun may shine on every plant with the utmost equality possible. If it is impossible to have rows north and south, more space between must be allowed, and to prevent waste of ground the rows should be 7 feet apart; make a trench for celery between every two rows or put in Winter Greens or sow Lettuces, the main point being to secure for the Runners abundance of light and air. The stakes having been prepared should be driven in rows that must not be too close together, which is often the case, ten times as many plants as there ought to be being crowded into the rows. The best of all the Runner Beans is the old common Scarlet. If no other kind is grown, much will not be lost. The White Dutch is a fine sort, producing plenty of large tender pods; and the Painted Lady, though scarcely first-rate, is admissible for a change, as its flowers are white and scarlet, thus combining the floral characters of the Scarlet and the Dutch. In early districts Kidney Beans may be sown in the middle of April; but, as a rule, it is not safe to sow until the first week of May. One sowing is not enough for any garden. French Beans and Runners are wanted as soon as possible, generally speaking, and a row or two of Chinese Early should be sown as early in April as the average climate of the district will

permit, and sowings of Runners and Negroes should be made in the first or second week of May. Now it is of considerable importance that Kidney Beans should be sown about the middle of June to provide a succession. It is usual for the earliest-sown crops to be quite worn out long before the season is over; but a sowing made from the 10th to the 20th of June will provide supplies of tender Beans until the frost makes an end of all such plants. We have had Runners sown on the 10th of June, close under a fence looking south, bearing abundantly nearly until Christmas, in seasons when the autumnal frosts were brief and gentle. In any case, a row or two sown in the middle of June will pay so well that, whoever adopts the practice once, will continue it. As to gathering the crop, the most profitable way is to gather all, taking the Beans as fast as they acquire a proper size, and not allowing one to become stringy. Even if it is found necessary to give away a quantity, it is best to gather all that can be got as fast as they come; but, if it is considered desirable to save some of the seed, a row, or part of a row cannot be left untouched. If it is gathered from plants that it is proposed to take seed from, the quality of the seed is spoilt. If seed is wanted, trust to plants that have not been gathered from at all; and, as to the rest, gather every pod that can be got.—“Gardeners’ Magazine.”

The Sugar Pea.—I would direct the attention of my fellow-cultivators to the excellent Pea, known in France as the Mangetout, and in Italy as the Wrinkled Pea, in allusion to its corrugated aspect when dried. The peculiarity of the Sugar Pea, as this variety is called in England, is, that the entire pod, if strung like a French Bean, is quite tender and eatable. It is, therefore, much better adapted to the limited space of a cottager’s garden than those varieties, of which more than half must go to the dust heap. The pod, when fit for eating, is of a large size, some times $3\frac{1}{2}$ or 4 inches long, by 1 inch or more wide. It is rather undulating in outline, and flattened, the Peas lying at some distance from one another. It is also very brittle and juicy, showing but little thread at the juncture of the two shells of the pod. When fully ripe, the Pea itself is large, rough, of a full brown colour and rather velvety aspect. In style of growth they resemble somewhat a giant Marrowfat. The Sugar Pea is by no means delicate, and requires no special treatment; it may be sown like the other kinds, from February to the end of July, in rows about 4 feet apart. The space between the rows may be economised by sowing Spinach, Lettuce, Land-cress, Radishes, or any similar low-growing crop. To dress these Sugar Peas for the table, it is only necessary to remove the tip and the stalk of the pod; strings will seldom be found unless the pods have been allowed to get too old. After having been boiled in good soft water, to which a spray of Mint and a little salt has been added, until quite tender, they must be strained to remove water, and served plain, if the eaters belong to the rigid “plain food” school, or mixed with butter and grated cheese, like Asparagus, or better still, stirred in with the Potatoes in making an Irish stew. I have bought the Sugar Pea on several occasions from nurserymen in and about London, but have lately procured it direct from Italy, as, in some instances, I found the English seed too stale to germinate.—I.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Cutting Asparagus: B. D.—The cutting of the heads may be continued up to the last week of June, provided some heads be allowed to grow—say two or three from each crown at the end of May or beginning of June, confining the cutting to those that start from the crown after the two or three shoots to each have been secured.—B.

White Broccoli.—The following varieties of Broccoli are now showing heads as white as the finest Cauliflowers, care being taken to cut them before the protecting leaves open too much to let in the light, or sun’s rays, viz., Dilcock’s Bride, a capital white variety, the Leamington, Watt’s Excelsior, and Cooling’s Matchless—all excellent kinds. Two very late sorts, Carter’s Champion and Cattell’s Eclipse, can likewise be had with white heads, if, as soon as they show that they are coming in, the leaves are tied round them till they are wanted for use.—WILLIAM TILLERY, Welbeck.

Osborn’s Forcing Bean.—I am much pleased to see this Bean so highly spoken of in THE GARDEN, for, so far as my experience goes, it is one of the best with which I am acquainted. We have been gathering for the last three months good crops of these Beans, which are from 3 to 5 inches in length, and of excellent quality. Fulmer’s also has with me proved a good Bean, but in point of cropping not quite so heavy as Osborn’s. I have not grown Canadian Wonder, but have seen it in excellent condition with Mr. Gilbert, at Burghley.—W. M. S.

Hardy Kales.—I find that the Abergeldie variety of the dwarf Curled Scotch Kale is one of the best for withstanding severe frosts. It is likewise a good sort for supplying plenty of sprouts very late in the spring, for at the present time it is with me bearing an abundance of them, and not running to seed so quickly as some of the other varieties do. The Cottager’s Kale, when true, is another capital kind for hardiness, and the sprouts are excellent in flavour when cooked. A very old variety of Kale, the Chou de Milan, is likewise a capital flavoured sort, but it is not so hardy as some of the dwarf Curled Kales.—WILLIAM TILLERY.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

MAY 12.

It was expected that some good Roses in pots would have been shown on this occasion; but, so far as these were concerned, the exhibition was a failure. Beautiful collections of hardy spring-flowering plants were however, furnished by Messrs. Rollisson, Parker, and Dean. From the first of these came fine potfuls of *Gentiana verna* and *G. acaulis*, a fine mass of *Iris iberica*, bearing eleven flowers; also good potfuls of *Iris florentina*, and the snowy *Trillium grandiflorum*, Solomon’s Seal, and *Dicentra spectabilis*. *Primula cortusoides amoena* was also shown in excellent condition. In the same group were likewise dense masses of the snowy *Phlox Nelsoni* and the rosy-flowered *P. setacea*, both well-known hardy species, well adapted for warm sunny borders. Mr. Parker had a well-grown group, in which were effective potfuls of the rich purple-flowered *Iris nudicaulis*, one of the dwarfiest and best of the bearded group; the golden-flowered *Euphorbia pilosa*, a free-growing plant, distinct and effective; *Phlox divaricata*, a slender-habited species, bearing lax trusses of delicate blue or lilac flowers; the spring and double flowered white *Orobis*; and fine masses of *Scilla nutans* and its delicate rosy-flowered variety. Mr. Dean staged a dozen smaller but well-grown plants, among which were one or two of peculiar interest. Of these one was a fresh and healthy mass of the Irish Butterwort (*Pinguicula grandiflora*), a plant with ovate fresh green leaves, slightly glutinous, curling inwards at the edges, and densely set with glandular hairs; its long-spurred flowers, which are nearly an inch in diameter, are of a rich violet-purple with a whitish eye. Apart from its interesting history, as recently set forth by our leading botanists, it well deserves culture as a very ornate-flowering plant. Associated with this Butterwort were well-grown specimens of the lovely blue *Lithospermum prostratum*; a profuse flowering yellow or sulphur-tinted Pansy named Sulphur Queen; the golden variegated Daisy, loaded with rosy-crimson flowers; the rich lemon-yellow flowered *Cheiranthus alpinus*, and the compact-habited snow-white *Iberis corifolia*, one of the best of its class, either for pot-culture or for spring bedding. Some examples of *Aubrietia Eyreii* shown in this collection were unusually striking. It is a plant of dense habit, and one which flowers most profusely, the blossoms individually being nearly three-quarters of an inch in diameter, and of good substance. In the class for cut flowers of herbaceous plants Mr. Parker had some fine clusters of the golden-flowered *Trollius napellifolius*, *Iberis Garreuxiana*, *Centaurea montana alba*, purple *Iris*, *Tulipa gesneriana* (with rich crimson flowers), *Spiraea japonica*, the Golden *Alyssum saxatile*, and the ever-welcome *Aponogeton distachyon*. Mr. Dean also had an effective group, in which were Lily of the Valley, the orange-flowered *Cheiranthus Marshallii*, *Polyanthus Red Rover* (purplish-crimson with a golden eye), *Myosotis dissitiflora*, purple German *Iris*, double white *Saxifrage*, golden-flowered *Madwort*, and *Arabis rosea*. Some Alpine *Auriculas* were likewise staged by the same exhibitor, and also by Messrs. Dobson of Isleworth. Mr. Dean had an effective group of double Daisies, among which were white, rose, crimson, and golden variegated forms.

Azaleas.—Half-a-dozen well-grown Azaleas came from Mr. Herrington. They consisted of conically-trained plants of Flag of Truce, one of the best of all double-white kinds; Stella, a well-known crimson-scarlet sort, shot with purple; Duc de Nassau, a large-flowered semi-double variety of a bright rosy-lilac colour; Iveryana, pure white; Sir Charles Napier, rosy salmon; and Criterion, a delicate-tinted rosy variety, spotted with crimson and variegated with white. Mr. Coles had also a well-grown group, in which were Trotteriana, rosy-lilac; Iveryana, Holfordi, a fine semi-double form, having bright rosy-crimson flowers; and Eulalie Van Geert, a delicate salmon, spotted with deep rose and margined with white. Messrs. Dobson had Criterion, rosy-salmon, margined with white; Reine des Doubles, a profuse-flowering semi-double rosy-lilac; Sir C. Napier; and Duchesse Adelaide de Nassau, an effective variety in the way of Stella.

Miscellaneous Subjects.—Fine specimens of Tree Mignonette came from Mr. Coulter, who furnished conical-shaped plants, fully 3 feet in height, and nearly as much in diameter at the base. Mr. Barnes had half-a-dozen smaller plants of the white-flowered variety. Messrs. Dobson staged nine named seedling Calceolarias, among which were Canary, a brilliant yellow; Achievement, yellow spotted, with crimson-brown; Hamlet, rich velvety crimson; and Enchantress, lilac-purple. Mr. Clarke also had a well-flowered collection. Of Roses, Mr. Herrington showed six plants in pots; and the same exhibitor was awarded a first prize for twelve cut blooms. Mr. W. Paul, who likewise staged six stands of cut Roses, exhibited his new Hybrid Perpetual, called Star of Waltham, in excellent condition. Messrs. Carter & Co. showed a basket of variegated Musk, and their new Coleus, Duchess of Edinburgh; also well-grown specimens of their Pyramidal Bouquet Mignonette. Mr. Pounce exhibited a robust-looking seedling form of *Lomaria gibba* under the name of L. Pouaeii. *Cypripedium japonicum* was furnished by the Colchester Bulb Company. It is a rare and little known plant, figured by Blume, and also more recently in the “Flore des Serres,” but never flowered in this country until this year. A seedling double Pelargonium from Mr. Woodward was thought by the Floral Committee to be a double form of *P. cucullatum*. Of Mimuluses, Mr. Dean sent cut flowers, which varied in colour from creamy-white to golden-yellow, richly blotched with maroon or crimson. Mr. Gray showed a vigorous plant of the crimson-flowered *Masdevallia amabilis*, bearing fourteen flowers. A new dwarf white-flowered Pelargonium, named Duchess of Edinburgh, came from Mr. G. Braid, Winchmore Hill. It is dwarf in habit,

and a most profuse bloomer, Mr. Laing of Stanstead Park exhibited *Caladium Madame de la Derausage*, a kind with broadly hastate foliage, creamy-white in colour, with green margins and rosy-salmon veins; *Bertolonia Van Houttei*, as shown by M. Van Houtte, has deep-green leaves, dotted and veined with rosy-carmine. A new erect-flowered *Gloxinia*, named Duke of Connaught, came from Messrs. Carter; it has flowers of rich velvety crimson inside, and pale rose outside. A small plant of *Pinguicula grandiflora* came from Messrs. Veitch; also two flowering plants of *Iris florentina*, having glaucous foliage and milk-white flowers; Mr. B. S. Williams furnished a crimson-flowered *Azalea*, named Flambeau, which obtained a second-class certificate; also *Adiantum gracillimum*. A dwarf, yet vigorous-habited, *Mignonette* came from Mr. Miles, of Brighton; it is very fragrant, and is said to be a cross between Parson's tree *Mignonette* and the old dwarf variety. A ripe fruit of *Stephanotis floribunda* came from Mr. Welsh.

Fruit and Vegetables.—Mr. Batters sent a small collection of vegetables including Peas, French Beans, Custard and common Marrows, Cucumbers, Tomatoes, and some good early Potatoes. Mr. J. Barclay had specimens of *Morchella crassipes*, or Morell, a sponge-like Fungus used by some in cookery. Mr. Sidney Ford contributed eight dishes of Apples, in excellent condition, the varieties being London Pippin, Red Pearmain, Scarlet Nonpareil, Ashridge's Pine-apple Pippin, French Crab, and Wellington. Mr. F. Dancer sent an excellent dish of well-grown Asparagus; as did also Mr. W. Allen.

First-class Certificates.—These were awarded to the following new or rare plants:

Rose, Star of Waltham (Paul).—One of the best new Roses of the year, and one which has been certificated by the Royal Botanic Society. It is a full Rose, of good substance, and bright rosy-carmine in colour, tinted with lilac. It is a free grower, and flowers profusely.

Bertolonia Van Houttei (Van Houtte).—A beautiful stove foliage plant, with ovate velvety-green leaves, dotted and veined with bright rosy-carmine.

NOTES AND QUESTIONS—VARIOUS.

Abutilon Darwinii.—This plant has proved to be hardy as tried at Glasnevin during the past winter.—W. E. G.

Pink Grape Hyacinth.—Has anyone ever seen this? Twice I have imported from Holland bulbs professing to be of a rose-coloured Grape Hyacinth, and on each occasion they have produced pure white flowers.—SALMONICEPS.

Chicory in Coffee.—The essence of Chicory, for use as a substitute or addition to coffee, is now a product of German industry and economy. If our coffee dealers would only give us the choice of coffee pure or this essence it would be well.—W.

An Inexpensive Table Decoration.—A good stubby and well-coloured plant of *Panicum variegatum*, and a few select Tulip buds make a useful combination for this purpose. The brilliant colours of the Tulips associate well with the graceful white striped Grass.—R. M.

Keeping Mice off Peas.—It may be useful to those who are now planting Peas to know that the most efficacious plan of keeping them from mice is soaking them in bitters—say bitter Aloes or Gentian. They do not affect the taste of the Peas, or in any way injure their growth.—R. M.

Standen's Manure for Pot Plants.—A large plant of *Heliotrope*, 5 or 6 feet across, was induced to flower satisfactorily at mid-winter, through being top-dressed with Standen's manure. Some large *Mignonette* plants, 3 feet through, also dressed with it, although looking yellow, and sickly before its use, soon grew away with renewed vigour.—R. M., *Abney Hall, Cheadle*.

Phlox verna as a Bedding Plant.—This pretty old-fashioned Phlox is now in use at Kew as a spring bedding plant; and, employed in combination with the pale pink *Phlox frondosa*, *Aubrietia græca*, double white Daisies, *Ajuga reptans*, and Golden Feather *Pyrethrum* it is most effective, its rich rosy-red colour being rare amongst spring-flowering plants.—A. D.

Inarching Zonal Pelargoniums.—W. E. E.—It is not necessary to use clay; merely tie with matting, and then cover with moist Moss. In about six weeks the union will be complete. Leave a joint or two above the junction on the stock; but all the shoots operated on should be shortened and kept from growing much, so that the sap may be diverted into the scions. The part above the scions will, as soon as the union is complete, need to be cut off closely.—P.

Mistletoe best Raised from Seeds in Spring.—About three weeks ago I bruised some Mistletoe berries on the branches of several Apple trees in the orchard, and to-day (4th May) I observe that the seeds have begun to germinate. I have tried them several times before by sowing the berries at Christmas and inserting the seeds in the bark of Thorn and Apple trees, but without success. It may be best to put them on in April, as in this case, and to simply squeeze the berry on the outer bark. Nearly every berry put on has commenced to grow.—R. M.

Dutch Hoes Adapted to Various Sizes of Blades.—Usually, when looking over one's tool-house, one is perplexed by the large number of tools which gardening seems to require. Of Dutch hoes, for instance, there are one or two with 4-inch blades, one or two with 6-inch blades, and one or two with 9 and 10-inch blades. Now I have found out how to make one shaft and prong do for all these sizes of blades. Let your blacksmith chop off your present blades (that is, if they are getting worn out; it would be foolish to meddle with them needlessly), and draw the prongs in to 4 inches across their ends. Then have sockets made at the ends into which the blade must be put; and the best blades I have found are those made from old worn-out scythes; they are always cheap, and they wear well.—N. H. P.

Hale's "Eden."—I am much obliged to Mr. James Britten (see p. 373), for pointing out that this work is by J. Hill; but it is catalogued at the British Museum as being the work of Thomas Hale, and the name Hale is also on the back of the volume. London says the work is by Hill, which I do not doubt. Nearly all the drawings in this interesting book are by Hill, and some of them he appears to have engraved himself. Some time ago I noted some interesting papers on old English gardening books in the "Bookseller," and I should like to procure these, if they are still to be had. In speaking of the preface to John Parkinson's "Paradisus," the author says it is "engraved on copper by Switzer;"

but on looking at my copy of the second edition (1656) the other day, I observe that it is an engraving on wood, as are all the other illustrations in that fine old book.—B.

Arabis blepharophylla superba on Rock-work.—This lovely little Alpine is now in flower on the rock-work at Kew. It has a close habit of growth, and the blooms, which are pale rosy-red and borne in neat trusses, are elevated about 5 inches from the ground. Amongst spring flowers it is quite a gem.—D.

The Peruvian Daffodil (Ismene Amœnaes).—Of this, the New Plant and Bulb Co., Colchester, say, "This, until re-introduced by us last season, and again this, was quite lost sight of." This is not correct; it has appeared for many years in Messrs. Ant. Roozen & Son's English Bulb List, and I could mention at least a dozen nurserymen who offer it, and have done so for years.—Rex.

The Edible-rooted Everlasting Pea.—The tuberous-rooted *Lathyrus* is recommended by some of the Continental journals as a substitute for the Potato. Formerly the roots were in some demand, as, when boiled or baked, they are both sweet and nutritious, but they can only be regarded as a makeshift, not as a substitute for the Potato. The plant itself is a handsome perennial, bearing purple-red flowers, which are sweet-scented.

White Swede Turnip.—I have just tasted a dish of improved white Swede Turnip, and find it to be of excellent quality. It will, no doubt, be of great use in gardens where a late supply of Turnips is required. I would strongly recommend it for such purposes; and those who have an objection to the yellow Swede on account of its colour, will find this as fine in colour as the white Stone Turnip. Messrs. Stuart & Mein state that it is beginning to be a favourite on account of its good keeping quality.—CHEVALIER.

Apple Prospects in Devon.—Orchards in Devon are now coming well into bloom, and there is every prospect of good crops. It is a common saying here that "April blossoms are no good," and that "we never knew a bearing three years in succession." This year will, however, I think, be an exception. During the last two years the crops were very heavy, and judging by the amount of blossom and healthiness of the trees in good land, we may expect an abundant crop.—J. GARLAND, *Killerton*.

Exterminating Bindweed. L. S. T.—The common means of destroying Bindweed is to fork it out, taking away every portion of the roots. This, however, cannot always well be practised, but whenever the ground is not under crop it is well to use the fork if the roots are deep. A certain remedy is persistent and regular destruction of the tops. If these are never allowed to push above the ground for more than a week without being destroyed, the roots soon perish.—B.

Rose Insects.—What is the name and best means of destroying the insect sent herewith? Several young Roses against the wall of my house have been nearly destroyed by it.—E. W. R., *Mayfield*. [*Otiorynchus notatus* is its name, and most probably there are Fir trees near the Roses, for it chiefly breeds upon them. It is not so easy to suggest a remedy. Would "E. W. R." mention in what way it attacks the Roses; if by eating the leaf, would he send specimens of the injured leaves?—A. M.]

Naming Newly-imported Lilies.—Permit me to state, in answer to Mr. Bull's note (p. 377), that "*L. Washingtonianum* new species" is Messrs. Backhouse's name, not mine. My object in writing is to prevent any but provisional names being given to newly-introduced Lilies until we know more about them than we do about *L. Washingtonianum*. Of this Lily we appear to have about three varieties, that is supposing that Messrs. Backhouse's *L. Washingtonianum* new species proves distinct from Mr. Bull's *L. purpureum*.—GEORGE F. WILSON, *Heatherbank, Weybridge*.

Vines Killed with Oil (see p. 396).—I have long since noticed, on the leaves of various hothouse plants, the effects of oil which was applied merely to show its power, the result being that the leaves were discoloured and fell off. A striking illustration came under my observation a few weeks ago, when a gardener was induced to attempt the destruction of a mealy bug upon his Vines by means of oil. Having pruned and dressed them, the oil was applied, and he has destroyed his Vines if not the bug. In one house the Vines have all turned black and are dried up, which plainly showed that there was no transpiration whatever.—WILLIAM LAURIE.

Brodiaea californica.—This plant, referred to in your last issue, is, properly, the *Brodiaea volubilis* of Baker, first introduced by me to this country, and it is, I think, greatly to be regretted that a synonymous name should be put forward. The statement that it continues to bloom and seed through the summer, after being taken from the ground, is, I apprehend, scarcely correct. This notion is due to the fact that the perianth retains its colour when dried, as may be seen in herbarium specimens. In cultivation the bulbs do not descend to any depth. The plant is very easily grown in any light soil.—W. THOMPSON, *Ipswich*.

Plum-coloured Wood Lily (Trillium atro-purpureum).—This well deserves a place in the hardy garden, where it forms a worthy companion to the white American Wood Lily (*T. grandiflorum*). It is, however, quite distinct from it in colour and form of flower. The three petals are a rich plum colour, spread flat out, with three intervening petal-like sepals of a pale green, tinged with purple, the whole being slightly recurved, and nearly 3 inches in diameter. Planted side by side with its white companion in a little artificial bed of sandy-peat, in shade and shelter, it shows itself above ground and blooms a fortnight earlier than *T. grandiflorum*.—G. F.

Forcing French Beans.—Mr. Temple surely must have glass by the acre to be able to possess 300 pots of French Beans at one time, unless he grows them in 60-sized pots. Here I find forty pots in use at one time to be quite sufficient, and only a week back I met my foreman coming out of one of the Vineries with a peck of French Beans. I am, however, afraid that the seed trade are rather mystified with regard to Canadian Wonder, for what I received for this, last year, turns out to be Red Flageolet, which is larger in the pod than Canadian Wonder. The former I grow in 16-sized pots, three plants in each, and they are so thoroughly satisfactory that I grow no other.—R. GILBERT.

Hathaway's Excelsior Tomato.—John B. Davis, of King William county, Virginia, proprietor of an establishment for preserving fruits and vegetables, wrote to Mr. James Vick last autumn the following note concerning this favourite Tomato:—"Having bought of you four pounds of Hathaway's Excelsior Tomato seed, the fruit from which we are now preserving, they have proved to be what you represented—the very best Tomato this day known for canning and general purposes. They are a wonder to every one who has used or seen them, being round, smooth, of a beautiful dark red, very solid, and cutting equal to a beef-steak. I could fill half-a-dozen sheets of paper on the merits of this Tomato, and would then feel as though I had only half spoken its praise."

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

BUDDING ROSES IN MAY.

I BUD all my new Roses early in May, and generally get about two dozen plants of them about the last week in April, all of which are in pots, and have one or more long shoots each. They are placed temporarily under a south wall, and the pots are plunged up to their rims in the soil. Here, after exposure to the air, the wood hardens a little, and, by pinching off the top of each shoot, the buds soon become sufficiently developed to be removed and inserted into Briars. I usually commence budding on the 5th of May; this year the operation was delayed to the 8th, the season being backward. The Briars which I bud are not those that were planted last November, but those which failed last summer. These, after cutting away last year's growth, on account of having good roots, began to grow much earlier than such as are newly planted, and on the 8th of May had made shoots 9 inches long, and, being full of sap, were in good condition for budding. I cut down a shoot from one of my new Roses, leaving the four lowermost buds, so that when the plant is turned out of the pot and planted out three eyes or so are left, from which good shoots are produced which bloom in the autumn. Owing to the young shoots on the Briar being very tender, May budding is a very delicate operation, and one which requires both care and judgment; and a sharp knife is indispensable. First make an incision about three-quarters of an inch in length, and not too deep; then open up the bark with a piece of ivory, or hard wood, like a pointed common black lead pencil, cut flat and thin. Now cut the bud, which need not be longer than half an inch; cut it very thin, and do not attempt to remove the wood; insert it by pushing in one side first, then take the pointed piece of ivory or wood, and work in the other side; then tie up, as usual, with cotton, worsted, or bast. I never make a cross cut, which weakens the branch so much that the weight of the future growth is almost certain to break it at the cross-cut, which may, however, be used with safety in the case of autumn budding when the wood is nearly ripe. Proceed in this way until every bud that can be taken from the shoot of your new Rose, even up to the very tip, is inserted, and the result will be that a great number of Briars will be found to have been budded with new Roses, all of which are certain to take and become firmly united. The following year new Roses will be produced by the bud, and these first Roses are said to be the best. Formerly people, when planting out their new Roses from pots, used to cut down the long straggling shoots and throw them away; but by my plan every bud is made into a standard Rose, and one soon becomes possessed of a large number of trees of the new and improved varieties. Briars planted last winter are now pushing actively into growth; but they must not be budded until the shoots are at least 6 inches long. After ten years' practice, I can bud a Briar shoot when it is only 4 inches long; but this should not be attempted by beginners. When budding is performed on shoots only 4 inches long, they often begin to curl and become distorted just above the bud, and this is a sign that the bandage around it wants easing a little. July and early in August are the next best times for budding, and the buds for use in these months are best taken from a shoot which has just done flowering. Rosarians have cause to rejoice this year at the large number of really good new Roses that are being sent out, more especially Tea-scented varieties, which are said to be unusually good. From such new Roses as have come under my own observation the following is a good selection:

Best Tea-scented of 1875.—Aline Sisley (Guillot), purplish-rose, shaded with violet (obtained a gold medal at Lyons); Jean Ducher (Ducher), yellow, shaded with salmon, very fine; Duchess of Edinburgh (Veitch), rich deep glowing velvety-crimson, a free bloomer and highly fragrant, an acquisition as regards colour; Marie Guillot (Guillot), white, tinged with

yellow, large and full form, imbricated (obtained a gold medal at Lyons); Marie Opoix, white, yellowish in the centre, much better than Niphetos, a good exhibition flower; Comte de Sembui (Ducher), salmon-rose, large and full (first prize last year at Lyons); Perle des Jardins (Levet), colour varying from pale yellow to deep canary-yellow—of the highest merit, large, full, and well formed; on account of its rich colour and continuous manner of blooming, a formidable rival to Maréchal Niel (obtained a medal last year at Lyons). Shirley Hibberd (Levet), Nankin-yellow, distinct and vigorous, a large and full-cupped Rose, to which a first-class certificate was awarded at Lyons in 1873.

Best Hybrid Perpetuals of 1875.—Hippolyte Jamain (Lacharme), carmine-rose, very large and full, an acquisition; Gonsoli Gaelano (Pernet), delicate satiny white, in the way of Souvenir de Malmaison, and very beautiful; Villaret de Joyeuse (Damaizin), large and very full, fine in form, colour delicately shaded rose-pink, a good exhibition Rose; May Turner (E. Verdier), a first-class Rose in the way of Caroline de Sansal, very large and full, fine in form and vigorous, colour salmon-rose, deeper in the centre; Colonel de Sansal (H. Jamain), carmine, shaded crimson, fine in form, large and full, a splendid vigorous-growing Rose; Comtesse de Serenyi (Lacharme), like la Baronne de Rothschild, large and full, and fine in form, colour delicate shaded rose; Antoine Moutin (Levet), bright rose with a silvery reflex, and almost as large as Paul Neron, to which it bears some resemblance; Souvenir de Mère Fontaine, large, full, and well formed, colour bright rose, with carmine centre, vigorous and good; Souvenir du Baron de Semur (Lacharme), blooms large in size, fine in form, and very full, habit vigorous, colour deep velvety-purple, shaded with black and deep fiery-red; Madame Rivière (E. Verdier), a useful variety for exhibition purposes, colour beautiful rose, very delicate and fresh; not exactly a Hybrid Perpetual, though I have placed it under this head. Among other Roses coming out this spring doubtless many upon trial will turn out good. Some of the new varieties do not show themselves in true character for several years; hence we must not condemn any too hastily, but go on patiently cultivating them, until they are proved to be worthless.

HENRY TAYLOR.

Fencote, Bedale.

LONDON SQUARES AND PARKS IN MAY.

THERE is a period of the year when, even in the heart of London, the spring foliage is beautiful—more attractive, if possible, than in the country. The contrast which the fresh leafage, and the first gush of bloom of the Lilacs and Laburnums bring to the hard and regular lines of the terraces of Tyburnia, Belgravia, and "Kensingtonia," is a most charming one—and the unusually late advent of the present splendid spring weather has been the means of keeping back the progress of vegetation, till the east winds had done their worst on naked branches and over-precocious blossoms—so that the young foliage, which has at last burst forth under the influence of a sudden rise of temperature, has not been nipped by cold nights, and remains beautifully perfect and uninjured, as it generally does in exceptionally late springs. Another advantage derived from the lateness of the present season is, that the Lilacs, Laburnums, Guelder Roses, Hawthorns, and other shrubs, which generally follow each other, are now all out in a glorious display of bloom together. In ordinary seasons the Lilacs are, as a rule, over before the Laburnums are fairly out, and they, in their turn, have nearly passed away before the white and pink Hawthorns begin to perfume the air. In consequence of the unusual advantages alluded to, Hyde Park and Kensington Gardens are just now really lovely. Entering the park by the small gate in the Bayswater Road, the diverging drives, bordered by their plantations of Lilacs, Laburnums, and Horse Chestnuts in full bloom, present a strikingly agreeable aspect. All is fresh and beautiful in the extreme, and even the sooty branches, dyed with their true London black, form a contrast with the bright and tender green of the young leaves that is very beautiful. Passing on towards the bridge, the venerable wrecks of the aged Spanish Chest-

nuts, with their symmetrically-striated and deeply-ridged bark, never fail to attract attention. It seems strange that, among the numerous young trees that are being judiciously planted, more Spanish Chestnuts, to succeed the old ones, still so beautiful in their picturesque ruins, should not be found among the number; as it is evident, from the vigorous character of the young foliage that now clothes portions of the fine old trunks, that the Spanish Chestnut is capable of defying the worst attempts of London smoke. At the stone summer-house, generally known as the Lodge, the present display of floral colour consists entirely of Tulips, and the effect is as homogeneous and pleasing as it is dazzlingly vivid; scarlet of several tones, orange, yellow, white, pink, and mauve afford a wonderful opportunity for producing striking contrasts of brilliant colour within the range of a single genus. Passing on to the "flower walk," we find the borders somewhat bare. The Hawthorns, however, in the shrubberies at the back of the border are so lovely and so sweet, double, single, red and white, that the absence of the border flowers is almost condoned by their beauty. The effect of the shrubberies, pleasant as it is, might, however, be improved and enriched by adding here and there standard plants of *Cydonia japonica*, both scarlet and flesh-coloured, and also by introducing standard Wistarias, both lavender and white. When we say standard Wistarias, we mean, of course, supported by low stakes. And why have we not splendid bushes of Clematis, also, at short distances all along the flower walk. When one sees the display which these are now making in the Regent's Park, and knows that all those magnificent flowers—of every conceivable shade of mauve, purple, white, and blush,—now being exhibited there, are perfectly hardy, it seems quite incredible that little or no use is made of their beauty to improve the floral decoration of our favourite public promenades. It may be urged that in the open ground the Clematis family would not be in full bloom at present; but, under ordinary circumstances, there would scarcely be more than about a fortnight's difference between the time of their flowering in the open air and under the protection of glass. In the Botanic Gardens, Regent's Park, the beautifully laid-out grounds are now at their best, the Horse Chestnuts being, both there and in Hyde Park, in more than usual beauty this season. This magnificent tree might well be called the Hyacinth tree, and would do more ample justice to the name than does the Tulip tree, or the Paulownia, which is sometimes named the Foxglove tree. Many other kinds of well-selected flowering trees are now in full bloom in the Botanic Gardens, and shady borders are still gay with Polyanthus, Primroses, Cowslips, and Squills. The great avenue in Regent's Park now forms a magnificent promenade, and the symmetrical gardens on the eastern side of the avenue are this year a decided success. They have been improving year by year for some time past, and their trees and shrubs have now attained to about the most attractive stage of their growth. The outlying parks of the eastern and northern suburbs are also displaying the advantages of the lateness of the season, as their young foliage is entirely unlighted by the action of those cold cutting east winds, which are but too frequently so fatal to the beauty of our early foliage and blossoms. From the same cause the foliage in the larger squares, such as Lincoln's Inn, Russell, and others, is unusually fine this season, and the trees in the terraces and villa gardens of the west and south-west are now in great beauty—white and red Hawthorns, Lilacs, and other favourite shrubs, being in profuse and healthy bloom, even in comparatively closely-built districts. A mass of Persian Lilac in Sloane Square, with very pale blush-toned flowers, is very noticeable; and, whether its flowers have assumed their delicate tone by the absence of the ordinary amount of sunlight in that situation, or whether the bush in question is an accidental variety matters little—the effect is charming. Just now, in fact, all London is, in regard to its foliage, at its very best; and, if painted, should be seen in the May of a late spring, when its Wistarias and purple Iris, which seem positively to enjoy its smoke, when they do not get too much of it, are in their prime. This season the foliage of the Wistarias is out at the same time as the flowers, which greatly enhances their beauty.

H. N. H.

NOTES OF THE WEEK.

— MESSRS. JOHN WATERER'S exhibition of Rhododendrons is, we hear, to be held in Alexandra Park this year. A spacious tent has been erected for their accommodation at the east end of the palace, and from what we know of these exhibitions a brilliant display may be expected.

— WE have received a most interesting cluster of late-flowering Bluebells or Scillas, of the *S. nutans* and *S. cernua* types, from Mr. P. Barr. These Scillas are invaluable for the decoration of the margins of woodland walks, or for that of ordinary herbaceous borders. We saw some splendid tufts the other day in the kitchen gardens at Belvoir, where they form most attractive objects in the borders. Mr. Barr is doing good service in gathering together these pretty Bluebells.

— THE old rosy-flowered Chinese tree Peony is just now a very attractive object in good gardens, its great Rose-like flowers being deliciously perfumed. We saw a specimen 5 or 6 feet in height, and quite as much in diameter, at Belvoir, the other day, profusely covered with large fragrant flowers. Tree Peonies have been introduced to our gardens since 1789. As pot plants, some of the new varieties are invaluable.

— THE meeting of the Scientific, Fruit, and Floral Committees of the Royal Horticultural Society, fixed for the 26th instant, has been postponed on account of that day being Derby day. The next meeting of these Committees will take place on Wednesday, June 2nd.

— THE Pomological Society of France have decided to invite a competition in the invention of a practical and efficacious method of destroying the American blight. A gold medal will be given to the discoverer of the best and easiest remedy, and the competition is to remain open for three years.

— A SPECIAL general meeting of the Royal Horticultural Society will be held in the Council Room, South Kensington, on Tuesday, the 25th instant, at three o'clock, p.m., for the purpose of receiving a communication from the council respecting the future prospects and condition of the society, and to receive an answer to proposals made by the council to her Majesty's commissioners.

— MESSRS. SMITH'S nursery, at Dulwich, is just now worth a visit, the new Azaleas being in excellent condition. Messrs. Smith have made themselves a name for Balsams, Calceolarias, and Cinerarias, and we recently saw some thousands of each of these favourite decorative plants being grown for seed-bearing purposes. Only 1½ to 2 lbs. of Cineraria seed is saved annually from the thousands of seed plants grown, but this seed is easily sold to the trade at from £5 to £6 per ounce. Double white Camellias are also grown here by the thousand for the nursery trade.

— THE fine old gardens at Hampton Court are just now very attractive, and the matchless avenues of Chestnuts in Bushy Park at their best. In the gardens we noted several clumps of great rosy-flowered tree Peonies in full flower, and these exhale a most delicate rose-like odour. The fragrant Wistaria *sinensis* drapes walls and trellises with a rich profusion of its delicate mauve Pea-shaped flowers. The front of the gardener's lodge, near the famous Vinery, is entirely covered with a splendid specimen of this most elegant of all Chinese hardy climbers; and a pure white-flowered variety is growing and flowering well on the old Orangery. Some of the buttresses of the last-named structure are draped with the snowy Clematis *montana*, and we also noted it in other parts of the garden flowering most profusely. This Clematis, and the white-flowered Wistaria ought to have a place in every garden.

— "FOOD PLANTS of the Larvæ of the British Lepidoptera," by Owen Wilson, Barrister-at-Law, is the title of a new work that will shortly be published on this subject, in twenty monthly parts, illustrated by forty beautifully coloured illustrations from Nature. The first portion of the work will contain a list of caterpillars according to Mr. Doubleday's arrangement, with their scientific and English names, their form, colour, and description, the time they feed, and the plants they eat, and, when necessary, the localities in which they may be obtained; also the time and situation in which the chrysalis is found, and the month in which the perfect insect flies. There will be an alphabetical list of plants, with their English and botanical names, and the names of the caterpillars which feed upon them. Following this will be a calendar of the months in which the caterpillar may be found, another showing when it is in the pupa state, and a third giving the time when the butterfly or moth appears on the wing. The work is intended to enable the entomologist (and also the amateur) to detect at once the perfect insect upon finding the caterpillar and its food plant. Should the naturalist obtain the caterpillar without a clue to its food plant, the calendar of months, and the descriptions together, will, it is hoped, enable him to find it

THE FLOWER GARDEN.

CARNATION CULTURE.

IN order to have this beautiful flower in perfection, the principal thing to be done is to obtain soil in which it cannot fail to flourish, for it is an ascertained fact that there is no natural soil in this country that answers all the requirements of the plant. Yet, unless such be in some way provided, the time, labour, and money of the cultivator are alike thrown away. The first thing to be secured is some good loam, which should be obtained from maiden ground, the top spit only being useful. The loam must not be so strong or clayey as to adhere to the fingers when crushed; but must feel soft and oily. The following, which is the compost used by an old grower of Carnations and Picotees, will, with proper attention, secure success. Take two barrowfuls of maiden loam, one barrowful of good black soil, two barrowfuls of thoroughly-rotted horse-dung from an old Cucumber bed, and about half a barrowful of coarse clean water-sand, or any sand that has been thoroughly washed with water. If the loam happens to be of a somewhat stiff nature, the quantity of sand must be increased. These ingredients will form a suitable compost, and the heap must be kept a year at the least, and frequently turned, especially in winter during frost, in order to get it thoroughly mixed. Whilst this is being effected, a little hot lime should be thrown in, which will be found of great service in killing insects, which are very destructive in eating the tender roots of choice varieties. A little lime has also an excellent effect on the soil, which is much sweetened by its application. The method of propagation is by pipings, or by layers, and the best time for taking these is when the plant has come into bloom, and before it is too far advanced, otherwise they will have become hard, and are apt not to strike so easily. A quantity of sand deposited round the base of the plant greatly assists the layers to root. In order to raise double flowers of Carnations and Picotees the best seed only should be procured. Go only to the most respectable dealers, where, though you may, perhaps, pay a high price, you will at least obtain what you want. When you get good seed do your best to save it yourself; the best varieties do not yield much seed, hence it is rather dear. April and May are the best months in which to sow the seed, which must be done either in small beds made up for the purpose or in large pots; the seed must be lightly covered with fine compost. When the plants are large enough, which will probably be the case the following February or March, they must be planted out in a bed prepared with the compost

before described; the distance between the plants should be 10 inches. Before the flower-stem makes its appearance the pots, if the plants are in them, should have a top-dressing of good compost, water being given during the growth of the stem and the swelling of the flower-pod. As the plants advance care must be taken that the pods have no tendency to burst on one side; this may be prevented by gently tying with a shred of bast, or, if it is obstinate, the opposite side of the pod may be slit with a sharp knife. About this time the

side shoots should be taken off and the bloom-pods in the truss reduced to the number which the stem can properly bear. After the growth has advanced a little further, circular pieces of card should be put round immediately under the flower, and the guard or lowest series of petals spread neatly upon them; then paper caps or small shades of glass must be suspended over the flowers in order to prevent the sun and rain from injuring the colours, and should be removed towards evening to give a little air. If these precautions are taken the blooms may be obtained in the greatest possible perfection. If the plants are to be bloomed in pots the latter should be very large, and the plants transferred to them in March or early in April, after which the treatment is the same as for those in borders or in beds. In winter the plants should be secured from very severe weather by hoops and mats, or similar means, but they should still have as much of the free air as possible on all favourable occasions. Carnations require free exposure to pure air, except at times when this would affect the colours of the blooms, and then the latter must be protected by shades of glass or paper as before described, but the Grass must be left as freely exposed to the air as possible. Carnations are usually divided into three classes—Flakes, Bizarres, and Picotees. The Flakes have the colours in broad stripes, seldom more than two in number—white being the ground colour, and the second colour any shade from deep purple to the palest pink of the Peach blossom. The colours of Bizarres are usually broken into stripes; and this kind is dependant for its beauty on the proportion of the various tints, and the manner in which they are contrasted. Carnations are

Armeria mauritanica (see p. 421).

best known as scarlet Bizarres, crimson Bizarres, pink and purple Bizarres; scarlet Flakes, rose Flakes, purple Flakes, and pink Flakes. Picotees are differently marked, being dotted or marked over with little spots, and their colours being in greater breadth. A good deal of their beauty depends upon the tint and brilliancy of these dottings. There are purple-edged, red-edged, rose-edged, and scarlet-edged; these are on a white ground generally, but many very beautiful varieties can now be procured having a yellow ground. There

are also many beautiful varieties of the scarlet Picotee, such as Attraction, Fellows's Attraction, and Miss Osborne. It is very difficult to say which of the Picotees is to be preferred, for there are many varieties, all of which are exceedingly beautiful. In addition to colour, the flower should be of ample size, the petals finely formed and arranged, and the Grass or stem supporting the single flower or truss should be strong, and of a healthy colour. These conditions can only be secured by growing the plants in a suitable compost. Good Carnations and Picotees can now be bought at very reasonable prices—indeed, almost as cheap as common scarlet bedding Geraniums. I often grieve to see good varieties grown as they are in most of our gardens in front of villa residences. Many appear to have an idea that if they make a hole in the soil, and put in the plant from its pot, that it will grow into a fine specimen. It cannot be expected that persons unacquainted with the culture of the Carnation can be expected to bring it to such a state of perfection as an experienced cultivator, who makes it the peculiar object of his care and study, can; yet much may be done by the amateur, if the advice I have given respecting compost be followed. At the proper season of planting, which is March or about the first week in April, dig a hole in the border or bed where the plant is intended to bloom, fill in two good spadefuls of the compost, and then insert the plant, giving a good watering to settle it in the soil. The plant will flourish much better this way than if planted after the manner formerly adopted, which consisted in scratching a hole in the border about 3 inches deep with the fingers, inserting the favourite plant, and then pressing down the soil, by which procedure the roots are broken.

HENRY TAYLOR.

Fencote, near Bedale.

THE LILIES.

By C. M. HOVEY, Ex-President of the Massachusetts Horticultural Society.

THE readers of THE GARDEN must feel deeply indebted to you for the re-production of Mr. Baker's exhaustive paper on all the Lilies, beautifully illustrated as it is by you. It straightens out and makes plain much of the confusion which has existed in books, and especially catalogues, of these most beautiful plants; and a careful study of the paper and illustrations, and an equally careful examination of the plants by intelligent cultivators will soon weed out the synonyms and establish a true nomenclature. I have often been surprised at the apathy which exists in regard to the culture of Lilies; and had long ago come to the conclusion—as they were especial pets of mine—that I had overrated them, and inferred neglect when there was really none. For more than thirty years I have grown all the principal sorts that could be obtained in European collections, and, without mentioning the regular autumn trade sorts, have had all that were really hardy in our climate; but my real pets have been the Japan sorts of the speciosum type, introduced by Dr. Siebold. These have been erroneously known under the name of lancifolium, and its different varieties, as rubrum, album, roseum, and punctatum. The first was crimson spotted, the second fine white, the third rose spotted, and the last blush or pink spotted. Of these I have ever been curious to know in what manner the punctatum originated, as it has a habit which none of the others has. It always comes up in the bed several days before the others, keeps ahead, and flowers fully a fortnight sooner than they do. So much in advance, indeed, is it, that I have had the shoots badly nipped by late frosts when the others, just coming out of the ground, were not in the least injured. In fact, after some disappointment and trial of two or three years, I took it out of my show bed, as it spoiled the general effect, by the decay and loss of its flowers, leaving only bare stems when the other varieties were in their prime. My first strong bulbs of these Lilies were purchased of the late Mr. Groom, whose nursery at Clapham I visited when in London in August, 1844. I selected the bulbs then in bloom, paying him £5 for speciosum (lancifolium rubrum as he called it), and £2 each for album and punctatum, and these were sent to Boston to me as soon as they were in condition to move. They came to hand late in November, but in fine order, and were carefully potted and treated, placing them in a cool house until

they began to grow, re-potting them when they required it, and in June following they flowered in great perfection. Each plant bore from fifteen to twenty flowers, which were admired by all who saw them. These Lilies, at that time, were very rare, and so striking was the speciosum that I made a drawing of the plant as it stood in the pot, and an engraving of it appeared in my "Magazine of Horticulture," for January, 1848 (Vol. XIV., p. 36). At that early period the hardiness of these Lilies in our severe climate had not been tested, and as the bulbs were rather too expensive to make the trial, it occurred to me to save their seed, and to ascertain in that way whether they were hardy or not. Of course, my first object was to hybridise; but, as I had then only the album, punctatum having done blooming, speciosum was fertilised with album, and *vice versa*. The result was that every individual blossom produced a pod of fine plump seed, and in three or four years we had many thousand seedling bulbs, fully grown and in bloom. Seeing how readily fertilisation was effected, I thought I would try still further to ensure hardiness, and next season I potted bulbs of tigrinum, canadense, superbum, longiflorum, and candidum, so as to have them in bloom at the same period as speciosum. All succeeded, and I had no fewer than twelve packets of seed, the result of fertilisation, from which I raised the finest of all the Lilies of the type yet produced, including the variety known as Melpomene, each petal of which is completely covered with blood-red, excepting a clear white border on every petal, and the papillæ which are of a black-crimson. In some of the hybrids the form was completely ruined, such as candidum and longiflorum; but the old speciosum album, fertilised with tigrinum, yielded very beautiful deep-coloured flowers. For upwards of fifteen years I continued to grow these Lilies from seed, and produced many fine kinds; but none to exceed Melpomene.

In 1862, *L. auratum* was introduced to this country. Simultaneously with its introduction to Britain it flowered with Mr. Francis Parkman, now president of the Massachusetts Horticultural Society, and was described in my magazine, where the name of *L. Dexteri* was suggested, as Mr. Dexter brought the bulbs from Japan. Mr. Baker has evidently read the article, as he quotes *L. Dexteri* as a synonym on my authority. It at once occurred to me what a mine of beauty it was, and how much might be worked out of it by crossing it with the speciosum; therefore, begging a single anther of it from my friend Mr. Parkman, I took it home for experiment. I happened to have *L. Melpomene* in bloom, and the flowers of that were properly fertilised with *auratum*, but only one perfected seed (probably from the insufficiency of pollen), and only six or eight perfect seeds were secured. These were duly planted, and in time some six or eight plants were the result. These all bloomed just like the female parent—all, till the last one began to unfold the petals of an immense bud, when a flower was revealed with which *L. auratum* at its best could not compare. It was 12 inches in diameter, of just the form of speciosum, though not half so much reflexed, pure white, with a deep crimson band and deeper coloured papillæ. Like all good things, it was allowed next year to perfect a large number of flowers when it was exhibited, and the following is the report which was given of it:—"The plant, which was 6 feet high, with a stem nearly an inch through at the base, bore eleven flowers, forming a pyramidal spike nearly 2 feet broad, each flower being 12 inches in diameter . . . It is, in fact, a gigantic form of the Japan Lily, and for stateliness, magnificence, and beauty stands unequalled among all the known Lilies."

From 1850 to 1865 I cultivated four beds of Japan Lilies, numbering several thousand bulbs; an awning was erected over the beds, and from August 20 to October 1 they were in fine perfection. *L. Browni* (Van Houtte), is another grand Lily. Is it different from *L. japonicum*? *L. longiflorum* is a fine Lily, but it is not so hardy as candidum or speciosum. A bed of it 50 feet long, loaded with its great trumpet-shaped fine white flowers, is a glorious sight. *L. eximium* is too much like longiform, *i.e.*, if I had the true sort from Van Houtte. *L. Takesima* is a great improvement on longiflorum; it produces more flowers, and the outside of the petals have a slight brownish tinge. *L. testaceum* is a desir-

able Lily, but its lanky stem and meagre foliage detract from its otherwise good qualities, particularly the very distinct colour of the flowers. Our American Lilies are very showy and beautiful, but their treatment is often misunderstood, as the bulbs of our Eastern sorts are all annual, flowering but once. Our botanical works say nothing of this, and a great many years ago I failed to bloom them, as I set out the old bulbs. I soon, however, discovered my error when digging them from their native woods; and, again, they are fastidious as to soil. They never do well in loam, and only flourish in a very loose peaty earth, in which American plants are generally grown. *L. canadense* and *L. superbum* will succeed in any wet place; but *L. philadelphicum* will only thrive in a comparatively dry situation. In July, 1873, I dug up bulbs of the latter in their native habitats, by the sides of roads and in peaty pastures, in full bloom. These were laid in a box of sandy peat until October, when they were planted for convenience in boxes a foot square and 6 inches deep, and last July they all flowered beautifully and produced a quantity of seeds. Its deep orange-crimson flowers spotted with black-purple, erect habit, and tiny foliage, make it very attractive; bulbs of it not much larger than a Pea often produce one flower. *L. canadense* is indigenous in my grounds, where I have dug up quantities before they were cleared and planted, and even now, where a spot is neglected for two or three years, plants of it spring up, showing their nodding yellow-spotted flowers, probably from scales, dormant bulbs or seeds lying in the soil. *L. superbum*, our grand Lily, might well be taken for an improved variety of *canadense*, as the only material variation is the size of the flowers, their deeper colour, and its more reflexed petals. Mr. Baker, I think, commits an error where he states that the "Bulbs are large, cæspitose, globose, perennial." This is not so; the bulbs are not globose, nor perennial. In fact, this Lily is precisely the same as *canadense*; the bulb flowers but once, and emits a runner to take its place. I have been through swamps in which it grew 7 feet high, with from ten to twenty flowers; I have dug up hundreds of bulbs of it, and had a bed 80 feet long and 5 feet wide of *superbum* and *canadense* for nearly ten years. You will almost always see the old dry stalk standing about 4 inches from the new shoot, and anyone knowing the habits of this Lily can dig it at any time after flowering, before frost, from the old dry flower-stems. They grow most abundantly among thickly-matted roots in peaty swamps, where it is almost impossible to dig them except by means of a sharp hatchet and very strong spade. Mr. Baker could not have had for his description a true *superbum*, of which I should be glad to send him bulbs, direct from their native haunts.

It is singular that none of our cultivators have had much success with the Californian Lilies. *Humboldti* and *Washingtonianum* have been sent to us in quantity, but we have never yet had the good luck to see a flower. Probably they are not hardy enough for us, and under pot culture we have not yet succeeded. We hope for better things in the future. A valuable addition to your article would be an alphabetical arrangement of the varieties and synonyms in the reference to the species as designed by Mr. Baker.

Boston, May 1st, 1875.

LILIUM WASHINGTONIANUM.

PERHAPS I can, by stating a few facts, throw some light on the much-vexed question as to *L. Washingtonianum* and its varieties. It was I who first introduced the plant in 1869. The bulbs were gathered in the Sierra, photographs taken of the flowering stems at San Francisco, and, if I remember rightly, a comparison made with Dr. Kellogg's specimen. Now, some of these bulbs measured as much as 5 inches through, and had flowered with as many as seventeen blooms; but, owing to the requirements of the plant, which I did not fully know, even the strongest bulbs produced only from three to five flowers, which were very fragrant, tipped with white, and scarcely changing to rosy-violet; the leaves were glaucous. Afterwards I received from Oregon a bulb as *L. Washingtonianum*, which had a flower-stem like the Lily figured in THE GARDEN (p. 300). The flowers were white, changing rapidly to a beautiful rosy-violet, much brighter than that of the flowers of those imported in 1869; the substance of the flowers was also better; the leaves were not so

glaucous, but a good green. I am of opinion with Mr. Wilson, that the plant is very variable, and produces forms running into each other to such an extent that it is somewhat difficult to see which is the typical form. I suppose the specimen figured at p. 343 has been found growing under circumstances very favourable to its development. I doubt, however, whether there are bulbs of this peculiar species now in Europe, or whether this very obstinate species will ever be brought to perfection. I had *L. purpureum* from one of Stevens's sales, but there is not a "satiny bright purple" in the flower, but rather a dull rosy-violet. But this "sub-species" or variety of *L. Washingtonianum*, on the authority of Mr. Baker, is of easy cultivation. Messrs. Sievers & Miller, of San Francisco, called it the "Eel River" variety. The leaves are a very dark bronze-green in colour. The question will be settled soon, when the plants will be in flower side by side, and will be carefully studied by those engaged and interested in Mr. Elwes' great Lily work. *L. Bloomerianum* is another name given to *Humboldti* by Dr. Kellogg, but the name *Humboldti*, having been provisionally given by Roezl and the description made by M. Duchatre in 1870, claims priority. *L. Humboldti ascellatum* is said to be a fine variety. Permit me to add that, since the above was written, I have had more positive information than my own in reference to *L. Washingtonianum*; and it appears, after all, that Mr. Wilson is perfectly correct in his assertions—viz., that there is—1. *L. Washingtonianum*, properly so called—that one named and described by Dr. Kellogg, which in itself varies much in substance and in the colour of the flowers, according to soil, situation, and geographical distribution. 2. *L. Washingtonianum* (*Eel River* variety), flowering in an umbel, like the figure on p. 300, and of a dull rosy-lilac-purple, and having reflexed petals. *L. purpureum*, of a satiny-purple, changing to bright lilac, as stated by Mr. Bull, the petals being very much reflexed and raceme-flowered. Whether or not these three different plants are to be regarded as species, properly so called, as sub-species, or as varieties, will doubtless be settled by careful examination this summer.

MAX LEICHTLIN.

Baden Baden.

LARGE-FLOWERED THRIFT.

(*ARMERIA MAURITANICA*.)

THE plant, of which the illustration (see p. 419) is a representation, and of which we here give a flower head of the natural size, is superior in appearance to all others of the same genus, and well worth a place in every garden. It is sometimes confounded with *Armeria*

Large-flowered Thrift (natural size).

plantaginea, which, however, is perfectly distinct from it, and inferior to it as regards size of flowers, brilliancy of colour, and size of foliage. It requires a light sandy soil, and, if its roots be covered during winter with a mulching of dry leaves, it may be left out of doors all the year round with impunity. It flowers in May and June; and its propagation is effected by division, or it may be raised from seed.

F.

The Fragrance of Flowers.—Sometimes the sweetest flowers we have, like *Mignonette* and *Sweet Peas*, are entirely destitute of fragrance. This occurs on particular days or portions of days, and may be caused by a peculiar condition of the atmosphere; but we have known a bed of *Mignonette* to be destitute of fragrance for a whole season, for which we could give no satisfactory reason.—JAMES VICK.

THE INDOOR GARDEN.

THE AURICULA.

THE Auricula is a plant that must be grown by itself; one cannot mix it up with others. It needs a low, shaded, cool house, or a cold frame in an airy position; it requires special treatment, and must have it if the cultivator is to succeed with it. We attended the annual exhibition of the National Auricula Society, held the other day at Manchester, where a great number of plants were staged in the several classes; but, with the exception of some from that well-known cultivator, Mr. Turner, Royal Nursery, Slough, all the plants came from Lancashire and Yorkshire. Cultivators of Auriculas in these two counties assert that they are deluged with applications for spare plants from anxious purchasers. They also state that the taste for the Auricula, which for a time declined, is now rapidly increasing, and that this time the old-fashioned flower is the subject of a very pleasing revival—a gratifying piece of information.

Show Auriculas.—These are so named to distinguish them from the Alpine section. Show Auriculas are divided into four classes, viz., grey-edged, white-edged, green-edged, and selfs. A flower of either of the three former should have a yellow or golden centre or throat; round this a zone of pure white, which is covered with a dry mealy substance, known as the paste; then a ring of what is known as the body colour, generally a shade of violet, purple, plum, red, or maroon; and then the edging, which is also covered with a slight paste. The grey and white-edged flowers come very near to each other, and it is only a practised cultivator who can distinguish the merely technical difference between them. On the other hand, the green-edged flowers are quite distinct in character; the edge is of a lively pea green, with a slight powdering of meal, more or less dense according to the variety. One of these flowers must be looked into to perceive its great beauty, and its marked individuality of character. It is a flower that may be said to invite inspection; it must not be passed by as one would a flower whose properties can be detected at one glance. The self flowers have a white ground colour, with a broad marginal body colour of yellow, violet, mauve, red, purple, maroon, velvet, &c.

Culture of the Auricula.—This is by no means a difficult process, but he who would succeed must be attentive and painstaking. The show Auricula requires pot culture, and a soil rich in vegetable mould, or stable manure, or cow-dung well rotted and dried sufficiently, so that it can be rubbed to pieces by the hand, mingled with a good and rather strong yellow loam, and with the addition of some silver-sand or peat earth to keep it porous. Some pieces of turf cut from a pasture, and allowed to lie for a year or two to become rotten, should be added, and the compost should be well mixed together, and turned and exposed to the open air before using it. It need not be very fine; lumps of fibry matter are a good thing in Auricula soil, according to the testimony of one of our most successful cultivators, the roots spread more readily in it, and the plants do better in consequence. In potting, the collar of the plant should be even with the surface of the soil; and, in the act of potting, any leaf showing symptoms of decay should be removed.

Propagation.—Auriculas may be raised from seed, and named varieties by division of the roots. The Auricula throws up side-shoots from the collar of the plant, generally just beneath the soil. It is the rule to remove these soon after the blooming plants have done flowering, and when the old leaves begin to decay. Generally, they will be found to have small pieces of root adhering to them; but, even if they have not yet sent out rootlets, they will soon strike root. These small side-shoots should be put singly in small pots, using the Auricula soil above mentioned, which should be pressed firmly about them, and the shoots put into a frame in a cool shady spot and kept from the sun. A slight sprinkling will be all that is required in the way of water.

Treatment after Flowering.—As soon as the Auriculas have done flowering, which is generally by the middle or end of May, it is the usual custom with some cultivators, to set the plants out of doors on a dry hard bottom, where the plants can receive all weathers but the mid-day sun, until July, by which time they will have perfected the side-growths referred to above, when they can be removed and potted as already directed, and the parent plants protected from heavy rains. Others keep their plants in cold frames during the summer, and do not expose them, especially in the south of England. In August, the plants are turned out of the pots, the soil shaken out, the roots examined, and all injured, cankered, or diseased ones removed, and then re-potted in new soil. After potting, the plants are slightly watered, and put into a cold frame.

Autumn and Winter Treatment.—Good drainage is indispensable to the Auricula; therefore, in potting put a good number of broken crocks at the bottom of the pots, for an efficient drainage has much to do with the well-being of the plants during the autumn and

winter when they are at rest. The frame in which the plants are placed after potting should be dry and airy; hence it is that Auricula cultivators have frames specially constructed for the purpose. The elevation is higher than ordinary frames, with wooden shelves up near the glass, and so fixed that there can be a free circulation of air beneath them. Damp is a great enemy to the Auricula during the winter; at the same time, a dry artificial heat would be even more injurious. In open weather the plants should have all the air that can be given them; but, in damp weather, or times of severe frost, or during the prevalence of nipping easterly winds, let them be kept closer. The plants must be occasionally examined, to remove any decaying leaves or signs of damp. But little water is required in winter time, and only when the soil is quite dry about the roots. Give water on a sunny mild day, and stand the plants outside of the frame, when it is administered, so as to keep the interior of the frame as dry as possible. We have here endeavoured to lay down certain general rules. There are many minor points which are soon learned by cultivators, for there is nothing like the teachings of experience in achieving the successful culture of plants.

The Alpine Auricula.—It is supposed that the show Auricula is a variety of the Alpine, though there appears to be almost specific differences between them. The Alpine is of a hardy constitution, and the commoner forms will do well in the open border. Of late years a great improvement has taken place in this lovely flower, and Mr. Charles Turner, of Slough, has been eminently successful in raising new and improved varieties. By strict Auricula fanciers, and at the exhibitions of the National Auricula Society, the Alpine section is divided into two classes, viz., those with golden, and those with white centres. What appears to be an arbitrary distinction is set up, for it is required for exhibition purposes that the flowers with yellow centres should have two-coloured margins, a dark body colour paling off to a lighter hue, as for instance, purple to mauve; a plain to lilac-pink; while the white-centred flower must have a marginal wholly of one hue. There must be in the first what the northern growers term shading; but the second section must be destitute of it. Mr. Turner has raised many splendid varieties that set these laws—laws as far as the exact northern florists are concerned—altogether at defiance, and they are really grand from a decorative point of view. We have now in our conservatory, doing well under the shade of large plants, certain Alpine Auriculas growing in pots, some having golden, and some white centres; and they are the admiration of every one who sees them. They are seedlings raised in a very simple manner.

Raising Seedlings.—Make up a fine soil—loam, leaf mould, and sand—and put it in a well-drained pan or shallow box, and then sprinkle the seed thinly over it, and gently press it into the soil. Then carefully sprinkle the surface with water, place a piece of glass over the pan, and put it away in a cool frame, or under a hand-glass in a shady spot, and in a few weeks the young plants begin to appear. Sow in March or April if possible; the earlier in the year the seedlings are raised, the larger and stronger will be the plants when they come into bloom a twelvemonth later. As soon as the plants are large enough to handle, let them be pricked off into pans to encourage their growth, and later on potted singly into small pots, and wintered in a cold frame. When they flower, all the best should be marked, and kept for cultivation in pots; the inferior varieties should be planted out as border flowers, and when they become established they make very efficient border flowers.—“Land and Water.”

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Standard Fuchsias.—Standards with a clean stem, 1, 2, or 3 feet high, and a good bushy head, are very suitable for placing amongst other plants, as, for example, in the centre of a group, where nothing but the top is seen. To obtain them in this form, when struck from cuttings, the points should not be taken out, but should be allowed to proceed upwards to the desired height, when they may be stopped, and the side-shoots soon form a head. Growths which may appear on the lower part of the stem should be rubbed off, and a strong clean stake should be put to each plant to keep the stem straight and to support the head.—M.

The Peach Palm.—Pupúnha, or Peach Palm (*Bactris Gachipaës*), is one of the most beautiful and useful of Palms of the Amazon, growing generally in clusters from 60 to 90 feet high, and thickly armed with prickles. Its numerous drooping leaves, 7 feet long, have from sixty to seventy pairs of leaflets pointing in all directions. Under the deep green vault hangs the huge cluster of fruit, yellow and red when ripe, about seventy-five in number, and making a load for a strong man. It is, according to the “Scientific American,” nowhere found wild, but is seen in cultivated spots along the whole river.

Lilium Kramerii.—In a letter recently written by Mr. Hogg, from Japan, to his brother, the editor of the “American Garden,” he says:—“Besides *L. auratum* another new Lily has been found. Some two or three years ago the first of them were sent to England and, I believe, it has there been named *L. Kramerii*. Its general character is that of *L. longiflorum*, of which eventually it may prove a variety; only its flowers, instead of being white, are of varying shades of pink colour. Coming from the southern part of Japan, it probably will not prove hardy; but for greenhouse or frame culture it will be an acquisition of no little merit, owing to its beautiful shades of colour.”

THE WINDFLOWERS.

At this season, when the fields, and hills, and gardens, of Europe owe so much of their beauty to the *Anemones*, a series of illustrations of such species as are in cultivation will no doubt be of interest to all who grow hardy flowers.

White Windflower (*Anemone alba*).—This is best described as a dwarf and stout *Anemone sylvestris*, and is a native of Dauria, Russian Asia, the Crimea, and, doubtless, the Caucasus. The leaves are only a few inches high, and the handsome white flowers, somewhat like those of the fine large-flowered variety of *Clematis montana*, rise an inch or two above them. Till plentiful, it should be grown in deep fibry loam on the rock-work. Flowers in summer; 4 to 6 inches high. Propagated by division and by seeds. The figure of this in the "Botanical Magazine," 47, 2,167, does not do justice to the plant, and we have been unable to find a specimen of it to figure.

Alpine Windflower (*Anemone alpina*).—This is almost too stately to be classed with the dwarf plants that we usually term Alpines; but high on nearly every great mountain range in northern and temperate climes it is one of the most frequent and best-marked plants. It may be seen in every stage on the same day, and on the lower terraces of the great mountains and in the green slopes of the valleys it assumes somewhat about the same proportions as in our gardens. It is distinct from most of its cultivated brethren in its large and much-cut leaves, its size, and the very soft down on the exterior of its flowers. The interior of the flower is white, the outside being frequently tinted with pale purplish-blue. It grows from 4 to 18 inches and even 2 feet high. Being of a vigorous character it should, if placed on rock-work, have a level spot with abundance

The Alpine Windflower.

Flower of the Alpine Windflower.

of soil to grow in; and, being also tall for an Alpine plant, it would be the better of close association with neat shrubs, plants of the stature of the vernal *Adonis*, and the better kinds of *Aquilegia*. They would afford each other protection. Where the soil is good it grows quite freely as a border plant; it flowers in its native country as the snow disappears, and in our gardens in the end of April or beginning of May. When plants are well established in good soil they may be taken up and readily divided with advantage to themselves; it may also be raised from seed. Visitors to the Alps might bring home quantities of the seed, which ought to be sown as soon as possible after being gathered. Sometimes the flowers are yellow, in which state the plant is often known as *A. sulphurea*.

Great Hepatica (*Anemone angulosa*).—Every one who knows the charmingly bright flowers of the variously coloured varieties of the common *Hepatica*—the very bravest of our early spring flowers—will welcome this species, fully twice the size of the common *Hepatica* in all its parts, with flowers of a fine sky-blue, as large as a crown piece, and distinguished from the common kind by its five-lobed and toothed leaves. It is a native of Transylvania, and hardy everywhere throughout these islands. Obviously the only thing to determine about such a valuable addition is how to best grow and enjoy it. It is naturally more an inhabitant of the elevated copse than the crest of the Alps, and is not able to flourish when thoroughly exposed to the fiercest blasts, like the little Alpine plants that cushion down their stout, if diminutive, leaves shorter than the very Moss, so that injury from the fiercest gale is out of the question. I have seen it in sandy soil in a thin shrubbery attain a height of more than a foot when not in flower, and the shelter and slight shade received from surrounding objects is decidedly favourable to its development. In all properly formed rock-works, or in their immediate vicinity, it will be possible to give

it a suitable position; while in spaces between American plants and choice dwarf shrubs in beds it will succeed to perfection. When plentiful enough, it may be used as an edging to beds of choice spring-flowering shrubs, and for planting in wild open spots in shrubberies, or in open, rather bare, and unmown spots along the margins of wood walks. Let us hope that time will see it sport into several colours like its relative, our common *Hepatica*, one of the oldest, as well as brightest, inhabitants of English gardens.

Apennine Windflower (*Anemone appennina*).—This has erect flowers of a bright sky-blue. These star-like flowers are larger in

The Large-flowered Hepatica.

The Apennine Windflower.

size than a half-crown piece, and are paler on the outside than within. The plants grow in dense tufts, so that, though there is but one flower to a stem, they are thickly scattered over the low cushion of soft green leaves. Although figured in most of our works on British plants, and naturalised at Wimbledon Park, Cullen in Banffshire, Tonbridge Castle in Kent, and various other places, amidst the groves and shrubberies of all parts of these islands, it is welcome in the garden and on the rock-work; but it will be only when we see it scattered amongst and contrasting with the natives *Anemones* in our woods, or making glorious mixtures of gold and blue with the Buttercup-like Windflower in open spots along shrubbery walks, or running wild among any other dwarf plants with which the woods or pleasure-grounds are graced, that we shall be able to realise the fact that this Italian beauty can add a new charm to the British spring. The Apennine *Anemone* flowers in March and April, is very readily increased by division, and grows about 4 to 6 inches in height.

Winter Windflower (*Anemone blanda*).—This is a near relative of the Apennine Windflower, and a very lovely plant, deserving to be cultivated in every garden in the British Isles. It is of a fine deep sky-blue, like *A. appennina*, and has larger and more finely-rayed flowers, dwarfer, harder, and smoother leaves, and blooms in the very dawn of earliest spring, during mild open winters, and in warm parts showing as early as Christmas, flowering continuously

The Winter Windflower.

too, so that it may be seen in flower late in spring with its relative *A. appennina*. It is perfectly hardy and vigorous, and, from the harder and smoother texture of the leaves, can stand exposure to cutting winds and sleets even better than the very hardy Apennine *Anemone*. In a word, it combines every good quality of a hardy Alpine plant; should be grown on every rock-work, or planted on bare banks that catch the early sun in the pleasure-ground; should adorn the spring garden, and, when sufficiently plentiful, might be naturalised in

half-wild places along with other free and hardy members of its charming family. It does not grow more than 4 inches high, and is multiplied easily by division. Botanically this is chiefly distinguished from *A. apennina* by its carpels being topped with a black-pointed style, and by the sepals being smooth on the outside.

Poppy Anemone (*Anemone coronaria*).—A native of sub-humid pastures in the south of Europe, this plant has been one of the most

A Florist's Anemone.

popular in our gardens from the very earliest times. There are a great number of varieties, both single and double, all worthy of cultivation, and great ornaments of the spring garden. The single sorts may be readily grown from seeds, and they should be thus raised by those wishing a large stock of effective spring flowers. Infinitely

A. coronaria (single).

A. coronaria (double).

varied as they are in colour, and possessing most vigorous constitutions, they deserve to be cultivated even more than many double varieties annually offered by our seedsmen. The plantation of these double varieties may be made in autumn, or in spring, or at intervals all through the year, to secure a continuity of flowers; but the best bloom is secured by September or October planting. The Poppy Anemone does best in a rich deep loam, but is not very fastidious. The roots of the more select kinds may be taken up when the leaves die down; but they are in few cases worth this special attention, simply because many splendid varieties may be grown as readily as any native herbaceous plant, and we had better cultivate new and distinct species of hardy plants rather than the numerous varieties of one kind. If the seed be sown in June, and the plants pricked out in autumn, they will flower very well the following spring, so that this fine old plant may be said to be almost as easily raised as an annual. Flowers in April and May, and often through the winter; red, white,

and purple, in variety. Height, 6 to 9 inches. Propagated readily by seed or division.

Scarlet Windflower (*Anemone fulgens*).—The white Lily is not more conspicuous for its purity among the border flowers of summer than this plant for its fiery brilliancy amidst the flowers of spring. It is perfectly hardy—vigorous too—the large scarlet flowers being boldly supported on stems about a foot high, springing from a dwarf mass of hard deeply lobed and toothed leaves. A native of Greece and Southern Europe, it is by no means common in gardens, and is, indeed, unknown to the majority even of those who grow and care for spring flowers; but it will ere long become popular, being one of the noblest ornaments of spring, and, as a scarlet flower, almost unrivalled. It is admirably suited for culture

The Scarlet Windflower.

Haller's Windflower.

as a border plant, indispensable for the rock-work and spring garden, and, when sufficiently abundant, may be tried amongst the other Anemones scattered about in half wild places. Flowers in April and May; vivid scarlet. Height, 1 foot. Propagated by division or by seeds.

Haller's Windflower (*Anemone Halleri*).—This at first sight closely resembles the Pasque-flower, but it is smaller, and the leaves are not nearly so finely divided. We have never seen it growing, but there is an excellent figure of it in "Loddige's Botanical Cabinet," t. 940, where it is described as having been found by Albert Haller in the St. Nicholas Valley of the upper Vallair, and it is said to be also found in Dauphine, Piedmont, and in the Eastern Pyrenees.

Common Hepatica (*Anemone Hepatica*).—To add perfume to the Violet, paint the Lily, or gild the yellow Crocus, would seem to be no more wasteful excess than to praise this exquisite little flower. There is a cheerfulness and a courage about it on warm sunny borders in spring which no other flowers possess; it is hardy everywhere, is not fastidious as to soil, though it loves a deep loam, and presents a charming diversity of colour. The principal varieties are

The Common Hepatica.

the single blue, double blue, single white, single red, double red, single pink (carnea), single mauve purple (Barlowi), crimson (splendens), and lilac (lilacina). Every variety of the common Hepatica is worthy of care and culture. Is it possible to imagine a more beautiful picture than we may produce by planting a mixed

edging of the various colours round say a bed of dwarf American plants, occupying space that perhaps would otherwise be naked? It is but one of many ways in which we may tastefully use them. The plant is a native of many hilly parts of Europe, usually found in half-shady positions, which will be found to suit it best in a cultivated state also. It is readily increased by division or by seeds, the double kinds by division only.

The Autumn Windflower (*Anemone japonica*).—This is one of the most stately and beautiful of all the species of Windflower with which we are acquainted, having a close-tufted habit, and its numerous flower-stems rise to an height of from 18 inches to 2 feet. The individual flowers often measure fully 2 inches across, and are of a

Anemone japonica.

clear rosy-purple colour. As an herbaceous plant, or for pot culture, this is one of the best of Anemones. A fine white-flowered variety of it is known as *A. japonica alba*, or *Honorine Jobert*, a kind even more

Anemone japonica alba.

beautiful than the rosy-flowered form. It is said to be a sport from *A. japonica* and not a hybrid as some have imagined.

The Narcissus-flowered Anemone (*Anemone narcissiflora*).—This belongs to a group which bears white flowers on umbellate scapes, and of which *A. rivularis*, *A. obtusiloba*, and *A. pennsylvanica*

may be cited as examples. It differs from all these, however, in having much more finely-divided leaves, and it is a kind which well deserves cultivation.

Wood Anemone (*Anemone nemorosa*).—This hardy plant, which not only embellishes the woods of these sea-girt isles in spring

The Narcissus-flowered Anemone.

The Wood Anemone.

but also those of nearly all Europe and Russian Asia, is so abundant in the British Isles that there is little need to plead for its culture. It grows, or will grow, in every wood or copse, dotting its handsome flowers all over the ground, should other things not interfere, and seeming to invite us to plant other beautiful species of *Anemone* by its side. It has been met with blooming sweetly on some of the very highest and most inaccessible crags of Helvellyn, just under some cliffs where a peregrine falcon had built her nest, and very far away from either wood or copse. There are double varieties, and the colour of the flower is occasionally lilac, or reddish, or purplish. A single sky-blue variety is in cultivation, which has flowered densely in a fully exposed position, and produced the most

The Blunt-lobed Windflower.

exquisite cushions of cerulean blue imaginable. One day it may become a popular rock-plant. Flowers from March to May; white, and reddish outside. Height, 6 inches.

Blunt-lobed Windflower (*Anemone obtusiloba*).—This is another beautiful Himalayan species, of dense tufted habit, having large three-lobed coarsely-serrate leaves and umbellate clusters of showy white flowers. It is well figured in the "Botanical Register," vol. 30, t. 65, and is said to be a native of the Choar Mountains, Himalayas, where it not unfrequently grows at an altitude of from 10,000 to 12,000 feet above the sea-level. It is well worth a place in sheltered portions in the rock-garden.

Cyclamen-leaved Anemone (*Anemone palmata*).—A very distinct kind, with leathery, kidney-shaped, slightly-lobed leaves and large handsome flowers, of a glossy golden-yellow, only opening to meet the sun. A native of North Africa, Spain, and other places on the shores of the Mediterranean; this charming flower requires and deserves a little more attention than most of its cultivated sisters. It is especially a rock-work gem, and should be planted thereon in deep turfy peat or light fibrous loam with leaf mould. It should not be placed in positions on the face of rocks suited for Saxifrages and many other plants that are content with mere crevices, and drape the face of the rocks with the slightest encouragement, but rather on level spots, where it could root deeply and spread into firm tufts.

Plants of very rapid growth or rambling habit should not be placed near it, as they might overrun and injure it. There is a double

The Cyclamen-leaved Anemone.

variety, *A. palmata* fl. pl., and a white one, *A. palmata alba*, both now rare. Flowers in May and June; 6 to 8 inches high, and is propagated by division or seeds.

The Spreading Windflower (*Anemone patens*).—This is a dwarf-growing species, tufted in habit, and one which bears creamy-white flowers fully 3 inches in diameter. Its leaves are finely divided, and the floral segments are hairy behind. It is rarely found in cultivation, although it is long since it was introduced. It is

The Spreading Windflower.

figured in the "Botanical Magazine," 45, t. 1,994, and is there said to have come from Siberia, and to have blossomed in Loddige's nursery at Hackney. In habit and mode of flowering it somewhat resembles the Pasque-flower (*A. pulsatilla*).

The Pennsylvanian Windflower (*A. pennsylvanica*).—This is showy kind, which well repays any little extra trouble that may be

The Pennsylvanian Windflower.

taken in cultivating it. Its leaf is like that of a *Ranunculus*, and the flowers themselves are something like those of a large white Buttercup. They often measure nearly an inch across, and are slightly tinted sometimes on the outside of the beautiful spherical buds. It grows about 18 inches high, and blooms freely for many weeks at a time. It is very valuable for cutting, especially for mingling with coloured flowers or green leaves, in a dish or basket.

Peacock Windflower (*Anemone Pavonina*).—This kind is very rarely seen in our gardens, though well worthy of being largely grown. The flowers are smaller than those of the common garden Anemone, but usually very double, from the great number of narrow pointed petals filling up the centre of each. These being of a gorgeous cinnamon-red, the effect is peculiarly rich when the flower opens well on fine days. Sometimes the central petals are green. The plant is a native of the south of Europe, should have a light warm well-drained soil, and is a charming ornament of the rock-work or border. In France I have seen it used with good effect as an edging plant for beds of spring and early summer flowers, but with us it is as yet too scarce to be employed thus. It is, however, rather abundantly grown in gardens in the south of France, and may be readily obtained by our nurserymen. Flowers in May and June; rich red. Height, 6 to 8 inches. Propagated by division at the end of summer or very early in spring. Mr. Niven says this species appears to degenerate from the beauty of the Continental

The Peacock Anemone.

The Pasque-flower.

type after a year's cultivation in our gardens—the petals assuming a greenish character, rendering the plant scarcely worth cultivating.

Pasque-flower (*Anemone Pulsatilla*).—Though sparsely distributed in Britain, this fine old border plant is a true native, and when it does occur on a bleak chalk down, it is generally freely dotted over the turf. The position is usually such as to suggest the aptness of the name Windflower for the family generally; and there are few sights more interesting to the lover of spring flowers than to

The Yellow Wood Anemone.

The Purple-anthered or Rill Windflower.

see its purple bloom just showing through the hard Grass of the blast-swept down on an early spring day. The plant is much smaller in a wild than in a cultivated state, usually devoting itself to the production of a solitary flower, which, while showing through the Grass, seems careful not to rise above it. In the garden it forms rich healthy tufts, and flowers more abundantly and vigorously, the contrasts between the wild and cultivated state of the plants being very marked. There are several varieties, including red, lilac, and white kinds, but these are now rare. There is also a double variety. It prefers well-drained and light, but deep, soil. Flowers in March, April, May; purplish. Height, 3 to 12 inches. Propagated by division or by seeds.

Yellow Wood Anemone (*Anemone ranunculoides*).—Not unlike the Apennine and the common Wood Anemone in habit, this species is so very distinct in its clear golden flowers that it is well

worthy of cultivation even by the side of the most admired kinds. Indeed, we may consider it an Apennine or a Wood Anemone done in gold! It is a South European species, and apparently is not so free on the generality of our soils as the blue Anemone, but when grown into well-established tufts on a light or warm and well-drained soil, it displays qualities of which those who have merely seen isolated plants or figures of the plant can have no idea. I have not found it do well on clay soil, but on chalky soil it seems to grow as freely as the common Crowfoot. It is quite charming for association with tufts of the Apennine or the Wood Anemone, the Pasque-flower, any of the varieties of *Anemone Hepatica*, the *Aubrietias*, and like plants. It comes in among the naturalised group of British plants, and grows in a semi-wild condition at Abbot's Langley in Herts., near Worksop in Notts., and it is also reported to occur in several other counties. It is one of the many beautiful hardy plants that may be freely naturalised in our woods and shrubberies. Flowers in the end of March and beginning of April. Height, 4 to 6 inches. Propagated readily by division, and also by seeds.

Purple-anthered or Rill Windflower (*Anemone rivularis*).—This is not unfrequently met with in good collections of hardy perennials. It bears star-like white-sepalled purple-anthered flowers on compound umbellate scapes. The leaves are sub-entire, and rather indistinctly fine lobed. The purple anthers and smooth purple peduncles serve to distinguish it from others of the distinct habited group to which it belongs. It is figured in the "Botanical Register," vol. 28, t. 8, and is said to be a native of the north of India. It is sometimes erroneously called *A. longiscapa* in gardens (Wallich's Catalogue, No. 4,691), but that species has reniform five-lobed leaves with shaggy foot-stalks and umbellate flowers, and is more nearly related to *A. narcissiflora*.

Starry Windflower (*Anemone stellata*).—This native of Southern Germany, France, Italy, and Greece, if not so showy, is

The Starry Windflower.

The Snowdrop Windflower.

quite as beautiful as the common garden Anemone. The star-like flowers—ruby, rosy-purple, rosy, or whitish—springing from the much-dissected leaves, vary in a very charming way, and usually have a large white eye at the base, which contrasts agreeably with the gay or delicate coloration of the rest of the petals, and with the rich brownish-violet of the stamens and styles that occupy the centre of the flower. It is not so vigorous in constitution as the Poppy Anemone, and requires a little more care than that does; but this will only make it the more interesting to all who love variety in their collections of hardy plants. It likes a sheltered yet warm position, a light, sandy, well-drained soil, and seems to make little or no progress on heavy clay soils. It is suitable for association with the choicer kinds of Anemone on the rock-work, the mixed border, and the choice spring garden, and should be grown in every garden where spring flowers are appreciated. Flowers in May; height, 10 inches. Propagated by division or by seeds.

Snowdrop Windflower (*Anemone sylvestris*).—A free-growing and handsome species, partaking somewhat of the size and vigour of the Alpine or Japanese Anemone, and the neatness of habit and densely-blooming qualities of the dwarfed kinds. It grows vigorously on almost any soil; the handsome, pure white flowers, as large as a crown piece, being freely produced over a mass of fresh green leaves. A native of Siberia, North Italy, Germany, and France, it is perfectly at home in this country, should be grown wherever first-rate border flowers are appreciated, will associate well with the Alpine Windflower, and plants of like size, about the lower and flatter parts of the rock-work, and, being naturally a native of the grove, will be found perfectly at home along our wood walks and half-wild spots, in

shrubberies, &c. The aspect of the drooping unopened buds has suggested its English name—the Snowdrop Anemone. Flowers in April and May; pure white. Height, 1 foot to 15 inches. Propagated readily by division of root.

Three-leaved Wood Anemone (*Anemone trifolia*).—This is an interesting little species, much like the Wood Anemone, but not so widely distributed. Although found in a wild state in pleasant

The Shaggy Pasque-flower.

The Rue Anemone.

groves on the woody hillsides of Piedmont or the Tyrol, it does perfectly well in our climate, and should be grown everywhere for variety's sake. It may be readily known from its relative, the Wood Anemone, by its neatly toothed trifoliate leaves, and it seems to be a little smaller and dwarfer in habit. I have, however, never seen them under exactly like conditions. It is well suited for naturalisation along with *A. apennina* and others of the family, and is, of course, suitable for rock-work or borders. Flowers in April and May; white. Height, 4 to 6 inches. Propagated by division and by seeds. We could not succeed in getting a living specimen of this for illustration near London.

Shaggy Pasque-flower (*Anemone vernalis*).—One of the Pasque-flower division of the Anemone family, but very dwarf. The flowers are very large and shaggy, and covered with brownish silky hairs. It is a rare plant, and should be grown in some select spot on the rock-work, giving it good drainage and deep soil. A native of Norway, Sweden, and extreme northern countries, and also of very elevated positions on the Alps and Pyrenees, and is rarely seen in good condition in our gardens. It should, as a rule, be grown on a level spot on rock-work, in deep free soil, and be abundantly supplied with water in summer. Flowers early in spring; whitish inside. Height, 4 to 8 inches. Propagated by division and by seeds.

Rue Anemone (*Anemone thalictroides*).—This is more correctly a *Thalictrum* than an Anemone, but the flowers are very like miniature Anemones. It is a delicate, diminutive, and interesting species, with the "habit and frondescence of *Isopyrum*, the inflorescence of

The Vine-leaved Anemone.

Anemone, and the fruit of *Thalictrum*." These qualities, in addition to its dwarf habit, usually only a few inches high, make it worthy of cultivation. The flowers are white, nearly an inch in diameter, open in April and May, the flower-stems bearing a few leaves near the summit, so as to form a sort of whorl round the flowers. It is a native

of many parts of North America, and is increased by seed or by the division of its tuberous roots. There is a pretty double variety, with the flowers somewhat smaller than those of the single one, and very neat. Being small and fragile in its parts, it requires a little more care than most of its brethren, should have a light, peaty, and moist soil, and be associated with other delicate growers, or placed in a position where it is not liable to be overrun by coarse neighbours.

The Vine-leaved Anemone (*Anemone vitifolia*).—As regards mode of growth and flowering, this closely resembles the Japanese Anemone, before alluded to, but is much more downy, and it flowers a fortnight earlier than *A. japonica*. We have seen it flowering in the herbaceous ground at Kew, and consider it well worth cultivation. It is a native of the moist shady valleys of Nepaul, where it is said to be one of the commonest and most beautiful of all wild flowers.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Late Peas.—Peas for late use should now be sown; except in favourable situations, these late sowings are very liable to be affected by mildew, but much may be done to prevent or mitigate the evil. There are several causes that tend to develop this parasite—a want of water, sowing too thickly, and an insufficiency of air; and, if the land is poor, the evil is thus aggravated. For these late crops the most open position in the garden should be chosen, and if the rows are at long distances—say a dozen yards apart—with the intervals occupied by some low-growing crop, a better chance will be afforded them of being benefited by the wind, which is unfavourable to mildew. The ground should be well and deeply manured, so that the roots may have plenty to sustain them through intervals of dry weather; they should also be sown very thinly. By attending to these matters, and never allowing them to want water, which should be so applied as to moisten the soil as far as the roots extend, Peas may be had late; when, with some, they are held as much in estimation as the earliest crops. For the latest crops many advise the small early sorts to be sown, but these are often not satisfactory, as they produce little, and often come in prematurely. Any approved tall kind, such as Emperor of the Marrows or Ne Plus Ultra, will be found to succeed the best.

Vegetable Marrows.—If the weather be warm, these may now be put out in the open ground. See that the plants are thoroughly prepared by gradual hardening in a cold frame, with plenty of air previously, or they will be some time before they make any progress. If hand-lights can be placed over them for a fortnight it will much accelerate their growth, tilting them at the opposite side from which the wind blows in the day-time, and closing down at night. The ground should be made very rich for quick rank-growing plants of this description.

Planting Cauliflowers, Cabbages, &c.—The earliest sown Cauliflowers and Cabbages will shortly be large enough for planting out. These, like most other things, are much better placed where they are to be grown whilst young, instead of being allowed to remain too long in the seed-bed. If the soil in which they are planted is at all dry, give a good soaking before taking them up, by which means they will lift with plenty of roots, and receive proportionately little check. Thin all advancing crops as soon as they require it, and make successional sowings of Spinach, Lettuce, Radishes, and small salad.

Peaches and Nectarines on Open Walls.—Where moveable coping-boards are used these should now be taken down. Examine the trees carefully for greenfly, and on the first appearance of curled leaves immediately wash with tobacco-water, or dust with Pooley's powder; washing is the most effectual means of getting at the insects when rolled up in the leaves; but, whatever method is employed, it should be thoroughly carried out, so as not to require repeating; these insects are later than usual in making their appearance this year. In most places large quantities of fruit have set. Thin at once, but do not at the first operation remove all that can be dispensed with. Amateurs who have not had experience in the cultivation of these fruits are liable to make mistakes in not always leaving those that are best placed for after growth. In seasons like the present, when such an abundance of fruit has set, there need be little difficulty in this matter. All the fruit that is at the off side of the branches, that is, on the side next the walls, should be taken off, as here it obviously cannot have room to swell, unless by loosening the shoots, which is unnecessary when there are plenty at the front. At the time of thinning remove a portion of the superabundant shoots, but let this be done gradually, not stripping the trees of too much leaf at a time, as this has a most injurious effect upon their future strength. Go over the whole with the garden engine or syringe twice a week, giving a good washing with clean water; this will not only prevent

further appearance of Aphides, but will keep in check red spider and thrips; the presence of these is fatal to healthy foliage, without which the fruit can never be equal in size and quality to what it ought to be. There is nothing the amateur cultivates that will better repay attention than these fruits.

Flower Garden, Shrubbery, &c.—*Alternantheras*, *Coleus*, and *Iresines* should now be prepared for planting out in the course of another week. Give them plenty of air and light, and extend this treatment to all tender plants of a sub-tropical nature. See that none of the latter suffer for want of water, as, if their pots are very full of roots, they will require constant attention in this matter; if allowed to become dry, the bottom leaves of soft-growing plants will lose colour—a condition that renders them unsightly through the season. Where carpet-bedding is carried out, all the plants used, except those tender ones named above, should be put in the places they are to occupy, filling the others in afterwards. On all dressed ground, such as herbaceous borders and amongst shrubs, the use of the hoe and rake must be kept up, so that the whole may have a tidy appearance. During the present growing weather, the mowing-machine must be in frequent use, for, if the Grass is allowed to get too long, not only is it objectionable in appearance, but more labour is entailed. Thin out early-sown annuals; the real merits of many beautiful specimens are rarely seen through being often sown in out-of-the-way places, under the drip, shade, and impoverishing influence of the roots of deciduous trees. If, perchance, they happen to get an open situation, where they might have a chance of showing their true character, they are too often allowed only a fourth of the room they require. Let every species and variety have enough room to grow to its full natural size, by which means the flowers will individually be much larger, and the duration of the plants flowering will be considerably extended. Roses should now be mulched with 3 inches of good rotten manure from last year's hotbeds; this, if broken small with the fork, will be less unsightly than that which is not as much decomposed. Mulching under any circumstances does not improve the appearance of the ground's surface, but unless in the very best Rose soils it is a necessity, where the full quantity of well-developed flowers is required; it also assists the perpetual flowering varieties to throw up a succession of bloom. Roses of all descriptions, on their own roots, as well as the different stocks used, are all surface rooters, and when the weather is hot and dry, are, unless mulched, sure to suffer. The cold backward spring we have experienced has had the effect of keeping insects in check; in most places the Rose maggot and aphides have been much later than usual in making their appearance. For the maggot there is no remedy but crushing them with the fingers. This is not nearly so tedious an operation as might be supposed by those who have not had any experience in Rose culture. The insect is easily detected, for, wherever there is a rolled-up leaf it is certain evidence that the grub is present; a very slight pressure will destroy them. Amateurs will find it best to go over their plants once a week (for, wherever the caterpillar exists in quantity, few perfect flowers will open), at the same time dipping the points of the shoots affected with aphides in tobacco-water. A good washing with clean water, applied by the syringe or garden-engine twice a week, will help to keep them free from insects, and also refresh the plants.

Houses.—*Pelargoniums*—show and fancy varieties—will now be fast pushing up their flowers and will be assisted by clear manure-water. For home decoration, it is neither necessary or advisable to tie them out so regularly as when they are intended for exhibition; use only sufficient sticks and ties to support the plants and prevent them having an untidy appearance. For summer and autumn decoration nothing is more useful for amateurs' green-houses than the zonal varieties of *Pelargoniums*; keep these near the glass, so as to induce stout short growth, and do not allow them to become exhausted with flowering at the present time, as they will be much more useful after the show and fancy sorts are over. Pot on young plants of *Balsams*, giving them soil well enriched with a good sprinkling of sand and one-fifth of leaf mould, in which all quick-growing plants of this description root freely. Late herbaceous *Calceolarias* will now be coming into bloom. See that these are free from aphides, or every flower will be crippled. These are gross feeding plants, and delight in manure-water, bearing it stronger than many things. The old but beautiful blue-flowered *Plumbago capensis* should be grown by all amateurs. It is a plant easily managed, and, when in bloom, well bears removal to a dwelling house, where it continues in flower for some time. It is most useful grown in small pots of a 6 or 8-inch size. It will thrive in any soil—loam or peat—sufficiently porous. *Kalosanthes*, which are easily grown and excellent decorative plants, will now require sticks and ties to support their heavy heads of flower that are fast coming to maturity. They are subject to aphides, which get into the points of the shoots and completely spoil the flowers, but are

not easily detected in these plants, except by the yellow hue they give to the leaves; dip in tobacco-water, or smoke any that may be affected. Azaleas will be actively making growth; keep them well syringed, and let the atmosphere be a little closer; a spare pit, if at command, would suit them. If any require potting, give them a shift; these plants are best re-potted when the young shoots have made considerable progress, as, until then, the roots do not begin to move. Do not disturb the roots in potting more than is necessary, and shade from the sun for a fortnight afterwards, keeping the atmosphere moist and close. Amateurs who have not had much experience in Grape growing will generally leave the berries too much crowded in the bunches the first time they are gone over in thinning; as soon as this is seen to be the case more should be taken out without delay, for, if allowed to remain until they get large, they are more difficult to remove, and needlessly waste the strength of the Vines. It is generally from the point of the bunches about midway up that the berries are most pinched for room. Underthinning is a bad practice, each berry being smaller than it otherwise would be if the number in each bunch was sufficiently reduced. Continue to treat, as regards moisture, air, and closing, as advised a few weeks back. When the amateur's greenhouse has Vines over the plants, if kept cool through the winter and allowed to break by the sun's heat, they will by this time have set their fruit and require thinning. All the plants for which room can be found in pits or frames should be removed from under them, so that, as far as possible, each may receive the treatment they require. The greater portion of the plants do not like the shade of the Vines, or the early closing whilst the sun is upon the glass, which is necessary for the Vines, both as a means of bringing on the present crop and ripening the wood for another season. Syringe at the time of closing the house.

Flower Garden and Pleasure Ground.

The removal of spring-flowering plants from the flower beds, in order to give place to summer bedding plants, affords a good opportunity for increasing the former by dividing the old plants, and setting the divisions in suitable situations in the reserve garden, where they should be carefully attended to with water until they have become established; there they should be allowed to remain during the summer months, after which they will be ready to again take their places in the flower beds when the summer bedders have been removed. This applies to all such plants as Aubrieties, Forget-me-nots, Daisies, Polyanthuses, Primroses, &c. Cuttings of double Wallflowers, and similar plants, should now be inserted under hand-glasses; and these, when well-rooted, should also be planted out in the reserve garden. Seed may also be sown now, if it has not already been done, of the various single flowering varieties of this plant. The putting out of summer bedding plants should now be proceeded with as rapidly as possible. It is not by any means necessary that such plants as Verbenas, Lobelias, Golden Feather Pyrethrum, Iresines, Coleuses, Alternantheras, &c., should have been potted off singly, indeed they are generally found to succeed equally well, or, even better, when they are shaken from the store or cutting pots, and planted in the beds at once, or, rather, pricked into the soil with a small dibber, and well watered as the work proceeds. This watering should likewise be repeated every evening, should the weather be dry, until they are fairly established in the beds. Standard Pelargoniums, Fuchsias, Cytisuses, Abutilons, Dracænas, Palms, &c., should all, if necessary, be securely staked as soon as planted, in order to prevent them from being injured by high winds. There are few hardy annual flowers which can be recommended to be associated with the Pelargonium and other bedding plants in the flower garden, chiefly on account of the short time during which some of the most beautiful amongst them remain in bloom. This objection does not as a matter of course apply to such plants as the Amaranthus, Perilla, and a few similar plants, which are grown on account of their ornamental foliage. Many hardy annual flowers, however, are very beautiful, and furnish shades of colour which have not yet been found amongst bedding plants. They are also very useful as marginal plants to shrubbery borders; while, in suitable situations, beds of the various kinds of Asters, and the beautiful varieties of Sweet-scented Stocks, are very effective and interesting, and ought to find a place in every garden. Many of the improved varieties of Phlox Drummondii, too, are exceedingly beautiful, and they, at least, may be used as bedding plants, and have a place assigned to them in the flower garden, as they generally remain in perfection throughout the season. The wintering of the vast numbers of bedding plants which are necessary for properly furnishing the flower beds is found to be a very severe tax upon many garden establishments, more particularly where there is anything like a paucity of glass structures; and the question has been frequently asked if a flower garden could be kept gay

during the entire season or summer months by the use of annual flowers alone. This may certainly to some extent be done, providing a judicious selection of varieties is made in the first instance, and they are afterwards properly managed. For although some of the most beautiful varieties, such as the *Nemophila*, are of short duration, they could nevertheless be succeeded by others which might be had in readiness in the reserve garden, and transferred into the flower garden during showery weather, with comparatively little check. Many others, too, with proper attention would be found to be sufficiently enduring to continue in health and beauty throughout the summer, such, for example, as the *Phloxes* already mentioned, the *Dianthus Heddwigi* and its numerous varieties, several kinds of Stocks, Asters, *Mignonette*, the *Blue Lobelia* (which may be treated as an annual), and many others. The raising of many of these may be accomplished by sowing the seed in a sheltered and suitable situation in the open air during the month of April. Although this would necessarily be attended with considerable delay; but with the aid of a frame or two, and a slight hot-bed, most of the plants just named could be had ready to plant in the beds by the middle of May. And all this could be done at less than a tithe of the trouble and expense which bedding-plants incur. Hardy Ferneries, or rock-gardens, should now have every necessary attention; such as the removal of decayed fronds and weeds, the loosening of the soil, making up of any deficiencies which may have taken place, and the introducing of new, rare, or delicate varieties which it may be found advisable to keep under glass during winter. Evergreen shrubs may yet, if found necessary, be transplanted; and the growth of others may be regulated and cut back, so as to prevent strong-growing sorts from taking possession of space required by more delicate or slower-growing species.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Indoor Fruit Department.

Vines.—As each Vine in the early houses is cleared of its crop the foliage should be thoroughly syringed with clean water, so that any insects that might hinder the ripening of the wood may be washed off. Those parts badly infested with red spider or thrips must be syringed two or three nights in succession, and a thorough drenching with the garden engine or some equally strong power once a-week will greatly help to preserve the foliage, which should be kept as long as possible in a healthy state. Where it is not necessary to close the ventilators for the benefit of tender plants full air may be left on all night in all Vineries after the fruit is cut. Any straggling lateral growths which may have been allowed to grow while the fruit was ripening should be cut in to the part whence it started, so that the buds upon which dependence is placed for next year's crop may have every chance of becoming matured. It is a great advantage at all times, more especially in the case of early forcing, to have the wood completely ripened; and now that the nights are getting milder, air, in small quantities, may be admitted continuously in all Vineries in which Grapes are swelling; this supplies the interior of the house with fresh air, which is more conducive to the free and perfect development of the fruit than a close atmosphere. As soon as syringing is discontinued, to admit of the fruit colouring, the flow pipes may be painted over with sulphur. It is a waste of fuel to light Vinery fires on fine mornings; a little artificial heat in the evening is generally sufficient to keep up the temperature, and a liberal quantity of air should always be admitted in the morning to prevent the temperature from rising too high and scorching the foliage, which is liable to occur.

Pines.—The principal work in Pineries at present consists in airing and damping. On very hot days the pathways should never be allowed to become dry, for an arid atmosphere is not beneficial to many Pines, at whatever stage of growth they may be. Where the plunging material is dry, it should be thoroughly saturated with water. Still shut up early in the afternoons, and a little air should be admitted throughout the night, putting it on at about six o'clock in the evening and gradually increasing it from six o'clock next morning, as it becomes necessary. Keep plants showing fruit successively to the Queens well supplied with water at the root.—J. MUIR.

Hardy Fruit.

The splendid weather of the past three or four weeks has, in a large measure, made up for lost time; and the season, which at one time seemed to be a month later than usual, will now be as early as the average. I do not ever remember such rapid growth as was made recently by all kinds of fruit; the promise of large crops of all sorts is still all that could possibly be desired; and if—as we may now reasonably hope—we escape injury from spring frosts, the labour of thinning the fruit will not be small. Apricots, if not already thinned, should be paid attention to; then Pears and Peaches. The two latter have set their fruit so thickly that delay in doing this will be most injurious to the future welfare of the trees.

Do not yet wholly remove the spray or breastwood from Pears and Plums, but allow it to remain as a screen till the critical period of the 20th to the end of the month is past. Aphides have appeared in large numbers, especially on Cherries and Plums. Peaches, which are usually most subject to their attacks, are, as yet, comparatively clean—a circumstance which is due, no doubt, to the copious washings they have had with the garden engine. This is the best of all remedies, and should be brought into use upon all affected trees. Currants and Gooseberries are at present free from blight, but it is more than likely that caterpillars may attack the latter before the end of the month is out. On their first appearance hand picking, which is always the best and surest remedy, should be resorted to. In many cases grafts put on at the beginning of last month will now be sufficiently advanced to have the clay removed and the ligatures loosened and re-tied somewhat slacker to allow for the expansion of growth. The stocks should have all shoots rubbed off as produced, and the grafts trained into the form desired. Water should be freely given to all recently-planted trees, and Strawberry plantations will be much benefited by repeated waterings from the time the fruit is set to its ripening. I know no other kind of fruit that suffers so much or so soon from drought, or that gives better returns for generous treatment than Strawberries. A piece of ground should now be prepared by trenching deeply and manuring heavily for the purpose of planting out the forced plants; the rows should be 30 inches apart and the plants 24 inches from one another. Previous to planting see that the balls are thoroughly soaked; take out the crocks and, with a pointed stick, slightly loosen the matted roots that they may the more readily take hold of the soil. From such plantations the best crops of fruit will be had next year. Strawberries ought never to occupy the same ground more than two seasons in succession, if quality is desired.—W. WILDSMITH, *Heckfield*.

THE LIBRARY.

THE FERN PARADISE.*

THIS book, the plan of which, we are told, was originally embodied, upwards of a year ago, in three magazine articles, has for its acknowledged object the development of the popular taste for Ferns “in such a way as to lead to the more extensive cultivation of these beautiful plants, not only in our gardens but in our dwelling-houses.” If an enthusiastic appreciation of his subject, a vivid imagination, and splendid powers of description are likely to assist in the accomplishment of the author’s purpose, Mr. Heath will probably have the satisfaction of knowing, in time, that he has been successful; and although we cannot altogether support the claim that is put forward of his having been the originator of the idea of Fern culture in town gardens or in town windows, he is at least extremely likely to aid, to a very wide extent, its full development. His work has evidently been a labour of love; and, wisely choosing to approach his subject from an æsthetic rather than from a scientific point, the opportunity has been afforded of descriptive writing of a nature rarely to be found in works bearing upon botanical matters, which are too often the vehicles for the exhibition of the author’s learning, whilst the more attractive features of the subject are, in a great measure, overlooked. Mr. Heath has divided his book into two distinct parts; the first he devotes to glowing descriptions of the paradise in which the Fern revels when growing in the copses, hedge-rows, valleys, and moorlands of Devonshire; the second relates to the various kinds of Ferns and their culture. In this latter portion enough practical instruction is conveyed to enable anyone who has been laid captive by the charming “word painting” of the earlier chapters of the work, and who has the least possible space, to undertake, with fair hopes of success, the care of these lovely forms of vegetable life. We wish the author every success, and, in order to give some idea of his manner in dealing with his subject, extract the following:

About a mile from the town our road commences to skirt one side of the Dartington Wood on the right. The sun is shining brightly, but at this spot arching trees on each side of us envelope the path in dark shadows. A little distance further on, we reach a point in the road where a rushing stream comes out of and flows for some distance by the side of the wood. The scenery at this spot is beautiful almost beyond description. All who admire sylvan loveliness should visit it.

* “The Fern Paradise,” By G. Heath. London: Hodder & Stoughton.

A rude rustic bridge crosses the stream and gives access to a narrow, steep, and winding path which leads up into the dusky recesses of the wood. When we travelled the route we are describing, it was May. On the right of the rustic bridge, and almost overshadowing it, a large Hawthorn bush was white with blossom, and scented the air all around with its delicious fragrance. Below us the stream was rapidly eddying, waving the weeds and wild growth that sprung up from its bed. Just in front, a sudden fall in the level of the stream caused the gurgle and foamy splash of a tiny waterfall. A sloping bank led down on the right from the road to the water’s surface, covered—in such splendid luxuriance as is everywhere to be seen in Devonshire—with tall, rich, delightful green Grass intermingled with the dark green fronds of the Hart’s-tongue, and the handsome shuttlecock-shaped fronds of noble specimens of the Male Fern. The left banks of the brook hung far over the water, the bushes, Ivy, and Moss-covered branches of trees which crowned them affording cool, dark, and moist nooks for the Ferns, whose exquisite fronds, dropping gracefully over the stream in splendid clusters, lapped it with their beautiful tips. Beyond the bridge the stream flows for a short distance under the dark shadows of the wood, winding, falling, splashing, and foaming as it hurries along out of sight. The peep in this direction is delightful. Trees above—Moss-covered, Ivy-covered branches; some gnarled, and others fresh and vigorous; trees on each side, all densely clothed with their fresh and glorious May dress. The clear brook reflects the shadows of trees and shrubs, and becomes dimly seen as it disappears under the dark vista of the wood. This vista, formed of the delightfully intermingled branches of the trees overhead, presents the most charming peep. The matted branches, green limbs and twigs, would fairly exclude the light, were it not that at the darkest and densest part of the canopy slight openings afford a view of the sky, and whilst they admit the softened sun-rays, give the prospect of a beautiful wood-crowned hill, rising upwards beyond the delightful canopy, which hangs so gracefully over the clear and glancing waters of the brook. For some little distance the stream runs by the side of the road we are following, until, when the latter takes a sudden turn to the right, it disappears under a stone bridge, re-appearing for a brief space, and then being finally lost as it flows away across the meadows. Peer over the side of the bridge and you will find little tufts of that beautiful Fern, the common Maiden-hair Spleenwort; also the tiny Wall Rue, and small specimens of the Hart’s-tongue. You will rarely find a Devonshire bridge, unless it be quite a new structure, without its complement of Ferns—the rock, or stone-and-mortar-loving species. Whether it be a river bridge, or a tiny arch that crosses a brook, its sides are almost certain to possess at least one kind, often many, of the moisture-loving plants. No doubt it is the moist atmosphere produced by the flowing water underneath which gives encouragement to the Ferns. Sometimes a river arch is densely covered with many varieties of Ferns. You will often find the Polypody, the Hart’s-tongue, the Wall Rue, the Scaly Spleenwort, the common Maiden-hair Spleenwort, the Black Maiden-hair Spleenwort, growing together on bridge sides. But the specimens of Hart’s-tongue are invariably diminutive when growing on walls, rocks, or bridge arches. The Black Maiden-hair Spleenwort, unquestionably one of the most beautiful of the Fern family, is also usually found to be stunted when growing on the bare open side of a rock, wall, or bridge arch. It nevertheless delights in stones; but then the stones and rocks must be in the shade, and covered by overhanging bushes. A little way from the stone bridge already mentioned, on the road between Totnes and Ashburton, in the slate rock side of a hedge-bank, we caught sight of a tuft of the Black Maiden-hair, growing in a conspicuous position. We felt persuaded that other specimens would be near. One portion of the slate rock was hid by bushes that closed over it. Pressing these on one side, we found as we had expected an unusually fine plant of our Spleenwort, its roots being firmly embedded in the layers of slate rock, which were kept cool and moist by the shelter of the bushes. Where this Fern is to be found, you will always find the largest and most luxuriant specimens in the darkest and dampest corners. No Fern shuns the light more than the graceful and beautiful *Asplenium adiantum nigrum*. It is a great favourite of ours, and cannot, we think, fail to be admired by all Fern lovers. It is hardy, too, and will well repay in cultivation a very small amount of care and attention. It is astonishing how many delightful green lanes abut on to the high roads in Devonshire; lanes so temptingly beautiful that you feel you cannot pass without exploring them for, at least, some little distance. We espied such a lane when, on the road we are describing, we reached the top of the hill, on the other side of which lay Staverton Bridge. This lane turns out of the road on the right, and we explored it for a short distance. A few yards from the entrance, a bend in the lane hid its further course from view. But the peep just where it disappeared was charming.

THE PUBLIC PARKS AND GARDENS OF BRUSSELS.

AMONG European capitals of the second rank the pleasant city of Brussels stands pre-eminent. The lower town, with its Grande Place; the Hôtel de Ville, with its matchless spire; the many specimens of quaint mediæval architecture and the curious old fountains in its ancient streets, present many attractions to tourists; while the upper and more modern city, which contains the cathedral dedicated to St. Gudule, is remarkable for its Place Royale and Rue Royale, erected in a bold and striking style of architecture, dating from the first half of the eighteenth century—a style which has an artistic physiognomy of its own, and which is distinguished throughout the low countries as the “style de Bruxelles.” The “Park,” as it is termed, was created about the same period, and in its style and arrangement bears a strong resemblance, on a small scale, both to Versailles and the Tuileries. It is laid out on a generally geometrical plan, but portions have been left to a certain extent wild, with untrained timber trees, in a somewhat similar manner to the northern side of Kensington Gardens,

round which is a broad circular walk. One of these shallow basins is a dry one, floored with turf; the other contains a handsome fountain, and the water teems with gold and silver fish. The vista is closed to the north (beyond the boundaries of the park), by the handsome building containing the Chambers of Peers and Deputies, and to the south by the Royal Palace, which has recently been rebuilt in a somewhat sumptuous fashion. This charming little “park”—for, in spite of certain topiary formalities, it is exceedingly attractive—is not much larger than Lincoln’s-inn Fields, and yet it has its casino, and its theatre, both partially concealed among the trees of the northern extremity;—showing how very much more might be done with the open spaces in and about London than is at present attempted, or even dreamed of. While making this remark, it is by no means intended to recommend that more should be attempted than the space at command legitimately admits of, as has certainly been the case with Leicester Square, which is, nevertheless, an advance in the right direction. Brussels possesses a second park, of very distinct character,

View in the Public Park at Brussels.

the plantations of which were laid out about the same time. Two of the untrimmed portions of this graceful little “park” form deep valleys, in which deer were formerly kept; and fifty years ago nightingales visited these shelters in early spring, their lavish carollings being heard as far as the Place Royale and even in the Montagne de la Cœur. In those days the ancient fortifications still existed, the high ramparts having only one row of houses between them and the park, and beyond the walls was open country as far as the great forest of Soignies, the massive foliage of which, skirting the horizon for many leagues, was visible from the eastern ramparts. The demolition of the fortifications, and the creation of vast new streets and suburbs in that direction, has driven the nightingales as well as the picturesque hoopoe and the golden auriole away from the “park.” Our engraving represents the main avenue of the park, bordered with statuary, some of which are of a superior character. The line of this principal walk is interrupted and pleasingly varied by two handsome shallow basins, surrounded by a fine marble coping,

at a distance of some three or four miles from the heart of the city, beyond the Namur suburb. This is the wood of La Cambre, the Bois de Boulogne of modern Brussels. Immediately after the levelling of the old ramparts, long lines of houses of a superior character sprang into existence with such rapidity, along the principal roads, that the first portion of the forest-land, by the Chaussée de Namur, was reached by the builders in an incredibly short space of time; and the first outlying strip of forest, the Bois de la Cambre, would inevitably have been laid low, and bricks and mortar have taken possession of its groves and slopes, to convert them into prosaic streets, had not the Government stepped in, and secured it for the State. It is a very picturesque piece of wild woodland; and care has been taken, in converting it into a promenade for the recreation of the citizens of Brussels, to preserve its wild character as completely as possible. In spring its steep slopes are covered with early wild flowers, and the nightingales and other song birds fill the old trees with a cheery concert each morning and

evening. It is a favourite Sunday promenade; and, indeed, hundreds of carriages may be seen rolling gaily along the Chaussée de Namur almost every fine afternoon for drives in the Bois; the ancient promenade, the celebrated Allée verte, along the side of the great canal, near the Porte de Laeken, having been partially destroyed in consequence of important improvements and alterations. The only feature which art has added to the Bois de la Cambre is a very grand archway, formed of characteristically executed rock-work, of fine naturalistic aspect. It serves as a viaduct for the completion of a carriage road round the outer limit of the wood, and has a very fine effect. A footway passes underneath it in the direction of one of the entrances. Brussels possesses two other promenades; one, the new botanic gardens, occupying a portion of the ancient fosse of the fortifications, and the other the zoological gardens, which last is important, both on account of its dimensions, and also on account of the skilful manner in which it has been laid out so as to combine landscape effects with the exhibition of animals—large spaces being allotted to some kinds, such as deer and antelopes, rare species of exotic cattle, aquatic birds, &c., which there appear almost as though seen in their natural state. The space being, or appearing much more extensive than that of the Zoological Gardens in the Regent's Park, spacious and picturesque arrangements of the kind referred to have been much more easily devised. Many of the points of view in these gardens are extremely beautiful; and, in the planting, many new or rare trees have been selected, which impart a greater freshness of aspect to the scene than if the old familiar kinds, however beautiful, had been alone resorted to. The refreshment rooms form a spacious building of handsome elevation, and are much resorted to in summer for dinner parties, suitable accommodation for which being very complete. In the attached pleasure garden are large kiosks, in which good music may be heard on most summer afternoons; in the evening they are often let to different choral societies, and, when illuminated on such occasions, these extensive zoological and pleasure gardens form a pleasant lounge, which can scarcely be surpassed by any public garden in Europe.

Change of Climate in Scotland.—Mr. Buchan lately read a paper before the Edinburgh Botanical Society on the "Bearing of Meteorological Records on supposed Change of Climate in Scotland." He referred to the deep-rooted opinion generally entertained that the climate of this country has changed, and then showed a number of meteorological charts prepared from observations taken at Gordon Castle, Edinburgh, Dollar, and Dunfermline, extending from 1780 to 1870, which proved that during this period there had been no permanent alteration of climate. His general conclusion was that, while there were fluctuations from year to year in the temperature of particular months, there was no such general falling off in summer heat or diminution of winter cold, as had been suggested by Mr. M'Nab, to account for certain phenomena of vegetation. Taking December, he found twelve years, commencing from 1782, in which that month was above the average of temperature; then twenty years, in which it was greatly below the average; then nearly a quarter of a century, in which it did not come down to the average; then fifteen years, in which it was generally under the average; then five years, in which it was above the average; then the last five or six years, in which it had been a cold month. Similar fluctuations were observable in January and November. Taking July again, he began with a warm period; then there was a cold period of nearly the same extent as the December cold period, but not so pronounced; then a period slightly above the average; then one below the average, and so on—the last six years having had warm Julys. There was here, then, the same fluctuation, but no permanent reductions of heat. As a statistician, he should say that before any positive opinion could be pronounced as to a permanent change having passed on our climate, they must have the averages of at least a thousand years. Mr. Buchan went on to suggest that while there might be no excess or defect of temperature on an average, in recent years as compared with the past, alterations might occur with greater frequency and intensity, and occasion an amount of mischief which was not due to general defect. He quoted figures showing the number of times that certain stages were reached in different periods; and in conclusion, submitted that the prevalence of intense cold or heat was quite local, and that when there was great cold in one place, there was great heat contiguous to it.

THE FRUIT GARDEN.

GOOD VARIETIES OF PEACHES.

Tullins, or Syrian Peach, also called Michal's Peach *Pêche de Tullins, Pêche Michal, or Pêche de Syrie* (French).—This little-known variety is among the fruits recommended by the French Pomological Congress, and it is also included in the list given by Messrs. Decaisne and Naudin in the fourth volume of their "*Manuel de l'Amateur des Jardins*." Mr. Chatin speaks of it in the "*Journal de la Société Centrale d'Horticulture de France*," as a handsome and good free-stone variety, which thrives well as a standard on the hills along the valley of the Isère; but in the climate of Paris it must be grown as an espalier, or against a wall. It has borne the third year from seed. The introduction into France of this excellent Peach is due to Commander Barral, who brought a small bag of the stones with him on his return from Egypt, and presented them to Dr. Michal, of Tullings, as being more precious than a bag of gold. Until within the last few years its cultivation was almost limited to the commune of Tullings.

Alexis Lepere.—This variety was first submitted to the Comité d'Arboriculture for their judgment in 1871; and each year since it has been again presented for further test. It is of good size, and the colouring is very attractive and beautiful. The flesh is of fine grain, melting, juicy, sugary, and agreeably perfumed; thus uniting all the qualities requisite to entitle it to the qualification of excellent. It was raised from seed by Mr. Alexis Lepère, junior, in Germany, who has dedicated it to his father. The stock has been entrusted to Mr. Columbier, nurseryman at Vitry, who will send it out.

Salway.—This Peach, which is now very little grown in this country, has the name of being the best late variety, or rather the latest of good varieties, on the Continent. What, however, is far more strange, it is quoted among the novelties in fruit trees. It is recommended not alone for its lateness, but also for its flavour, which is probably heightened by a Continental autumn.

Early Beatrice.—This, and some other varieties raised by Mr. Rivers, are making their way on the Continent, and are favourably mentioned by French pomologists. Well ripened fruit of a good colour of this variety was exhibited before the Central Horticultural Society of France, on the 9th of July last year, by Mr. Chevalier, of Montreuil, and the Fruit Committee recommended it for trial. This variety appears to have a brilliant future before it.

Early Rivers.—This also was submitted to the same Society, by Mr. Jamin, on the 23rd of July, and was likewise approved.

It is gratifying to find that our only raiser of note has been so successful, and the opinions of Continental growers will have some weight with British gardeners.

H.

SHADING PINES.

YOUR correspondent, Mr. Barnes, comes down with a sweeping condemnation of this practice; but, although I do not, as a rule, advocate it, yet in some cases, and under certain circumstances, it may be desirable and even necessary. Much depends on the kind of structure Pines are grown in, whether lean-to, or span, or constructed of iron or wood. It may be that Mr. Barnes has had more to do with lean-to heavily-timbered houses, in which case shading would be unnecessary. Many of the modern houses, although well adapted for winter work, admit such a flood of light and sunshine as to render shade absolutely necessary for a few hours daily during the early summer months, as, without it, so much air is required to keep down the temperature, that every particle of moisture is taken out of the atmosphere, and vegetation, of whatever kind, suffers accordingly. The aspect of the house will have much more to do in determining the question of shading than the structure itself, and the kind of glass it is glazed with is of more importance than either. Common sheet-glass is often very wavy, and with numerous lenses, and, unless a thin shade is applied, plants suffer very materially under it. I have long since observed that houses tolerably woody are preferable in every way for all purposes during the summer months to those built very light, with wide sash-bars, &c. The former afford just sufficient shade of a natural kind, that shifts as the day advances, and acts in this respect much in the same way as the numerous leaves of a tree in shading each other. It is an easy matter to have houses too light and sunny; I have seen some where it was even found necessary to shade the Vines that they contained, and the treatment they received evidently suited them, for I never saw leaves that were larger, or of better quality. In very light houses, evaporation goes on at a very rapid rate, and no doubt many of your readers have observed the poverty-stricken appearance of vegetation under such structures. To have health and free growth, there must be moisture in the atmosphere proportionate to the amount of light and sun admitted; if not, the plants soon present a starved appearance, and

become a prey to all kinds of insect pests. If it were possible to have the greater portion of the inner surface of houses covered with water, the atmosphere might be kept in a healthy growing condition, and shading would then be unnecessary; but the amount of sunlight to be admitted must at all times be regulated by the quantity of moisture that can be given off to counteract the rapid evaporation that is always going on under bright sunshine so long as air continues to be admitted. Judgment in this matter of shading, doubtless, is necessary, and experience only can teach where and under what circumstances to apply it. I note that your correspondent partly admits the necessity of shading during very hot days, as he says, on such occasions, the lights may be tilted so as to reduce the force of the sun's rays; but, then, there are many houses so built as to render this mode of airing and shading impracticable, and recourse must then be had to other means. Mr. Barnes's well-known success as a Pine grower entitles him to speak with authority on such matters, and it may appear somewhat presumptuous on my part to call in question anything he says on the subject; but I think he may see reason to modify his sweeping assertion that shade is altogether unnecessary, and even injurious, to the healthy growth of Pines. I object to permanent shade as strongly as anyone, and the moment the air is taken off, the greater the amount of sun and light that can be admitted the better, provided it is accompanied by the necessary amount of moisture, as it is the sun's warmth and light that build up and solidify the different organisms of plant life. J. SHEPPARD.

GRAFTING VINES.

THE effect of grafting Vines on various stocks is an interesting subject to most cultivators of the Grape. Having had some experience in the matter, I cannot help thinking too much is expected in the way of permanent advantages from grafting one kind of Vine on another. As a nurseryman, the whole subject of grafting has always appeared to me most curious and interesting, and some of its effects most difficult to explain. Why should one require two or three kinds of Plums to work Peaches and Nectarines upon? Can anyone guess even why a Royal George and a Grosse Mignonne will not both grow on the same kind of Plum? Why should Joséphine de Malines Pear grow freely on a common White Thorn, whilst most Pears refuse to grow on it? Why should many Pears grow freely on the Quince, whilst others will not live, or become stunted and unhealthy? Of those Pears which do grow freely on the Quince, why should the fruit of some—for instance, Louise Bonne—be improved in every way, particularly in colour, being of a fine red and yellow, when the same Pear in the same garden, growing on a Pear stock, is perhaps a dull red and green? All these are interesting subjects of enquiry, and not easy to answer; but no one will deny that, as facts, they have a practical bearing on cultivation. But, in the cases hinted at, the effect of grafting a plant on a totally different though allied kind of plant is in question; in the case of Vine-grafting it is the effect of one Vine-root on another Vine-stem and fruit. There appears to me a good deal of difference in the two cases. My own opinion is, that in a few years a Vine-root will be what the top has made it. When a young man I frequently acted as my father's foreman, and superintended the execution of orders for fruit trees. I soon found that certain Apples, Pears, and Plums had, as a rule, better roots than other kinds standing close to them, worked the same year and on the same kind of stock. The effect of the top on the root in these cases I could not doubt. Now take the case of the Vine, say a delicate weak-rooted kind, grafted on a Black Hamburg—will it continue to make as much root and the same kind of root as the Black Hamburg would have done? But this is theory; let us come to observed facts. One of my favourite Grapes is Muscat Hamburg. It always has done well with me, however grown; but many years since, finding many persons complaining of it as tender-rooted, I tried the effect of grafting it on other kinds, and was soon quite convinced it was much improved by grafting on the Black Hamburg. To my surprise, the foliage was not only stronger-looking, but slightly altered in shape; whilst the branches looked more Hamburg-shaped, and the berries were very decidedly rounder. Another Muscat Hamburg grafted on a Sartelle Frontignac was as much altered in the contrary direction—the leaves being more cut, the branches longer and thinner, and the berries more oval, than on the original plant growing on its own roots. But each year these effects were less and less apparent, and I have now two Muscat Hamburgs growing on Black Hamburgs, which no one could tell were grafted. Some years since, I saw a Vine of this variety growing in the large house at Chiswick so entirely altered in foliage, fruit, and even flavour, by grafting on a late Spanish Grape, which looked like a bad variety of Barbarossa, that I would defy anyone to have identified it; and if Mr. Barron had not assured several of us that he grafted it himself, we never should have

believed it to be a Muscat Hamburg. But Mr. Barron told me lately it had altered and improved every year, till it resembles its parent. Having sold more grafted Vines, perhaps, than all the trade put together, I still am constrained to believe the effect of grafting is but temporary, and, whether for good or evil, will disappear in four years at farthest. Even if such be the case, it does not follow that it is not worth while to give a fine Grape, thought to be a little tender, a better chance of a good start in life by placing it on a vigorous root to begin with.

J. R. PEARSON, in the "Gardener."

Dew-like Drops on Grape Leaves.—Where I now write there are three Vineries, each of which contains plants of the Frankenthal and common black Hamburg. In one of these houses—and, curiously enough, in only one—I have observed an abnormal condition of the Grapes which is very remarkable. Every morning, the Vines, especially the tips of each lobe of the leaf, are covered with moisture that bears some resemblance to heavy drops of dew; and I, at all events, am unable to give any certain explanation of the cause of the phenomenon. Possibly it may be traced to the fact, as yet unascertained, that the roots have penetrated the soil too deeply, and that an extra quantity of sap is forced through the tissues of the plant. Whatever may be the cause, however, the effect has been that on hot days, when the rods have not been tapped to shake off the accumulation, the leaves in many places have been scorched.—S.

Root Pruning to induce Fruit-Bearing Superseded.—Some fifteen years ago, writes a correspondent of the "American Agriculturist," I had a small Apple tree that leaned considerably. I drove a stake by it, tied a string to a limb, and fastened it to the stake. The next year that limb blossomed fully, and not another blossom appeared on the tree. Therefore, after thinking the matter over, I came to the conclusion that the string was so tight that it prevented the sap returning to the roots; consequently, fruit buds were formed. Having a couple of Pear trees that were large enough to bear, but which had never blossomed, I took a piece of coarse twine and wound it several times around the tree above the lower limbs, and tied it as tightly as I could. The next spring all the top above the cord blossomed as white as a sheet, and there was not one blossom below where the cord was tied. A neighbour, seeing my trees loaded with Pears, used this method with the same result. I have since tried the experiment on several trees with almost equal success. I think it is a much better plan than root-pruning. In early summer, say June and July, wind a piece of strong twine several times round the tree, or single limb, and tie it, the tighter the better, and you will be pleased with the result. Next winter or spring the cord may be taken off.

Tap Roots of Fruit Trees.—I bought an Apple orchard for the sake of the gravel underneath it. The trees were large, and probably fifty to seventy-five years old; and the ground was sand or fine gravel, very porous and very subject to drought. I removed the earth, beginning at the foot of the slope, and running a trench 10 to 15 feet beneath the trees. I found an abundance of roots running as usual near the surface, and in addition I found a large number, perhaps one-sixth of the whole, running perpendicularly the shortest cut to the wet ground at the bottom of our digging. They started, some from the body of the tree, and others from some of the main roots—having few or no branches until they reached the wet soil, where they had a multitude of short fibrous roots, having the appearance of a broom, and wholly unlike the horizontal roots in that respect. To my mind, these tap roots explained the reason why the orchard had not perished from drought years ago. I think that water was what they were after, and that alone. Otherwise, they would have had side branches on their way down, and their rootlets at the bottom would have spread farther. I have since removed some Apple trees that stood on land that seldom, if ever, suffers from drought, and they had no tap roots.—"Cultivator."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Prolific Currant of Palluan (Fertile de Palluan of the French).—This variety has very long branches, and medium-sized red berries, similar to those of the ordinary Large Red, though perhaps scarcely of so agreeable a flavour; but, in fertility, it is surpassed by no variety, being a most abundant bearer. It is also a very free grower.—W. B.

The Cherry Currant (Groseille cerise of the French).—This is the largest of the Red Currants. The branches are short and few-berried; the berries very large, with a deep red skin; flavour acidulated. It is an early and good variety, though on the Continent, on the authority of Mr. Pynaert, it is not considered of first-rate quality in regard to flavour; but, being of much finer appearance than the common Red Dutch, it supersedes that in the markets. It is exceedingly prolific, and of vigorous constitution.—H.

TREES AND SHRUBS.

ORNAMENTAL TREES.

In planting for effect the habit of the trees employed is of the first consideration. Next to the general design, there is nothing which so much affects the appearance of a park, for instance, as the form of the trees that adorn its surface. Perhaps no tree that has grown up naturally can be called ugly; but I do not suppose anyone would think of comparing, for ornamental purposes at least, a shapely umbrageous Beech or Sycamore, with its far-spreading branches and symmetrical head, with a bare-limbed specimen of the same class. For planting in masses no species come amiss, but for single specimens for dotting the landscape suitable varieties are not so numerous. Much depends, however, on soil and situation. No trees will grow in a shapely form without room and light; nor will they be likely to withstand the hurricane unless they have reared their heads fully exposed to its force from their infancy. Hence, in parks which have been extended by clearing away the timber there is often great ruin worked among the trees that have been left, whether singly or in groups. Not far from where I write, a clump of Beeches—none of the specimens single—which was left in this way years ago to conceal a building, has been thinned out every year by one or other of its members yielding to the storm, and now but few of them are left. Thinning-out should, therefore, always be performed with great care when the trees are left with an eye to effect, and the species should be considered. The Oak will perhaps bear isolation after being “nursed” better than any; so will the Ash, though rather an ungainly tree by itself, but tall. The Elm is a somewhat dangerous tree, and so is the Lime; though one of the handsomest-shaped trees of the forest, it is often split in two at the trunk, or is apt to lose an important limb; but, when reared in the open, it is safe enough. The Horse Chestnut is a universal favourite, and forms a noble head. The Sycamore, though the foliage and smaller branches frequently suffer from the wind, presents a stout front to the storm, considering its heavy masses of foliage. The Spanish Chestnut, though of lofty bearing and luxuriant leafage, is one of the best to keep its place. In a very windy district, where it was one of the latest trees, I have seldom seen it suffer seriously when other trees were sadly mutilated. For planting to grow into specimen deciduous trees, the Lime is, I think, the one which assumes the handsomest form. A uniform and somewhat round head is its general habit, but in some situations it forms a perfect cone. In the parks about Clumber are to be seen some of the most perfect specimens of this kind. There is one tree in particular which attracts attention, not far from the Workop Road. The trunk is about 6 feet high, the head a cone, absolutely perfect in its symmetry. It could not have been clipped into more perfect shape, and, had it been in a garden, anyone might have concluded that it had been formed by the shears. It is not the only symmetrical specimen, however, of the same kind in the locality. The shape of this tree seems to be affected by the character of the soil in which it grows. It has always a very branching habit; but, in finely-divided sandy soils, the branches appear to be more twiggy and sub-divided, which helps to give the head a symmetrical shape. In heavy soils, owing to disproportion in the size of the limbs and branches, the tree is not so shapely. In both cases most likely the character of the branches indicates the character of the roots, which are no doubt influenced by the soil. Next to the Lime comes the Beech, which in the open park forms an even round head, the diameter keeping pace with the height. When cattle graze amongst the trees, they keep the branches trimmed as far as they can reach from the ground, and help to keep the trees in shape. This tree, with the Horse Chestnut and the Oak, lend a distinct character to the landscape, and are generally associated with rich meadow land and a soft undulating country, as the Fir is with the mountain slopes and Alpine ranges. How totally changed the appearance of the landscape may be by the character of the trees with which it is furnished must be apparent to the most casual observer. A few groups or rows of Poplars, rearing their tall spires against the sky, create a distinct impression on the scene; while a sky line of distant Firs, with their motionless pyramidal forms towering one above another, completely alter its aspect. The sombre Scotch Fir, too, almost darkens the face of the landscape with its sable plumes and dark masses of foliage, which throw the shining bark of its trunk and limbs into bold relief. The Firs, however, are most effective in masses or groups when a distinct effect has to be produced; single specimens are lost, unless it be on a lawn, where they are ornamental enough. The Cedar of Lebanon is of course an exception, from its unique yet ornamental habit, which associates pleasingly with some forms of architecture. Weeping trees of most kinds must be included in the handsome class, but they associate best with dressed

grounds, their branches often trailing on the surface of the lawn. Amongst these the Weeping Ash must be reckoned as one of the most ornamental, from the length of its branches and the freedom of their sweep. For grace there are none second to the Birch and the Beech. The Elm looks well on a tall stem, but when worked near the ground it has rather a stiff appearance, though such trees make excellent arbours, the branches being close and thickly covered with foliage. We have also a Weeping Pear and Thorn, the popular Weeping Willow, and Laburnum, the Weeping Lime—a noble tree—and others, all of them more or less ornamental, and adapted for pleasure grounds or parks.

J. S. W.

RAISING FEVER GUM TREES FROM SEED.

I am sending off to the River Gambia, West Coast of Africa, a quantity of the seed of *Eucalyptus globulus*, but the seedsman from whom I have bought it can give me no information as to sowing or the cultivation of the plant. Can any of your readers enlighten me on these points? If the tree possesses the disease-destroying qualities ascribed to it, its introduction into a colony so fatal to Europeans as the Gambia would be invaluable; I am therefore most anxious to make the experiment.—THOMAS C. CHOWN.

[We have no difficulty in raising the seeds of *Eucalyptus globulus* in this country, provided they are good. With a climate like the West Coast of Africa they should be sown in a northern aspect, that is, on the north side of a wall or close wooden paling, so as to keep the hot sun off them till they germinate, watering when necessary. After germination the young seedlings should be planted in rows, partially shaded, and watered. When they have become a little established, raise and plant them where they are ultimately to remain, and water freely at first. Some may be planted at once from the seed bed, where they are intended permanently to stand, provided they receive a temporary shading for a time with a close branch or large leaf, and are attended to with water till properly established. The *Eucalyptus* is not very particular as to soil. The ground in which seeds are sown should be well loosened, and not more than a quarter-of-an-inch of soil should be put over them, as the seeds are very small.—J. M'NAB.]

From the following account of the Fever Gum tree in California, as given in the “Horticulturist,” some additional information may perhaps be derived:—*Eucalypti* are rather numerous—there being not less than thirty species, of which the Blue Gum, or *Eucalyptus globulus*, ranks highest in public estimation. Of all trees, whether of this family or any other, it is the most rapid grower—besides possessing medicinal qualities which add much to its value. For a sparsely wooded region, where the temperature does not descend below 25° Fahr., no variety of tree can be grown to the same size in the same period of time. Its wood is useful for fuel as well as for manufacturing purposes. In raising this Gum tree from seeds, boxes should be made about 2 feet long by 16 inches wide, and from 3 to 4 inches deep, allowing small holes in the bottom for drainage. These should be filled up to within half-an-inch of the top with fine alluvial soil, moderately rich. The surface should be smoothed, the seed sprinkled evenly over it, and covered with an eighth of an inch of soil half composed of sand. To attain the best results the boxes should be placed in a cold frame. If sown in summer, the glass should be shaded. In the absence of glass, make a frame of boards with a moveable cover of laths nailed from one-quarter to half-an-inch apart, under which place the boxes. Water will be needed daily if the weather is warm and there is little moisture in the atmosphere, and should be applied with a fine-rosed pot. Seed treated in this way will germinate in from eight to fourteen days. When the plants are 2 inches high, begin to harden them off by allowing them more air, and increasing it from time to time until they have become hardy enough to withstand the heat of the day and the cool air at night. When 6 inches or more high they may be transplanted to a temporary or permanent place, according to circumstances. For forest culture, the young trees should be planted from 8 to 12 feet apart each way, and the intermediate spaces may be cultivated for two years, when the trees will be strong enough to take care of themselves.

Specimen Conifers at Bromesberrow Place, Gloucestershire.—The following, among others, occur at Bromesberrow Place, viz.:—*Cupressus macrocarpa*, the height of which when planted was 6 feet; after ten years' growth, 32 feet; and at the age of twenty-six years, 60 feet, with a circumference of 6 feet at the base. *Taxodium sempervirens*, the height of which when first planted was 3 feet; after ten years, 23 feet; after twenty-six years, 52 feet, with a girth of 8 feet at bottom. *Deodar*, height when planted 2 feet; after ten years, 25 feet; after twenty-six years, 48 feet, with a girth of 5 feet at the base. *Cedrus africana*, the height of which when planted was 18 inches; in ten years, 22 feet; and in twenty-six years, 48 feet, and four feet and a half in circumference at the base.—M. C. H.

A LABEL TRIAL.

I OBSERVE that some of your readers are interested in securing a good garden label for plants. A few years ago I made some in a variety of ways, using various materials for the purpose, and different sorts of ink. When finished, I fastened them to a board, which I nailed to a wall, fully exposed to all weathers. There were, in all, above 150 varieties; and I now send you two specimens which I took from the board last night, and which I consider have stood the test better than the others. You will perceive that they are made of zinc, and, as they were cut out by myself from the sheet, they were not expensive. No. 111, dated April 20, 1864, was first washed with muriatic acid to remove the grease, and then written upon; but in January, 1868, I tried fine emery-paper instead of muriatic acid, and you will perceive, by the label which I enclose, that it has stood well, and is very clear and legible. Some sheets of zinc are more apt to oxydise than others, and a little sweet oil rubbed over them when the ink is dry tends to correct this for outdoor labels; but, in a stove or hothouse, zinc has a still greater tendency to oxydise and turn white, and, if any of your readers can suggest a remedy for it, I shall be much obliged. The two labels to which I have alluded were written with an ink specially made for me by Mr. T. S. Flowers, chemist, now of Ryde, in the Isle of Wight; and my impression is that it stands better than any other ink which I have tried. You will see that I have adopted the plan of putting an eyelet into the label, similar to those used by shoemakers and others; for, as I always fasten my labels on Rose trees, &c., with copper-wire, the wire had a tendency to act injuriously upon the zinc, and the labels were sometimes cut through, and fell off; this, however, is obviated by the eyelet. I tried galvanised iron wire, but did not like it; for the thin covering of zinc cracks when twisted, thus leaving the iron exposed. I may mention that I adopt the plan, mentioned by your correspondent "J. G. N." (see p. 394) of punching Mr. London's mark into the zinc, but I write the names as well; and such labels, fastened on with copper-wire, are very permanent and inexpensive.

Hertfordshire.

C. B.

Cases of Precocious Flowering.—It is a common occurrence to find in seed beds flowers varying in shape, size, and colour, and others that differ much in the earliness or lateness of their times of blooming. In some instances these differences are very considerable. M. Carrière, writing in the "Revue Horticole," refers to some remarkable examples of this, furnished by a variety of Walnut (*Juglans regia* *preparturiens*) which sometimes produces nuts the second or third year after sowing, although the ordinary time for the fructification of trees of this kind is between ten and twelve years. Analogous peculiarities have lately been noticed both in the common *Ailantus* and in the *Weigela rosea*. Usually the *Ailantus*, like the Walnut, blooms when ten or twelve years old, and, until lately, no instance of its flowering before that period had been recorded. Last year, however, several specimens, only four months old, bloomed. As regards the *Weigela*, the blossoms showed nothing uncommon, but instead of failing to flower before the second year after sowing, more than 200 bloomed when four months old, and even earlier, one of the plants being only about 1½ inch high when this took place. M. Naudin, in a subsequent number of the "Revue," endorses the statement respecting this peculiarity in the *Ailantus*, and observes that the fact came within his knowledge fifteen years ago.

Alphonse Karr's Wistaria.—I leave my study at quarter before six: the sun is already high above the horizon; his rays sparkle like fire-dust through the leaves of the great Service trees, and shining on my house impart to it a rose and saffron-tinted hue. I go down three steps. Here we are in China! You stop me at my first word with a smile of disdain. My house is entirely covered by a Wistaria; the Wistaria is a creeping, branching plant, with a foliage somewhat resembling that of the Acacia, and from which hang numberless large bunches of flowers of a pale blue colour, which exhale the sweetest odour. This magnificent plant comes from China: perhaps you are admiring it there whilst I contemplate it here. I do not believe I exaggerate, even with you, when I declare that I think this a thousand times more beautiful than the richest palaces—this house of wood, all green, all blossoming, all perfumed, which every year increases in verdure, blossoms, and sweet odours.

Parks and Open Spaces.—The expenditure of the Metropolitan Board of Works on the parks and open spaces of London during 1874 has been as follows:—Finsbury Park, £2,750 1s. 6d.; Southwark Park, £1,818 14s. 3d.; Victoria Embankment Gardens, £792 19s. 11d.; Hampstead Heath, £521 15s. 4d.; Blackheath, £535 18s. 7d.; Hackney Commons (London Fields, &c.) £284 16s. 8d.; Shepherd's Bush, £86 2s. 9d.; Tooting Common, £90 12s. 2d.; Leicester Square, £256 0s. 8d. The total net cost was £7,137 1s. 9d.

SOCIETIES AND EXHIBITIONS.

MANCHESTER EXHIBITION.

MAY 14TH.

THE high character which the exhibitions held here have long and deservedly enjoyed was well upheld on this occasion, the display in some respects, notably that of Roses and Ferns, having seldom or never been equalled. Of Orchids there were hundreds, and, considering the earliness of the season, they were in magnificent condition. Those who are only accustomed to see the limited number of these plants shown now-a-days at the best of the Metropolitan exhibitions can scarcely realise the effect produced by the quantity and variety produced at the Old Trafford gatherings. The large exhibition building and annexe were completely filled with plants, and on the open ground surrounding the exhibition were to be seen everything conceivable in the shape of useful and ornamental appliances connected with gardening.

Stove and Greenhouse Plants (ten Flowering and ten Foliage).—In this class, Messrs. Cole & Sons, Withington, were first with a fine collection, conspicuous in which were *Azalea Duc de Nassau*, *Iveryana*, and *Conqueror*, and *Erica Lindleyana*, large and well-flowered. Among the foliage plants were remarkable examples of *Cocos Weddelliana*, *Phormium tenax variegatum*, *Cycas revoluta*, and a couple of good *Crotons*, viz., *pictum* and *variegatum*. Mr. Cypher, Cheltenham, who was second, had a remarkably well-flowered *Tremandra ericoides*, *Erica ventricosa coccinea minor*, *Genetyllis fuchsoides*, well bloomed and better coloured than usual, and *Clerodendron Balfourii*, fresh and finely flowered. Amongst his foliage plants were good specimens of *Croton Wisemanii* and *Gleichenia dichotoma*. Mr. Lingard, Bowdon, who was third, had a beautiful *E. ventricosa carnea*, *Hedera tulipifera*, *Allamanda grandiflora*, and a well-flowered *Anthurium Scherzerianum*; his best foliage plants were *Alocasia Lowii* and *Croton angustifolium*. Ten Stove and Greenhouse Plants in Flower.—In this class, Messrs. Cole were again first with a beautiful group of finely-flowered plants, amongst which were magnificent examples of *Hedera tulipifera*, large and profusely bloomed; the lovely *Boronia pinnata* in equally good condition; *Azalea Trotteriana*, a glowing mass of colour; the white *A. magnifica*, large and finely flowered; a grand *Erica aristata superba*—such a plant for size and quantity of flowers as is seldom seen. Mr. Cypher was second. In the amateurs' class of stove and greenhouse plants, Mr. Pilgrim, of Cheltenham, was first with a good collection, in which were *Anthurium Scherzerianum*, bearing sixty flowers of medium size; *Franciscea calycina*, well-bloomed and finely coloured; *Boronia pinnata* and *Pimelea spectabilis*, not so often seen as it was at one time. Mr. Thornber, Howick House, Preston, who was a good second, had a beautiful, although small, *Boronia serrulata*, *Hedera fuchsoides*, fresh and well-flowered; *Franciscea confertiflora* and *Statice profusa*. Mr. Stevenson, Lark Hill, who was third, had in his group two well-bloomed plants of *Aphelaxis*, one being an example of the large-flowered *A. macrantha rosea*, now a scarce plant.

Orchids.—These, as have been already stated, were shown in quantity and in fine condition. In the class of sixteen plants, Mr. Hubberstey, gardener to O. O. Wrigley, Esq., Bury, who was first, had large well-flowered plants, among which were splendid specimens of *Odontoglossum Phalaenopsis*, some 2½ feet across, literally loaded with lovely blossoms; *Masdevallia Harryana*, with twenty-four finely-expanded flowers, and some eight more to open; *M. Lindenii*, with an equal number of flowers; *Anguloa Clowesii*, bearing thirty clear yellow singular-looking blooms; a magnificent *Trichopilia tortilis*; *Odontoglossum vexillarium*, with ten fine flowers from a single bulb; *Cattleya Skinneri*, well bloomed, and good in colour; the old, but indispensable, *Calanthe veratrifolia*, bearing some twenty-four good spikes; and others equally meritorious. Mr. Mitchell, gardener to Dr. Ainsworth, who was a close second, had *Vanda suavis*, with six good spikes, and a darker variety of the same species, with four spikes; *Dendrobium Bensoniae*, well bloomed; *D. Wardianum*, large, but pale in colour; a fine *Cattleya Mossiae*; the beautiful *Laelia Brysiana*; and others all well flowered. Mr. Williams, gardener to J. Broom, Esq., was third. In the class of six Orchids, Mr. Hubberstey, was again first. Amongst other good plants in his collection were *Aërides roseum*, and a well-flowered *Masdevallia*. Mr. Goodall was second. In groups of three Orchids Mr. Hubberstey was first, and Mr. Williams second. Mr. Hubberstey also showed a beautifully-flowered moderate-sized *Odontoglossum Phalaenopsis* as a single specimen, for which he obtained a first prize. In the nurserymen's class of sixteen Orchids, Mr. B. S. Williams was first, with some good plants, remarkable among which were large well-flowered examples of *Cypripedium caudatum* and *C. barbatum superbum*; also of *Odontoglossum nebulosum*, and *O. luteo-purpureum*. In the class of ten Orchids, Mr. R. S. Yates was first, with a grand plant of *Aërides Fieldingii*, with three spikes of flowers, from 2 to 2 feet 6 inches in length; also, the Citron-scented *Odontoglossum* (*O. citrosmum*), with a dozen spikes of delicate blush-white flowers, and other good specimens. Among six Orchids, for which Mr. B. S. Williams was first, was a lovely *Dendrobium thyrsiflorum*, bearing a dozen fine spikes; *Odontoglossum sceptrum*; and a good *Cypripedium villosum*. In the class of single Orchids, Mr. B. S. Williams was also first.

Greenhouse Azaleas.—In this class, Messrs. Cole, who were first, had a fine specimen of *Cedo nulli*, a scarce, although old sort, but one of the most distinct in colour, and very effective. Mr. Stevenson showed in a group of six, for which he got a first prize, *Duc de Nassau*, a crimson sort. Mr. Potts, Manley Hall, who was second, had plants

a few days short of their best, but large and full of flower. Some fine Azaleas were also shown by Mr. Turner, of Slough.

Roses.—In the class of twelve, the competition was extremely close, and the plants, one and all, good. Mr. Turner, Slough, who was first, had Céline Forestier, Charles Lawson, Paul Verdier, and Madame de St. Joseph, all perfect examples of successful cultivation. Messrs. Paul & Sons, Cheshunt, who were second, showed grandly-flowered plants of Madame Victor Verdier, Juno, Princess Mary of Cambridge, and Céline Forestier. In the class of forty Roses in 9-inch pots Messrs. Paul & Son were also first, with a magnificent collection, furnished with very large flowers of every tint and colour, from the deep purple of Fisher Holmes to the delicate Madame Lacharme. Mr. Turner was second with a beautiful group, and Messrs. Lane, Berkhamstead, were third.

Eighty Alpine and Herbaceous Plants.—Of these, two beautiful groups were staged by Messrs. Rollisson & Sons, who were first; and Messrs. J. & W. Yates, who were second. These, set on the turf on slightly elevated ground, formed a charming feature, representing, as they did, almost every genus that can be had in flower at this season.

Ferns.—Amongst stove and greenhouse kinds the competition was so close that it was difficult to determine who was first; after close scrutiny, however, Mr. Thornber was awarded the first prize, for a group in which were three examples of *Gleichenia*, viz., *rupestris*, *Speluncæ*, and *flabellata*, each from 7 to 8 feet through, strong, and deep green—such plants, indeed, as could scarcely be elsewhere matched. Amongst tree Ferns in this collection was a fine specimen of the rare *Cyathea Dregei*. Mr. Hubberstey, who was second, had matchless plants of *Davallia Mooreana* (7 feet through, some of the fronds measuring 2 feet across), *Gleichenia flabellata*, the elegant *Nephrolepis davallioides* (8 feet across, a perfect fountain of drooping fronds), a good example of *Brainea insignis*, and some large and good tree Ferns. The first prize for hardy kinds was won by Mr. Thornber, whose plants were large, and in splendid condition; Mr. Handley, Prestwich, was second, with a group fine in every way; and Mr. Crowe was third with a beautiful collection.

Fine-foliaged Plants.—These were shown in large numbers and in beautiful condition. In the class of eight kinds, Mr. Elkin was placed first; but on what grounds we leave the judges to say. His best plants were *Cordyline indivisa* and *Latania borbonica*. Mr. Thornber, who was second, had a beautiful group, in which, amongst others, were *Gleichenia rupestris*, *Croton undulatum* (well furnished with finely-coloured leaves), *Cycas circinalis*, *C. revoluta*, and *Dasyllirion gracile*. Mr. J. Gresty, who was third, had a fine example of *Eurya latifolia variegata*, and *Cibotium regale*. Here, again, it may be added that the decision of the judges was not in any way satisfactory, the plants to which the first prize was awarded not being considered worthy of any prize at all. In the class of six fine-foliage plants, Mr. Williams was first, with a group in which were *Maranta Veitchii*, *Pandanus Veitchii*, and *Gleichenia semi-vestita*, all in excellent condition.

New and Rare Plants.—Of these Mr. Williams had a fine group, in which were *Æchmea Marie Regine* and *Adiantum gracillimum*. In Messrs. Rollisson's group, which was placed second, the most remarkable plants were *Croton Cooperii* and *Dracæna Baptistii*. Mr. Wills was third. Mr. Thornber, who was first in the amateurs' class, showed fine plants of *Martinezia erosa*, *Vriesia reticulata*, and *Dracæna Fraserii*.

Miscellaneous Subjects.—Of *Rhododendrons*, Mr. R. S. Yates showed a good bank of finely-flowered plants. Messrs. Standish & Co. also had a fine collection. Messrs. Cole, Yates, Pilgrim, and Smith showed some good Cape Heaths. *Ivies* (in pots) came from Mr. Turner, hardy evergreen trees and shrubs from Messrs. Caldwell and Messrs. Lane, succulents from Messrs. Rollisson, dinner-table plants from Mr. Thornber, Palms from Mr. Broom, Mr. Smith, and Mr. Yates; *Dracænas* from Mr. Wills, Messrs. Rollisson, and Mr. E. Boden; *Yuccas* from Messrs. Cole & Pavin, who had magnificent examples of *filamentosa variegata*, very large, and in splendid condition; and variegated Japanese plants came from Messrs. Standish. Bunches of cut flowers were furnished by Messrs. Cole, Yates, and Binns; wedding and ball-room bouquets by Mr. Yates and Messrs. Turner and Cypher. Mr. Bruce received an extra prize for remarkably well-grown *Sarracenias*, among which *S. rubra*, one of the scarcest plants in cultivation, was quite a model of good management. Mr. Williams and Mr. Wills each exhibited a large and fine group of miscellaneous plants, as did also Messrs. Dickson and Robinson. Hardy Conifers were shown by Messrs. Cardwell and Messrs. G. & W. Yates; and bronze and tricolor *Pelargoniums* by Mr. Gresty, whose plants were large and well-grown. In the nurserymen's class, Mr. Turner had a finely-coloured collection. Show *Pelargoniums* were shown by Mr. Rylance, whose plants were not extraordinarily large, but well flowered and good in foliage. Messrs. Jackman & Son contributed *Clematises*—magnificently flowered plants, amongst which were *Duke of Norfolk*, *Thos. Moore*, also several unnamed seedlings. Messrs. Standish also showed in the same class.

Double Furze.—Most people are acquainted with the single-blooming Gorse or Furze which is so abundant in many places as to be almost looked upon as being beneath notice from its very frequency. The double-flowering variety is, however, more valuable, and those who are in want of a showy yellow flowering shrub, worthy of the name, should try it. I have seen it in all sorts of positions, and in all it has a good appearance. It blooms, more or less, throughout the whole year, and the intensely yellow flowers are especially useful for distant effect. It thrives perfectly in any soil, from a pure, hot, dry sand, to the very best loam. Young plants of it, about a foot high, are best for planting, as, when of this size, they succeed better than when larger.—J. Muir.

NOTES AND QUESTIONS—VARIOUS.

New Support for *Tropæolum tricolorum*.—A piece of old fish netting fixed near the glass, at the end of a greenhouse, makes a capital support for this plant. I have had several square yards of it a mass of bloom, and the admiration of all who have seen it.—ALFRED PAGE, *Bulwell, Notts.*

A Fine Ginkgo Tree.—A few years ago I saw growing in the grounds of the Earl of Coventry, at Groom Court, a fine specimen of the Ginkgo, or Maiden-hair tree (*Salisburia adiantifolia*). As it was the largest I had ever met with, perhaps some of your correspondents will favour us with its dimensions.—B.

Camphor as a Fertiliser.—From time to time I have seen in the papers that camphor diluted in water is an admirable fertiliser. What proportion should be given to one gallon of water, and should I water the roots or foliage.—E. N. H. [We are not aware that there are any proofs of its effects in this way.]

Seedling *Mimuluses*.—We have sent a selection of our *Mimuluses* for your inspection and opinion of their relative merits.—E. G. HENDERSON & SON. [The flowers received were of large size, possessing bright and beautiful colours, and evidently belonging to a fine "strain" of these too much neglected, but really useful, plants.]

Cutting Back *Rhododendrons*.—What is the best time for cutting back *Rhododendrons* so as not to interfere with their flowering? Some of my large common *Rhododendrons*, which were growing too luxuriantly over the walks, and which had to be pruned back, and present now an unsightly front of cropped branches with no promise of flowers.—QUEBIST.

***Pinguicula vallisneriæfolia*.**—This is now producing its large and beautiful bluish-violet flowers with a whitish centre. The leaves of this species grow to a considerable length, sometimes from 6 to 9 inches. It is a plant which should be grown in very damp but well drained, and rather shady situations on rock-work.—R. P.

***Lithospermum Gastoni*.**—This is certainly one of the finest border plants with which I am acquainted, especially for a dry but deep soil. In the York Nurseries it forms perfect hillocks of bloom, the flowers being so closely packed as almost to conceal the foliage. The colour is a pleasing sky-blue.—R. P.

New Japanese Radish.—The new Japanese Radish or Daicon (*Raphanus* of French gardeners) has been tried in many French gardens with much the same result. All those who have grown it think it may prove very useful as a fodder plant, but hitherto it has gained little favour for the table. The same remark applies to a new Russian variety called Rave Garwoski.—H.

The Best Early Cabbages.—Amongst all the early varieties named in catalogues, I find none to come in before Downton Castle; on the 23rd of April I cut nine dozen. My next favourite sort is Pearson's Chilwell Conqueror, which we are now cutting in quantity. Both these sorts have the advantage of making Cabbages instead of leaves, and may, therefore, be planted much closer than the loose-growing varieties.—J. MILLER, *Clumber*.

Strawberries at Christmas.—Mr. Gilbert need not fear of success in having Strawberries at Christmas if he pots the different sorts of Strawberries in succession; keeping back will be his only difficulty. Mr. Jefferson, Carlton House, Worksop, is the best cultivator of late Strawberries with whom I am acquainted. I have known him to produce fine shelves of Strawberries from early-forced plants during the months of November and December.—J. MILLER, *Clumber*.

French Beans at Burghley.—I have heard of Potatoes that had to be cut in two before they could be got in at the door; Mr. Gilbert's French Beans must be related to these Potatoes. I find I can nearly cram the haulm of forty pots of French Beans, including the Beans, into a peck measure, but Mr. Gilbert gets a peck of Beans off forty plants at one gathering! Did his foreman climb up the Beans to gather them? Would Mr. Gilbert mind measuring one of these Beans, when he has time, and furnish us with the dimensions? I should also be glad of a few seeds by goods train.—CA. CANNY.

Cannas on Lawns.—I know nothing which has a more striking appearance on a lawn than a bed of Cannas. Their exotic-looking foliage seems to lend a special charm to the picture which a well-kept lawn, with properly disposed clumps, and good single varieties of Coniferous and other trees make up. Let them be only out of the fury of the wind, on an elevated bed, with a good border, such as *Stachys lanata* makes, and they form a fine feature. It is best to put a row of something inside the border or edge, as, say a row of Dell's crimson Beet; it hides the bareness of the stems of the Cannas at the bottom.—N. H. P.

The Mexican Mayflower.—We have received a flower of a very large and handsome variety of the Mexican Mayflower (*Lælia majalis*) from Mr. Hill, gardener to Sir Wm. Marriott, Down House, Blandford. The flower sent to us was fully 8 inches in diameter from tip to tip of the petals, the latter, as well as the sepals, being of a bright lilac or mauve tint, and crimped or frilled towards the edges. The lip is of ivory-whiteness, margined with rosy-lilac, and richly spotted with amethyst-purple. The crest is lemon-yellow, and the contrast of these delicate colours is very pleasing. This is one of the rarest and most beautiful of the New World Orchids, but is somewhat difficult to flower.

***Lilium Washingtonianum*.**—Messrs. Backhouse know too much about plants, both species and varieties, to write "*L. Washingtonianum*, new species," and it is to be regretted that Mr. Wilson should ascribe to them what they did not say. What they really wrote was:—"Lilium, new sp.? California. Allied to *L. Washingtonianum*; grows 6 to 10 feet high, and bears as many as forty flowers on the spikes, very fragrant. Regarded by the collector as either a distinct variety of *L. Washingtonianum* or a new species altogether." Mr. Wilson does not realise that *L. Washingtonianum* is a species and not a variety, or at least I gather so from his concluding remark at page 416.—WILLIAM BULL.

A North Wall Best for the Flame-flower.—*Tropæolum speciosum* does not do well on a south aspect. I find a north wall, sheltered from winds, to be most suitable for it; but it is such a rambler that it is difficult to keep it in its place. The stolons appear many feet, sometimes even yards, from the parent, which then sickens and dies. This may be from its having exhausted the elements of the soil essential to its well-being, as is the case with many other plants of similar character. The best way to treat it is to keep reserve plants by tracing back the suckers and potting them. Remove the old plant, replace the spent soil by a barrowful of light, rich, sandy compost, and then plant; the result will be strong growth and fine bloom; at least so I have found it. This should be repeated every three or four years.—J. M., *Hawkechurch, near Axminster, Devon*.

Frosted Glass for Screens.—This is made by laying the sheets horizontally and covering them with a strong solution of sulphate of zinc. The salt crystallises on drying.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

PLEASURE GROUNDS: THEIR EXTENT AND MAINTENANCE.

A PREVAILING error in English flower gardening is to attempt to keep too great an extent of ground in that order which is requisite in a dressed garden. I call it an attempt; for, in the majority of cases, it is nothing more; and this is so apparent as to exhibit nothing so distinctly as insufficient means, and consequent mismanagement. "A small farm well tilled, and a small house well filled," is an old maxim, the point of which may be applied with more force to the garden than any other department. Large flower gardens and pleasure grounds indifferently kept are not creditable adjuncts to a noble mansion; and, if this fact was more generally recognised, we should see fewer ill-kept gardens and better gardening. Practically speaking, a gentleman's pleasure grounds are not generally circumscribed by his ha-ha or his garden wall. He has his park and his woods; and, even if he desires his pleasure grounds proper to be extensive, there is no reason why he should not gratify his taste; but there should be no greater attempt at dressing and "keeping" than can be thoroughly done. If he desires acres of shrubbery and woodland, with pleasant walks and lawns, he may fitly combine the park with the garden, and yet secure that order and neatness which the character of the place suggests, and one naturally expects to see. One mistake is having too great an extent of flower-beds, with their intricacies of Grass or gravel walks, and Box or other edgings, which are so common. Where these are laid out and kept with taste, it alters the case; but what can be more slovenly in appearance than a great parade of floral decoration with an ill-kept lawn, lanky untrimmed edgings, and dirty walks? That this is no imaginary picture many will testify. A still more common mistake is in having too great an extent of closely-mown lawn. The fresh, green, and well-kept sward is certainly an indispensable and highly ornamental feature of our English pleasure grounds; but the labour it involves is great, and in nine cases out of ten some other important department suffers in consequence at the very time it requires the most attention. Keeping every foot of Grass in the grounds in "mowing machine order" is a practice for which there is no excuse. Besides, it precludes the possibility of growing many kinds of beautiful hardy plants, such as Primroses, Lilies, Daffodils, &c., that might otherwise have a place, for these cannot exist long where the lawn is mown regularly. Not long ago I saw, in the extensive pleasure-grounds of a nobleman, a blending, so to speak, of the garden and lawn with the woodland and the park, and with the most happy effect. In the garden front of a fine mansion—an imposing pile, which some landscape-gardeners would have considered incomplete without the usual terraces and parterres—there was nothing but a broad open expanse of well-kept lawn, thinly and irregularly dotted with ornamental trees and shrubs, with a few flower-beds and Roses in suitable situations near the mansion. Beyond the lawn, the ground rose into a natural thicket of trees and shrubs, with Gorse, tufts of Heath, Sweet Briars, Roses, Daffodils, and whole sheets of Primroses, Cowslips, natural Grasses, &c., in the foreground. Even Nettles and Docks were present; indeed, no "keeping" was attempted at all, unless it might be an occasional interference here and there, to prevent the law of natural selection from operating too decidedly in any one case. From this pleasant scene, which impressed me by its repose and the absence of glare, there wound towards the kitchen gardens, and other parts of the grounds, a broad well-kept walk, with wide margins of Grass on each side, having an irregular back line, and again the trees and shrubs rose up behind into a thicket in which the birds sang and built their nests in peace and security. The general effect was anything but untidy; the walks looked trimmer, and the Grass greener, contrasted with the rough natural coppice in the background. Throughout the extensive grounds, floral and other decorations were not forgotten,

but no more was attempted than could be done well, and it was not deemed essential to have a loud-toned display in front of the windows only and nowhere else. What was done in this case might be done anywhere, and under quite different circumstances. In very extensive pleasure grounds, where many acres of Grass, no part of which was in sight of the mansion, had to be regularly mown with the machine or scythe, and the outlines of the Rhododendron beds and shrubbery borders were pared and trimmed with the utmost exactness, at the expense of a neglected kitchen garden and hothouses, no better effect was produced, in my opinion, than if the undulating surface of the ground had been simply traversed with broad Grass paths, drives, or openings, and the rest left in a partial state of Nature, while the expense of keeping would have been reduced by two-thirds. I never was an admirer of formally laid out beds of Rhododendrons, or groups of single species of plants that had nothing more to recommend them than a blaze of colour for one month in the year, and played a comparatively useless part for the remaining eleven. Even a Rosary is a flat affair by itself, and to me an objectionable and utterly ineffective way of showing off the beauties of the queen of flowers, which never looks so well as when associated with other forms of vegetation. These remarks are made in the knowledge of the fact that the expense of gardening in these days of high wages has become a serious consideration to proprietors, and the difficulty has to be met by reducing the staff and working expenses—a course which has been pretty generally adopted within the last few years; hence the necessity of a change of tactics in garden management. Pleasure grounds are a luxury that must be paid for; but when such expensive structures as glass houses are neglected on their account, and cannot be utilised to the utmost for the want of labour and other means, it is a sheer waste of money; and the same applies to the kitchen garden. Market gardeners and nurserymen understand this, and the thorough manner in which their houses are employed might well be copied by private growers. To me it has often been a source of regret that the entire garden staff had to be employed two or three hours at least every day, from April till November, cutting Grass, which afterwards required the whole day's labour of several men to clear up, and attend to the consequent clipping, hoeing, and trimming which it occasioned; while fruit trees and crops had to go uncared for, and many things of real interest or utility were neglected. C.

Cutting Back Rhododendrons.—Allow me to recommend "Querist" (see p. 436) to cut his Rhododendrons back immediately they have done blooming. For that operation there cannot possibly be a better time, and, if cut back into the old wood, they will break freely.—JOHN WATERER, *Bagshot*.

— "Querist" should cut his Rhododendrons back in the winter by partial pruning, viz., cutting back some of the longest branches only to their base, and thus reduce the outline of the plant 2 or 3 feet. He would then have a fair amount of bloom, more or less in proportion as he thinned the plant, and it would still have the appearance of a naturally-grown plant. By annual prunings, he may reduce it to any size he wishes. The plants would now be starting freely and thickly, and a common observer would not know they had been touched. Large clumps here, pruned in this way, are no larger than they were twenty years ago.—JOHN GARLAND, *Killerton, Exeter*.

The Flame Nasturtium among Rhododendrons.—Twelve or fourteen years ago, I planted this among and near the margin of large masses of Rhododendrons, and each year it grows up among them most luxuriantly about 8 feet high, flowers beautifully, and is much admired. The natural soil is a rich light loam. The choice kinds of Rhododendron are planted in peat. This plant does as well on the sunny as on the more shaded side of borders.—JOHN GARLAND, *Killerton, Exeter*.

Privet Hedge Grafted with Lilac.—It would be useful information if anyone would give us a list of shrubs that might be grafted on Privet, or Thorn, or other hedge material. I have Pears growing and fruiting on a Quick hedge. On a Privet hedge here I grafted Lilacs at certain distances apart, in order to break its monotonous and formal appearance, thus rendering it more ornamental. The Privet was formed into a series of scollops several years since, and no difficulty exists in maintaining the desired shape. On the crest of each curve Lilac was grafted, a convenient shoot from the Privet being selected on which to place it; this has continued to grow and bloom with considerable vigour, and is a very pleasing feature in the garden.—W. INGRAM, *Belvoir*.

Plants in Flower at York.—The following choice plants, some of them new, are now finely in bloom in Messrs. Backhouse's nursery at York, viz.:—*Cypripedium arietinum*, *C. Calceolus*, *C. macranthum*, *C. pubescens*, *Dianthus glacialis*, *D. Fischeri*, *D. alpinus*, *D. neglectus*, *Mertensia alpina*, *M. sibirica*, *Primula Parryi*, *Edraianthus Kitaibelii*, *E. pumilio*, *E. pumilorum*, *E. serpyllifolius*, *Aquilegia glandulosa*, *Petrocoptis Lagasce*, *Rosa alpina* var. *pyrenaica*, *Polygala calcarea*, *Lewisia rediviva*, *Eritrichium nanum*, *Pentstemon humilis*, *P. acuminatus*, *Cyclobothra pulchella*, and *Cypripedium acaule*. The English *Cypripedium* (*Calceolus*) is flowering in great groups of thirty flowers in each, twice the size of the ordinary ones, and many have two flowers on one stem. There is also a grand Siberian species now in flower, a rich crimson, called *macranthum*.—NOEL HUMPHREYS.

NOTES OF THE WEEK.

— THERE is now a long and stately fringe of the Royal Fern pushing vigorously up beside the water under the tree near the lower end of the Serpentine. This addition is one of the happiest that has been made to the permanent attractions of the public gardens of London.

— GOOD French Cherries have been abundant in the London markets during the past week. They are grown about Avignon, and in the adjoining districts.

— THE curious Californian *Saxifraga peltata* or Umbrella plant is now in flower at Kew, where it may be seen in the herbaceous department. The plant is a native of the woody region of the Sierra Nevada, where we have met with it in company with the fine Lilies that are now becoming such favourites with cultivators.

— A SPECIAL exhibition of Roses is to be held in Lyons on the 11th, 12th, and 13th of next month. The judges are to consist of English, German, Belgian, Italian, Swiss, and French Rosarians. Several seedling Roses will be shown on that occasion for the first time, and English Rosarians are invited to send theirs.

— THE Maryland Peach growers anticipate an unusually heavy crop, the lateness of the spring having delayed the opening of the buds, so that they did not suffer from the April frosts. The art of canning the fruit is now so perfect that the state of the crop in the great Peach region of the eastern United States is of interest to all the world.

— AN enumeration has just been made of the number of trees planted during the past season in the avenues and boulevards of Paris to replace such as have died, and the total is found to be 178,000.

— THE long "flower walk" in Kensington Gardens is, so far as its trees and shrubs are concerned, interesting and beautiful for a considerable portion of the year; and we should like to see it made more so as regards perennial and Alpine plants. It offers the finest opportunity that could be desired for the formation of a "mixed border" of the best kind. The mixture of "bedding-out plants" and other subjects, dotted at regular intervals all along the border, which has for many years been the rule here, is not the most desirable. The aim should rather be to give each twenty yards' length of the border an aspect of its own. This need not prevent a good many individuals of any favourite kind from being planted when desired.

— THE Royal Botanic Society's Evening Fête will be held on Wednesday, July 14th, on which occasion prizes will be offered for various kinds of table decorations, and for bouquets, hanging-baskets, &c., and for groups of plants arranged for effect. The gardens are even more than usually enjoyable this year, notwithstanding their disfigurement by various contrivances, placed in conspicuous positions, to assist in the taking of meteorological observations. It is laudable in the Society to take so much interest in so important a branch of knowledge; but that is no reason why the best example of landscape-gardening art to be seen in any public garden in or near London, should be disfigured by such nondescript abominations as that which now crests the top of the mound on the right, as the visitor enters the garden from the front gate.

— A SPECIAL meeting of the Fellows of the Royal Horticultural Society was held, on Tuesday last, to receive a communication from the Council, and an answer to certain proposals made by the Council to her Majesty's Commissioners. Lord Bury, who presided, said that a reply had not yet come to hand from her Majesty's Commissioners, but he hoped it would come in the course of the next ten days, and he moved an adjournment for that period. He then referred to the fact that actions in the county court were being taken against the Society by gardeners who had won prizes last year and had not yet been paid. If those proceedings went against the Society, the Council would file a declaration of insolvency to protect their other creditors. This statement of the President gave rise to a long and excited discussion, in which Mr. W. A. Lindsay (late hon. secretary), Dr. Kellock (member of Council), Sir A. Gordon, and Mr. Guedalla took part, it being strongly urged, by some of the speakers, that the prize-money due to exhibitors should be paid. Mr. Dobree (treasurer to the Society) said they had at their bankers about £2,000, and, if he paid these prizemen the £1,400 due to them, the Society must come to a standstill. He objected to sign any cheques to pay the prize-holders. Dr. Denny asked what was to become of the show to come off on Wednesday, the 2nd of June? Would it not be better to close the gates of the gardens than to take 7s. 6d. for admission? The chairman replied that on the last occasion they considered the show was not sufficiently good to warrant the prices demanded, and they accordingly only charged 1s. for admission. For the present they had better accept the adjournment, and then decide what was best to be done. The meeting then adjourned until the 4th of June.

JUDGING TULIPS.

IN a circular on this subject, Mr. Barlow, the secretary to the Royal National Tulip Society, thus addresses the subscribers to that association:—"After full consideration, it has been proposed that on the morning of the exhibition on the 29th inst. twelve of the most prominent growers, men who are in every respect competent to judge the flowers, four from Lancashire, four from Derbyshire and Nottinghamshire, and four from Warwickshire and Yorkshire, be selected as judges; and that they be balloted for and divided into four lots, one from each section going into each lot. This will give four sets of judges, three judges to each set. One set will be sent to judge classes 1, 2, and 3; another, classes 4, 5, 6, and 7; another, classes 8 and 9; and another, classes 10, 11, 12, and 13. From other growers not engaged as judges, a sufficient number must be selected to assist the secretary in his duties, and also to assist the judges by assorting the blooms in the classes for single blooms. In judging the classes for single blooms the best flowers will be selected, but not labelled until the pans are all judged, and the losing ones carefully looked over, and the best flowers in them selected and tested against those already selected as the best among the single blooms. The advantages of this plan (says Mr. Barlow) are obvious. 1st. We shall save the expense of hired judges, say about £5, which sum will be more effective in the prize list. 2nd. We shall have the best judgment in the country, and should any judge be selfish enough to prefer his own flowers (a result not likely to happen, as every judge will be on his honour to judge impartially), he will always have two judges from a distance, not neighbours to contend against. 3rd. Congenial employment will be found for most of the exhibitors, instead of wasting time, as is usually done, in waiting for the decision of the judges. All the business can be got through in good time and everything finished, arranged, and in good order for visitors by one o'clock."

The Madder Plant.—Versmann states that the Madder plant has been cultivated in Holland for more than three hundred years; France (especially the neighbourhood of Avignon) now produces about one-half of all the Madder consumed, to the value of about £750,000 per annum. Turkey and South Russia also supply considerable quantities of high quality. Some experiments in cultivating Madder in this country were made in Derbyshire some years ago, but with indifferent results, though the plant is quite hardy in England. The Dutch Madder will dye red, but not purple, and the colour is not fast. Naples Madder dyes good red and purple, but the colours are not fast; that of Turkey dyes good red and purple, and is very fast. France supplies the market with two qualities, called "rosées," from their dyeing beautiful reds and pinks, and "paluds," which give a good purple, besides a fine red; this is the best French quality. The last name is derived from the fact that the plants are grown on marshy land.

The Food of Moles.—A correspondent of the "Field" communicates his knowledge of the movements of a tame mole now in the possession of Mr. Howlett, Newmarket. It is kept in a large propagating glass that holds about three pails of earth; and in this it works its subterranean passages and throws up the hills. Its food consists of earth-worms and wire-worms, and from the careful observations of Mr. Howlett it consumes daily about 100 worms, which are supplied every morning. It is quite at home, and feeds freely out of the hand of its master.

Grand Monarque Narcissus.—Amongst dozens of other varieties lately in flower this has been very conspicuous; some spikes of it have produced as many as eighteen and twenty blooms. For massing in beds or growing in pots it justly deserves to be extensively used everywhere. It belongs to the section of *Polyanthus Narcissus*. The individual blooms, which are large and pure white, have a yellow cup.—J. Muir.

French Beans at Burghley.—Your correspondent, "Ca Canny" (see p. 436) tries to be humorous; but that is an art that it takes many years to master. I would advise him to give up the endeavour, and try his hand at growing French Beans in pots. Let him obtain Red Flageolet, true to name, put four Beans in a 16-sized pot, when the flowers are open give the plant some liquid manure, and he will find no difficulty in obtaining a peck of Beans from forty pots all gathered at one time. We have had French Beans here all the winter; but just now (May 24th) we have plenty of young Peas, both Ringleader and William the First. Therefore our French Beans are now all clean cut.—R. GILBERT, Burghley.

Seedlings of Tropæolum Minnie Warren.—When writing recently in your columns of the merits of the variegated-leaved *Tropæolum Minnie Warren* as a bedding plant, I stated, as an additional recommendation, that it re-produced itself true from seed. I have now to inform such of your readers as take an interest in the forms and causes of variegation in plants, that I have learned from further observation that although the seed of this beautifully variegated plant germinates with great facility, and produces seedlings with three and four leaves, yet these seedlings cannot live, being destitute of chlorophyl; or, in other words, are altogether of a creamy-white, without any green in either leaves or stem whatever; they consequently soon dwindle away and die. The only way, therefore of re-producing this plant is by means of cuttings, which, fortunately, root with the utmost facility.—W. E. G.

IRRIGATION OF MARKET GARDENS.

MARKET-GARDENS, by reason of the greater value and constant succession of the crops raised upon them, will, in most cases, permit the application of more costly methods of irrigation than any other cultivated grounds, and from their smaller area there is less difficulty in procuring an ample supply of water. Few gardens are so situated

Fig. 1. Windmill for raising water.

that water can be procured from a stream without the employment of a water wheel or other motive power, a force pump, with pipes laid underground, and a reservoir in which water may be stored when not needed. But nearly every one may be supplied from a well by the use of a windmill. A windmill of the smallest size made, costing about £20, is able to raise one quart of water per second to a height of 75 feet. Such a windmill may be constructed by an ordinary mechanic

at a cost of from £2 to £5, which will answer every purpose of those manufactured and sold at higher prices, excepting that of regulating themselves to the varying forces of the winds. A mill of this character (fig. 1) may be fixed in a frame over the well, and the arms, of which there may be six, eight, or more, with fans fixed so as to present their faces at an angle of 45° to the wind (fig 2), are kept in position by means of a vertical vane behind them. Another, which consists of six arms mounted upon a rotating frame, carries cloth sails (fig. 3). A crank is attached to the axis of the wheel which works the pump-rod. This mill requires to be changed as the wind changes, and a ladder is attached to the frame upon which it is mounted for this purpose. A one-horse railroad power would also serve a useful purpose in raising water from wells into an elevated reservoir, where it could be stored for use.

Fig. 2. Fans of Windmill.

For small gardens, the water from the roofs of the buildings may be collected in tanks or cisterns, raised at least 12 feet above the level of the ground. A round tank, hooped with iron bands, 12 feet deep, and 15 feet in diameter at the centre, will hold over 15,000 gallons. A square tank may be made of planks, jointed and matched, which are forced closely together by

wedges, acting upon a timber frame which incloses the planks. This is the cheapest kind of tank that can be made. One 16 feet square, and 10 feet deep, will contain nearly 20,000 gallons. Tanks of this character can only serve for small gardens, or to store water which is pumped at night for use during the daytime. Either of these tanks, if filled during the night (to do which will require a stream from a pipe of an inch-and-a-half in diameter constantly running), and replenished during the day, will furnish enough water to give more than 1 inch in depth over an acre of surface. This is the least quantity that could be depended upon in a dry season for any effective purpose, and would need repeating at least after four days, so that the maximum effort of a tank of

Fig. 3. Windmill with cloth sails.

this size, with a well, windmill, or horse-power attached, would suffice only on an emergency to water 4 acres of land. When the ground to be irrigated is of larger extent, the supply of tank room and water must be enlarged, or the diameter of the pipe and the power increased. The capacity of the pipe increases as the square of the diameter; by which is meant that, if the diameter is doubled, the capacity is quadrupled. Thus, if a pipe 1 inch in diameter supplies 1 quart per second, a pipe of two inches diameter will furnish 4 quarts per second (or 2 multiplied by 2), and a pipe of 3 inches diameter will yield 9 quarts (or 3 multiplied by 3) per second. At the same time the power must be increased proportionately to the amount of water elevated, or disappointment will result. In estimating power a large allowance must be made for loss. A horse working in a railway power can only raise an equivalent of three-fourths of his weight; the rest disappears in friction; and when a stream of water is forced through a pipe of small diameter for a considerable distance, the loss of power in friction is very large, and another fourth of the horse's effort must generally be allowed to compensate for it. One horse may be expected to raise 180 quarts

1 foot high every second, or 6 quarts to a height of 30 feet. The small-size windmills are about one-sixth of one horse-power. Where streams are available, the supply of water will be found most ample and economical. No storage tanks are needed in which the water must remain for a time of lesser or greater duration, that its temperature may be raised nearly to that of the soil, as when wells are used. The water may be taken directly from the stream and flowed upon the ground. A low dam of 2 feet in height may be constructed of planks across the stream, by which power to run a small undershot wheel may be secured. Where there is facility for backing the water to a greater extent, or of procuring a greater fall, a breast-wheel may be used. A dam 4 or 5 feet high will be sufficient for a wheel of this kind, if the stream is 4 feet wide and 6 inches deep, and runs with a velocity of two miles per hour. Such a stream with this fall of water would give sufficient power to elevate about 6 or 7 quarts of

Fig. 4. Covered cistern for holding water.

water per second a height of 30 feet, or a sufficient supply for about 7 acres of ground. To calculate the nominal horse-power furnished by a fall of water, the velocity of the stream in feet per minute, the height of fall, and the sectional area (the width and depth) of the stream in square feet must be multiplied together and divided by 33,000.

If it be found necessary to store the water thus elevated so as to extend the area that may be irrigated, cisterns of substantial construction will be required. These should be of brick or stone laid in cement, or hydraulic lime, and strengthened with buttresses upon the outside. A bank of earth should then be heaped up around it and sodded or terraced; in the latter case it will be utilised by planting it. Such a tank, of considerable size and great utility (see fig. 4), may be dug in the ground at the highest part of the garden, to such a depth that the soil excavated will make a retaining bank to

Fig. 5. Open cistern for holding water.

support the portion of the wall that is above the surface of the ground. This tank, which is circular, may be covered with an arch of brick-work, and may be surmounted by a tool-house or other useful building. In this case a brick shaft 2½ inches thick each way

should be built in the centre, from which the arch would spring to the circular wall of the cistern; the wall should be 9 inches thick, and the bottom may be either of bricks laid flat or of cement laid upon the earth. This cistern, if 20 feet in diameter and 12 feet deep, would hold 30,000 gallons, or enough to water over 3 acres at one time. If the cistern is open the wall could slope outward, making an inverted frustrum of a cone (as seen in fig. 5), 32 feet wide at the surface, and 8 feet wide at the bottom. The earth thrown out of the bottom will form a support for the upper portion of the wall. But before the wall is built the earth thrown out should be solidly rammed down in layers made hollow or of the form of a basin. This form is shown by the curved lines in that part of the engraving. There is a large variety of pumps adapted to the purpose of irrigation, but the severe uses to which they are put make it desirable to have only those which are constructed entirely of metal. Leather valves are soon worn and become useless, causing delays and serious loss of time in repairs. The double-action force-pumps with

Fig. 6. Section of double-acting force pump.

metal valves, or the rotary pumps of the ordinary kind with metal pinions which work into each other similarly to cog-wheels, or those which work upon the old-fashioned principle of the Archimedian screw, but which, nevertheless, are protected by a modern patent, are all suitable for this work on account of their durability. A double-acting force-pump of the most simple character (fig. 6), made almost entirely of wood, is one of the best for that purpose on account of its cheapness and the ease with which it may be kept in working order. It is formed of a block of wood (A A), in which two parallel holes are bored lengthwise. In these holes the plungers (B B), made of wood—maple being preferable—are worked by rods affixed to a rocking shaft in connection with the power above the ground. Between these holes a smaller hole, shown by the dotted lines, is bored. This bore

is made to communicate with the other two by a hole bored from the outside (seen at *c*—that portion shaded, and where the letter is seen, being afterwards plugged up). A leather valve is placed so as to close the ports of this last hole, and turn the current of water into the pump-tube. This valve is inserted into a dove-tail mortice cut in the bottom of the plank. A slotted plug (*d*) holds the valve, and is placed and fixed in a proper position in the mortice. The lower portion of the mortice is closed with a plug. To insert the slotted plug, a hole is bored and the bottom of the block is sawn into to give room to chisel away the space in which the valve works back and front. The pump-tube may be a log bored and inserted into the block (as shown at *e*). Half-inch iron rods may be used to work the plungers. This simple but useful pump requires for its construction only those materials that are available everywhere, and only such skill as is possessed by any village carpenter or mechanic.

Distribution.

An adequate supply of water having been obtained, the preparation of the surface is the next work. For gardens this should be very complete, as the work will be permanent, and the first outlay will be the last, if the work is properly done. The method of laying out the ground will depend greatly upon the nature of the surface. If it is perfectly level, with no perceptible slope in either direction, the method of bedding should be employed. This is done by ploughing the land in ridges of such a width as will be most convenient for the culture carried on. For market gardens where horse cultivation is practised, these beds may be from 20 to 30 feet in width. In smaller gardens in which the hoe is used, and hand labour employed in cultivation, ridges of 10 to 12 feet in width will be found most

Fig. 7. Section of ridges.

convenient. Where the spade is used altogether, and horses are never admitted, the ridges may be made even of less width, the proportions in all these cases depending altogether upon the convenience or the necessity of the cultivator. The system here described applies to each of these cases. The ground is laid out into plots of a convenient size, which run completely across the garden or enclosure in a direction parallel to that of the main water-furrow from which the supply is to be derived. In case the garden consists of 4, 8, or 10 acres, or less or more than either of these quantities, a proper width of these plots would be 210 feet. This size would be the more convenient, as 210 feet is as nearly as can be had in practice the length of the side of a square acre. Besides, this distance is as great as water can be made to run in a furrow in ordinary garden soil, without being all absorbed before it reaches the extremity. Between these plots sufficient spaces will be left for

Fig. 8. Plan and section of beds and canals.

roads, if any are needed, for carts or waggons to pass through. These plots are then divided into other plots of the width designed for the ridges. They are then ploughed, and the ridges "twice gathered,"—to use a ploughman's expression—which means that a back furrow is made in the centre of each of these secondary plots, and the furrows are thrown each way towards the back furrow until the ridge is completed. The ground should then be rolled. Then another back furrow is made over the first, and the ridge is ploughed as before, making each of the furrows shallower than the preceding one, so as to leave a gentle slope from the crown of the ridge towards

the open furrow on each side of it. (The ridges then will show an outline, as seen at fig. 7.) At the head of each row of ridges or beds the ground is ploughed into a headland or ridge, which is thrown towards the first made ridges, and which lies at right angles to them, sloping gradually away from them to the fence or

Fig. 9. Section of head-ridge and bed with its canal of supply.

outer boundary of the enclosure, the last furrow made being ploughed deeply so as to provide a ditch for draining the headland. The principal canal of supply for the range of ridges below it will run along the crest of this headland, and a canal of distribution will run along the crest of each of the secondary ridges. Each headland or principal ridge, with its canal, and the range of ridges starting at right angles from it, each one of them having its distributing canal, will then form a system of irrigation independent of the other series

Fig. 10. Section of general arrangement of supply canal.

of ridges. Every seven of these secondary ridges, if they are 30 feet wide and 210 feet long, will occupy 1 acre of ground. At the foot of each series will be needed a draining furrow, unless the ground is underdrained with tile, to carry off the surplus water. A tile drain between each pair of beds or secondary ridges would be the best method of drainage, and the supply of water should be regulated so that the whole is absorbed, and none is allowed to flow away unused. (The series of beds and canals will then appear, as shown in fig. 8, in which three secondary ridges (*a a a*), with the head-ridge (*A B*) and the canals (*c c c*) belonging to each are shown, with the tile-drains (*d d d*). The arrows show the direction in which the water flows. Fig. 9 shows the profile of the ridge and section of the

Fig. 11. Plan adopted for hill cultivation.

Fig. 12. Wooden gate for closing canals.

head-ridge with its canals of supply as if they were cut down through the centre, *A* being the head-ridge with its canal, *a a* the bed or secondary ridge, *c* the drain at the foot of the bed, and the double dotted lines show the course the tile drain would take below the surface should one be laid. Where the ground has a slope in either direction, the system to be adopted will be much simpler than the preceding one. At the head of the slope will be placed the canal of supply. This will be the only permanent work undertaken. The method of cultivation of the field or garden will control the method of distributing the water. It will be necessary, however, to cultivate the ground in drills or hills, or subordinate beds, upon which the water may be turned when it is needed, leading it by small furrows or canals, made with the hoe or a small hand plough in whatever direction (down or across the slope) may be desired. (Generally the arrangement of the canals of supply will be as shown in fig. 10, in which the supply canal is seen at *a*, and the drain which carries off the surplus water is seen at the foot of the slope at *b*). A low ridge separates the latter from the next supply canal. In this method of irrigation, the water may be supplied as a thin sheet flowing over a smoothed surface, or as a number of small streams flowing in a network of courses over the surface or in regular channels between the drills or rows of plants. The ground may be laid out upon various plans, as the method of cultivation adopted may require. A plan (see fig. 11) adapted for a crop cultivated in hills or drills, each drill forming its own furrow of distribution in which the water may flow, is as follows:—A supply canal (seen at *a b*) is made at the highest part of the ground, with several short canals connecting it with a distributing canal (*c d*). From this distributing canal the water flows into the furrows (shown by the fine lines). The field is watered in sections by closing the canal at

any desired place (as at *e f*) with a sheet-iron plate or wooden gate (shown at fig. 12, in which is seen the gate, and at fig. 13 the method of its use). Obviously by shutting the canal in this manner the irrigation is confined to the portion of the field circumscribed by the closed furrow (shown by the dotted line *ff*, in fig. 11). The direction of the water is shown by that of the arrows. Where the slope of the ground is too abrupt to admit of very long furrows, a different plan (shown in fig. 14) may be adopted. In this the supply canal (seen at *a b*) is the same as previously described. From this the lateral canals (*c c c*) are made, each of which supplies its own dependent furrows, and no more water is admitted to these canals than will water the surface to which it is tributary. These canals gradually decrease in size until they disappear at the boundary of the field or garden. The

Fig. 13.—Wooden gate in use.

water flowing from these lateral canals takes the direction shown by the arrows. A more elaborate arrangement will be suitable in those cases where a variety of crops, each needing especial treatment, are grown. (Such a one is shown at fig. 15). In this the water is supplied by one or two canals (*a b* and *a c*), as may be consistent with the slope of the ground. A road (*d d*) is laid out at one side of the plot; a portion of the ground (*e e*) being retained for cultivation, leaving room to turn a cart or waggon at each end of it. The water is turned from the main supply canal (*f*) into the main

Fig. 14.—Plan of irrigation where the slope is abrupt.

distributing canal (shown by the double lines). The ground is laid off into plots suitable to the system of culture (as at *G H I J K L*). These may be irrigated in various ways, as, for example, by long furrows (at *G*), in smaller beds with shorter furrows (as at *I*), or in furrows running in an opposite direction (at *K*). The flow of water in the distributing canals is controlled and diverted by means of the hand-gates already described (the arrows show the direction of the

Fig. 15.—Plan of irrigation suitable to market gardens.

various currents). A plan for a garden very completely irrigated by means of a well or reservoir may be laid out as follows (see fig. 16). A road passes through the centre and around the plot. The well and reservoir, windmill or horse-power, is situated at the highest part of the ground (see *A*). From this the water is conveyed by channels to the lower part of the garden. From these channels it is distributed in small furrows to every row of plants or bed of vegetables. (The arrows show the direction of the flow of water.) For a small garden this system is doubtless the most perfect of all methods of irrigation by surface channels and furrows; while for larger ones or market

gardens, in which the supply of water can be procured from wells or carried into reservoirs for final distribution, it is equally perfect.

Fig. 16. Plan for irrigating a garden from a well or reservoir.

The form of the channel deserves consideration. The typical canal or furrow (shown at fig. 11) is one in which the earth thrown out forms a bank above the channel, preventing the influx of water from a neighbouring channel, while the lower bank is not raised, and permits the escape of a thin sheet of water over the ground below it. There are many other forms of furrow available which will occur to the practical operator as they may be needed. But there are some methods of strengthening the furrows against degradation by the currents of water worthy of notice.

One of these (shown at fig. 12) consists of a trough of wood, two strips of 4 or 6 inches in width being used. These are nailed together by their edges, and imbedded in the furrow. The water in passing along is prevented from escaping into or from flowing over the soil except at the open side of

Fig. 17.—Section of typical canal or furrow.

the trough. A portable wooden trough (fig. 13), with cross channels, may be used to convey water over ground that is under cultivation or is not in a condition to be disturbed with the hoe. This trough is peculiarly adapted for use in the system of bedding here described, as it may be laid upon the crest of the head ridge, and the cross channels connected with the furrows upon the crests of the beds. These latter may be made of common open horseshoe drain tiles inverted. The uses to which this kind of drain tiles may be put in

Fig. 18. Method of strengthening furrows against currents of water.

surface irrigation are very numerous, but they will be so obvious to those interested that it is necessary only to suggest their usefulness in this respect.

Garden Irrigation by Pipes and Tiles.

Many elaborate improvements have been made within the past few years in the practice of irrigation. The costly character of these improvements renders them inapplicable to any lands except those upon which the crops are of great value. The minimum value of the crops that may be profitably raised by the methods of irrigation referred to may be placed at £80 per acre. In some cases where the profitable use of land depends entirely upon these costly plans this minimum may be reduced considerably. Thus, rather than have land idle it may pay to expend a permanent capital of £50 per acre, the

Fig. 19. Portable wooden trough with cross channels.

yearly interest of which, with the annual cost of water and labour, may, on the whole, result in a yearly outlay of £20 per acre to produce crops which may realise £50 to £60 per acre. For a market garden these amounts are much less than the average value of the crops produced, and many seasons occur in which the losses by reason of dry weather at critical periods will amount to far more than the total value of the improvements here to be

described. The simple fact that in many cases the crops which, under favourable circumstances, should have realised £80 to £240 per acre, have been so injured by drought as to fail to pay the cost of production, is sufficient to induce the gardeners and fruit growers

to adopt methods of securing a full crop in spite of the drought. There are many cases in which the methods of surface irrigation previously described are unsuitable. Where the services are irregular, where the crops are changed several times in a season, where the ground is under biennial or perennial crops, and furrows cannot be maintained, or where the ground is too valuable to be occupied by furrows or water channels, these and other conditions will be favourable to the use of one or another of the following described plans. The first to be treated of is that of underground pipes and stationary hydrants, from which water may be distributed under pressure through indiarubber hose and sprinklers. An elevated reservoir is provided, from which an iron pipe having a capacity equal to an inch-and-a-half in area for each acre to be irrigated is carried along the centre of the garden. A 2-inch pipe will be required for 2 acres, a 3-inch one for 4 acres, and a 4-inch one for 8 acres. From this other pipes are carried at right angles 200 feet apart to within 100 feet of the boundary upon each side. The pipes are laid a foot beneath the surface, or so far that they can never be disturbed by the plough. Upon the lateral pipes, which should be at least an inch-and-a-half in diameter, so that the flow shall not be unduly interrupted by friction, upright pipes or hydrants are attached which project at least 3 inches above the surface of the soil. These are about 150 feet apart. They are furnished with valves which operate by means of a square head and a key. Each one is fitted with a cap which screws on or off, and which is attached to the hydrant by a short chain for its preservation. When this cap is unscrewed a section joint affixed to the end of the hose may be screwed in its place. When this apparatus is in operation the water descending from the elevated tank or reservoir passes through the pipes and the hose and escapes with some degree of force, depending upon the height of the head, through a flattened nozzle, which scatters it in a thin sheet or broken shower. With this apparatus one may water copiously 5 acres of ground in a day or night. Each hydrant being the centre of a plot 200 by 150 feet, serves to irrigate, with 100 feet of hose, very nearly three-quarters of an acre of ground. To irrigate 5 acres in ten hours would give an hour-and-a-half to each plot, an amply sufficient time for an active man to get around a plot of 200 by 150 feet. The plan here described is illustrated in the foregoing figure. The well, with reservoir, wind-mill and force-pump, is situated in the centre of the plot to be irrigated at A. From this the pipes (shown by the double lines) are carried as has been described. The points marked upon the lateral pipes show the positions of the hydrants, and the dotted circles around a few of them show the extent to which the hose covers the ground. A plan of sub-soil irrigating by means of drain tiles has been in operation for many years, although a recent patent has been granted in the United States for the invention. The patent refers to perforated tiles. But the common drain tiles will answer every purpose that the perforated pipes can or will. The plan is very simple. It is exactly the reverse of draining by tiles. Large pipes—the size being chosen to suit the system tributary to them—are laid down, a foot beneath the surface, at the highest part of the tract to be irrigated. From these, smaller pipes branch as the secondary channels of supply, and from them 1-inch pipes again branch as distributing channels to the limits of the tract. The water escapes through the joints of the pipes, and rises by capillary attraction or absorption to the surface of the soil. As the water will naturally tend to sink in the soil in a greater measure than it will rise to the surface, the distributing pipes will need to be placed very closely. A distance of from 6 to 8 feet apart will be the greatest that should be allowed. This system has the advantages of cheapness of material, of permanence, and of economy in applying the water. But it possesses the disadvantages of large cost of labour in laying the tiles, and of a very wasteful expenditure of water, a large portion of it escaping downward uselessly to the crop. The trenches in which the tiles are laid may be very cheaply made by ploughing twice or thrice in the same furrow until it is 12 inches deep, and when the tiles are laid most of the earth may be ploughed back into the furrow again. For any sort of favourable result the slope of the ground must be regular, or the arrangement of the tiles must be made with costly exactitude.

Fig. 20. Plan of irrigation by underground pipes and stationary hydrants.

is fitted with a cap which screws on or off, and which is attached to the hydrant by a short chain for its preservation. When this cap is unscrewed a section joint affixed to the end of the hose may be screwed in its place. When this apparatus is in operation the water descending from the elevated tank or reservoir passes through the pipes and the hose and escapes with some degree of force, depending upon the height of the head, through a flattened nozzle, which scatters it in a thin sheet or broken shower. With this apparatus one may water copiously 5 acres of ground in a day or night. Each hydrant being the centre of a plot 200 by 150 feet, serves to irrigate, with 100 feet of hose, very nearly three-quarters of an acre of ground. To irrigate 5 acres in ten hours would give an hour-and-a-half to each plot, an amply sufficient time for an active man to get around a plot of 200 by 150 feet. The plan here described is illustrated in the foregoing figure. The well, with reservoir, wind-mill and force-pump, is situated in the centre of the plot to be irrigated at A. From this the pipes (shown by the double lines) are carried as has been described. The points marked upon the lateral pipes show the positions of the hydrants, and the dotted circles around a few of them show the extent to which the hose covers the ground. A plan of sub-soil irrigating by means of drain tiles has been in operation for many years, although a recent patent has been granted in the United States for the invention. The patent refers to perforated tiles. But the common drain tiles will answer every purpose that the perforated pipes can or will. The plan is very simple. It is exactly the reverse of draining by tiles. Large pipes—the size being chosen to suit the system tributary to them—are laid down, a foot beneath the surface, at the highest part of the tract to be irrigated. From these, smaller pipes branch as the secondary channels of supply, and from them 1-inch pipes again branch as distributing channels to the limits of the tract. The water escapes through the joints of the pipes, and rises by capillary attraction or absorption to the surface of the soil. As the water will naturally tend to sink in the soil in a greater measure than it will rise to the surface, the distributing pipes will need to be placed very closely. A distance of from 6 to 8 feet apart will be the greatest that should be allowed. This system has the advantages of cheapness of material, of permanence, and of economy in applying the water. But it possesses the disadvantages of large cost of labour in laying the tiles, and of a very wasteful expenditure of water, a large portion of it escaping downward uselessly to the crop. The trenches in which the tiles are laid may be very cheaply made by ploughing twice or thrice in the same furrow until it is 12 inches deep, and when the tiles are laid most of the earth may be ploughed back into the furrow again. For any sort of favourable result the slope of the ground must be regular, or the arrangement of the tiles must be made with costly exactitude.

Liquid Manure.

The ordinary cultivation of gardens exhibits a most striking want of economy. Market gardens, and those smaller ones attached to village

dwelling, ought to be cultivated in accordance with the strictest economy. Not a drop of rain-water ought to be allowed to go to waste. The house-slops should be carefully utilised. The cesspool, the stable, and the refuse heap ought to serve the useful and appropriate purpose of aiding in the production of the household vegetables and fruits. But on the contrary, it is doubtful if they are so utilised completely in any establishment even where the means exist. Partially they have in some few cases been made to serve their proper purpose with the best effects. It is in densely-populated countries that liquid manuring has been brought into use, and these valuable materials made serviceable. Without going so far as China and Japan for examples of this economy, it may be stated that Belgium, the most thickly-peopled country of Europe, offers the nearest and most conspicuous example of the preservation of every kind of animal manure, both solid and liquid, and its manipulation in tanks for the purpose of applying its solution or dilution to gardens and small farms. In many parts there is an arrangement of house drainage, combined with garden irrigation, recently brought into use that has been tested with satisfactory results, and that is full of promise for its future general adoption. This grew out of the successful application of the system of earth closets to some cottages in a village in the county of Essex. The vast superiority of these over the common filthy cess-pools makes more conspicuous than ever the inconvenience, insalubrity, and waste of the usual slop holes where the liquid waste of the house was disposed of. For sanitary purposes a method was devised to dispose of this waste, and for economic purposes a plan of utilising it was adopted. From the sink of the kitchen a pipe furnished with an air-trap (a) was made to discharge into a tank built of cement concrete outside of the wall of the house. (This tank is seen in the figure below, A being the sink in the kitchen with the pipe and trap). The rain-water from

Fig. 21. Self-acting flush tank.

the roof of the house is carried to the tank by a pipe (b) which also serves for ventilation. The tank is simply an underground cistern made water-tight, and lined with hydraulic cement. The overflow from the tank is made intermittent by the ingenious use of a syphon (seen at c c). The operation of this overflow is simple. When the cistern is filled to the moveable cover (d), the water then trickles over the bend of the syphon into the drain (e). When this occurs, the discharge of a pailful of water into the sink, and through the pipe into the tank, suddenly fills the pipe, flushes the syphon, and sets it in operation, and the tank is drained to the level of the shorter leg of the syphon. The contents of the cistern flows away by a pipe (f) which leads from the drain. This tank is called the "self-acting flush tank." The cover (B) is a moveable plank floor which serves to allow access to the tank for any purpose. But this leads to the real subject matter in hand, the irrigation of the garden. By this plan, this can be secured whenever it is desired by simply introducing into the tank water sufficient to set the syphon in operation. The liquid then passes into the drain, and from that into sub-drains of 1-inch drain tiles placed 1 foot beneath the surface, escaping through the joints into the soil. The second figure shows this arrangement. The outer lines represent the boundary of the garden plot, supposed to be an eighth of an acre, or 50 x 100 feet. The tank is seen at d; the dark line proceeding from the tank is the drain; the thinner lines are the irrigating drains; the square dots are inspection wells, covered with a square stone or plank cover, by which examinations are occasionally made as to the condition of the drains, and the parallel lines in the centre are land drains which carry off any excess of moisture. This plan is of very

extended applicability where the land to be irrigated may be beneath the level of the site of the house and the tank, and no house should be built upon a lower level than the ground around it. An improved tank, suitable to dwellings of a somewhat superior character is shown in the concluding figure. The principle is exactly the same as that previously described, the material of the tank being different. It is cylindrical in form, and may be of galvanised iron, of zinc, lead, or wrought iron, or of hard brick laid in cement. The discharge pipe may be of cast iron. This form of tank has been found to work with the greatest ease; two quarts of water suddenly discharged into it when full being sufficient to set the flush into operation. This apparatus consists of the cylindrical tank (a), with a trapped inlet (b), which also forms a moveable cover to give access to the inside of the tank. The pipe from the sink discharges over the grating of the inlet (as shown on the figure). A socket (c) is prepared for a ventilating pipe. There is also the syphon (d), and what is called the "discharging trough" (f), consisting of a small chamber, made to turn round, so that its mouth may be set in the direction that is required for connecting it with the line of outlet pipes (g), and provided with a moveable cover for access to the mouth of the syphon. This "discharging trough" is an important feature in the tank, as it is of a peculiar shape, which, by checking the outflow of the liquid from the mouth of the syphon, enables a smaller quantity of liquid flowing into the tank to fill the bend of the syphon and set it fully in action. The danger of filling up the pipes with sediment would prevent the application of this system to the use of matter from cesspools or barnyard manure tanks. It would not, however, prevent its use for the purpose of discharging a cesspool through a pipe of sufficient diameter—4 to 6 inches, for instance—into a manure tank in the stable-yard, where it could be mingled with the liquid draining from the stables. This tank would then form the cesspool; the overflow from the house tank passing into it would flush and cleanse the latter at every considerable shower. A good supply of liquid matter of the very richest fertilising power would then be at hand for use by means of permanent or temporary irrigation. The liquid would need to be raised from the cistern by a pump worked by wind or

Fig. 22. Plan of irrigating drains from self-acting flush tank.

Fig. 23. Improved self-acting flush tank.

horse-power, as has been already described, and conveyed through large pipes into the distributing channels. These could be permanently made of inverted horseshoe tiles, or in any of the methods heretofore mentioned, or temporarily by the use of the hoe. It would be necessary to use caution in largely diluting the liquid manure; a dilution that would run off perfectly clear might be of sufficient strength for all purposes. The danger lies in using it of too great strength rather than in diluting it too copiously. It has been found in practice after a heavy rain had filled the tanks with water at a season when there was but a very small supply of manure on hand, so that the dilution was certainly not less than a hundred times, that the use of this weak liquid, in a succeeding day, gave a stimulus to the crop.

Irrigating Orchards.

In countries liable to suffer from drought the most extraordinary results are obtained in orchards by irrigation. The methods of irri-

gating orchards are very simple. It is necessary only to put the water where it will do the most good, and that is as near as possible to the extremities of the rootlets. The extent of the roots of a tree bears a ratio somewhat approaching that of the branches. Near the stem there are few of the spongioles by which nutriment is absorbed. They are found at the extremities of the very fine rootlets, and these exist in a ring around the tree, the inner side of which is from 3 to 4½ feet distant from the stem. In irrigating an orchard, then, the most perfect method of applying the water is to distribute it in a broad circular channel around the tree distant about 6 feet from the stem. Where irrigation of orchards is practised two different plans are adopted. The first is a somewhat rude method, but is easy and effective. The water is led into a channel between two rows of trees (a b fig. 24), and from thence into distributing canals (c c c) which carry the water within a few feet of each tree. (The position of the trees in the figure is indicated by the dots.) Here a sharp bar is thrust into the ground in several places, penetrating in different directions towards the roots and leaving holes by which the water soaks into the earth and reaches the roots. The second is a more elaborate but a preferable method. The water is led from the canals into circular furrows, which curve so as to embrace the tree. (This is shown at d e in fig. 24.) These furrows are broad and shallow, and the water overflows from them in a thin sheet or a multitude of little rills which lead to the lower side of the tree where they are arrested by means of a slight embankment raised with the hoe. In this case the water is brought exactly where it is needed, and every rootlet is supplied. As a rule irrigation and drainage should go together. Irrigation

Fig. 24. Irrigating an orchard.

without drainage, in most cases, will convert a tract of land into a morass. Stagnant water is fatal to the life of useful vegetation, and it is here that the causes of the failure of many attempts to irrigate originate. In arid territories without rainfall, skilful irrigation will apply such a quantity as will be needed to supply evaporation from the surface of the soil and the transpiration of the plants. If more is given the surplus must pass off through the sub-soil, or, remaining in, it will work mischief to the crop. But such an excess of water can rarely be procured in arid districts. On the contrary, the greatest economy must be exercised in using the limited supply and waste is impossible. It is otherwise in those parts of the country where partial or periodical irrigation is used. There the water supply may be copious, and the skill of the cultivator is to be exercised in conveying to the ground only so much as may be serviceable and no more. But to hit the just mean is a matter of difficulty. For safety, therefore, in these cases a system of drainage is imperatively needed.

The above valuable article is from the "New York Tribune," the cuts being re-engraved for THE GARDEN. Irrigation, though almost neglected, so far as our gardens are concerned, would be as great an aid to high cultivation in our dry districts as it has long been proved to be in other countries.

The Late Winter.—Mr. Ellacombe has supplied your readers with some valuable notes of the effect of the recent trying winter on out-door plants in Gloucestershire, and he invites similar lists from other places. The following plants of doubtful reputed hardiness have survived without injury on the West Coast of Scotland, viz.:—*Aloysia citriodora*, *Clanthus puniceus*, *Myrtus communis*, on a wall; *Fuchsia* (various hybrid kinds in open border), *Fuchsia Riccartoni*, *Desfontainea spinosa*, *Convolvulus Cneorum*, *Sparaxis pulcherrima*, *Arum crinitum*, *pictum*, and *serotinum*, and *Crinum capense*. The following have died or disappeared, viz.:—*Commelina coelestis*, *Primula mollis*, *Anomatheca cruenta*, *Antholyzas*, and *Eryngium bromeliæ-folium*. Nearly all the plants in a bed of *Verbena venosa*, which had stood the previous two winters wholly without injury, are dead. A bed of seedling Conifers from seed sown last year was left unprotected. It contained young plants of *Pinus insignis*, *Sabiniana*, and *macrocarpa*. Nearly all are dead, except *Pinus insignis*, which is quite healthy. A few young plants, however, of *Pinus Sabiniana* and *monticola* are now appearing from seed which has lain all winter. No established Conifers appear to have suffered here. *Cupressus sempervirens*, although rather browned in the points by the frost and high winds, is now quite green again, and not one of about fifty plants is seriously injured.—SALMONICEPS.

THE FRUIT GARDEN.

PEACH AND NECTARINE CULTURE UNDER GLASS.

THE Peach and Nectarine being very closely related, the same treatment answers for both. A consideration of the first importance is the composition of the border, which in the first place should be well drained, and if any of the sub-soil should be of an unfavourable character, it should be removed to the depth of a foot or so, and a layer of concrete, about 4 inches thick, put in, allowing an inch in a yard of fall from the house to the front of the border, to admit of the water running off into the drain, which must be made along the entire length of the border. Allow the concrete to harden before making the border; put on 7 or 8 inches of broken bricks or stone, cover it over with 2 inches of gravel, or any other material of a finer character, to prevent the soil from working into the drainage, which will now be about level with the top of the ground. All fruit borders should stand above the ground level. The width of the border should be from 12 to 14 feet. It should be 2 feet deep close to the house, running off to 18 inches at front. It is best to make it in separate parts—say, half the width to begin with, and the other half at two different times, as the roots extend. This gives fresh vigour to the trees at a time when they want it, and the border lasts longer. All stone fruit grows to the greatest perfection in strong heavy loam in limestone districts; but, as this is not to be met with in many gardens, good substitutes are to be found in sods of old pasture, which should be stacked up for two or three months before they are wanted. Get a few loads of good shelly marl, lay it in a shed to dry, so that it can be easily chopped with the spade; and, in making the border, chop the sods roughly, first covering the drainage with them, laying the grassy side down. Mix the sods, if light, with one-third of marl; if heavy and strong, mix in some old lime rubbish. It is better not to put any manure in, as this can easily be put on the top when required. Always avoid a light sandy soil, which will make plenty of bloom; but after the first or second year, very few fruits will set. Peaches may be safely planted from October to April; but it is best to plant them as early in October as possible, if the wood is firm and ripe. Every care should be taken in removal not to bruise the roots, which should be stretched to their full length, and covered with about 2 inches of soil, keeping the crown well above the ground, in order that room may be found for a top-dressing at any time. Give a good watering through a rosed can, and damp the foliage over with the syringe two or three times a day, according to the weather. The soil being warm the roots soon begin to grow, and if the trees are large you may have a good crop the ensuing season. The permanent trees should be allowed not less than 16 feet between them, as the fruit is finer, and the trees last longer when plenty of room is given them. Trees can be planted temporarily between them, and removed when their room is required. This is, however, often neglected, which is a mistake. As soon as the buds begin to grow they must have every attention in disbudding; this operation should not be completed all at once, but on several occasions. First, remove those buds on the front of the shoots that are misplaced, and in a week or ten days, go over them a second time, leaving the best placed and most promising shoots nearest the base. This is important to keep the tree furnished; in the course of another week or so go over them a third time, making a final choice for next season's fruiting, always leaving a shoot beyond the fruit, and watch any rank shoots that appear likely to take a lead; it is generally best to cut them out at first if they can possibly be spared, as they rob the other part of the tree. Be careful to balance the growth, so that one side of the tree does not outgrow the other. The ordinary fan system of training is best for general purposes. As soon as all the fruit is gathered, go over the trees and cut out all the useless shoots where the fruit has been, and leave nothing but what is required for fruiting the next season, thus concentrating the energies of the tree, and giving light and air to mature the whole length of the shoot, which assists in laying a good foundation for the next crop. If the superfluous shoots are not taken out, many of those that remain get badly ripened and, as a matter of course, produce few blooms the following season.

With regard to temperature, they should be shut up every afternoon when the thermometer is down to 80°, syringing every part of the tree freely to keep down red spider, and promote a genial growing atmosphere. At dusk admit air by the top ventilators, and leave it on all night, if the state of the weather renders it necessary. If it be very hot, give plenty of air as early as possible. This will give substance to the foliage and quality to the fruit, and will prevent both mildew and red spider to a great extent. A close damp atmosphere in the night, and a roasting in the morning before the ventilators are opened, injure both the foliage and fruit, and often cause many fruit to drop off prematurely. When the wood is well ripened, there are generally more fruit set than are wanted; these must be thinned—not all at once, but at intervals. When the fruit sets in clusters, remove all but the largest ones and those that are near the wires or behind the shoots. When they have attained the size of a large marble, go over them a second time, removing all the smallest fruit, leaving them thickest where the shoots are strongest; but discretion must be used in making choice of those that are to remain, according to the strength of the tree. The third thinning should not take place till the fruit are stoned; but, if they are thinned out two to a square foot at the second thinning, very few will fall in stoning; and, where fine fruit is the object, a few of those may be thinned as soon as stoned. As regards watering outside borders, much depends on the character of the weather and the nature of the soil; but, where the borders are inside, three or four waterings are sufficient, where the syringe is freely used—a thorough watering when the house is about to be started, another after the fruit is set, and a third as soon as the fruit is stoned. If the soil is not of a calcareous nature, give a few canfuls of clear lime-water, watering afterwards with clean water. It is a bad practice to allow the border to become dust-dry in the winter; it weakens the buds, and the blooms that do not fall never get larger than a Marrow-fat Pea.

JAMES SMITH.

Waterdale, St. Helens.

GUANO FOR FRUIT TREES.

A GOOD many years have passed away since I first used guano as a top-dressing for Vine borders, with very marked results, and since that time I have often used it, both in the shape of liquid manure and sprinkled over the borders, not only in the case of Vines, but also that of Peaches, Figs, Cherries, Plums, and other fruit trees, both indoors and in the open air, whenever I considered it necessary to assist a heavily-laden tree to finish off its crops without undue exhaustion. In a season like the present when, to judge from appearances, fruit crops in all parts of the country are likely to be much above the average, the question assumes an importance that would not be accorded to it when crops are scanty. Many of the evils resulting from over-cropping in an exceptionally fruitful season might be obviated by judicious feeding—not with solid manures, but with liquid stimulants. I feel confident that in gardens where, as a rule, the manure supply is never too large, a more extended use of what are commonly known as “artificial manures” would be attended with the most beneficial results. Peruvian guano is undoubtedly one of the best fertilisers to employ, where the object sought is to enable a tree to get over a difficult season without impairing its constitution. It is quick in its action, can be given just when it is required, and does not clog up the pores of the soil; but, of course, in no case should it be used, unless the state of the trees clearly denotes that some extra assistance is wanted. The age, strength, and condition of the trees, in fixing the quantity that may be applied, should also be considered. Generally speaking, about half-a-pound to each square yard of surface should be sprinkled round the tree, nearly as far as the roots are supposed to extend. I have often used guano in much larger quantities than I am now recommending, but its qualities vary, although not so much as many other artificial manures, and it is best, until experience has been gained, to err, if at all, on the safe side. I would rather always give two light dressings than one heavy one. In all cases, when sprinkled over the borders, the operation should be followed immediately with a good soaking of rain or pond water, unless the weather happens to be wet. A good deal of misapprehension seems to exist as to the meaning of the term “a good soaking of water;” it often happens that half-a-dozen potfuls poured round the trunk of a good sized tree is called a good soaking, when, in reality, it has only just moistened the surface. The truth is, in a dry season, in a

well-drained border, until the fruit begins to ripen, the only limit to the application of water should be the power to apply it, as it is next to impossible, in most cases, to over-water. The soil should be thoroughly saturated, if possible, down to the lower roots; and, if the borders are mulched, a fortnight may elapse before another application becomes necessary, unless the weather should be unexceptionally hot and dry.

E. HOBDAV.

Ramsey Abbey.

TOADS AND THE GOOSEBERRY GRUB.

MUCH has been written about the Gooseberry grub, and much also about the toad; but I am by no means sure that the two creatures have ever been linked together in the columns of your paper. They certainly seem an ill-assorted pair, an incongruous couple; yet some good may possibly result from the association. I recollect that, in the year 1848, a Mr. Leadbitter, of Gray's-inn Road, sent me a circumstantial account of the doings of a toad with the Gooseberry grub, an account that rivetted my attention at the time, and the impression of which remains sharp and clear on my memory after a lapse of twenty-seven years. The facts of the case were recorded at the time, and have been abundantly verified by subsequent observations of my own; here they are, as narrated by Mr. Leadbitter. This gentleman was staying near Dorking, and observed that three or four Currant bushes nailed against a garden wall were striped of their leaves by these ubiquitous garden pests, which were swarming all over the bare twigs and clinging to stumps of the leaf-stalks, the only indication remaining of leaves having once grown there. A few wretched bushes of Currants sufficed to show what the shrub desired to produce had the grubs permitted. Squatting on the bare earth, in the angle of the garden wall, was a corpulent toad waiting for "something to turn up," or, perhaps, speaking by the card, for "something to come down." The happy thought at once occurred to Mr. Leadbitter, that this "something" must be a Gooseberry grub, so he collected a quantity of these grubs, and readily induced one of them to crawl on the end of a short stick; this feat having been safely accomplished, he next presented the grub to the toad, who contemplated the dainty for a few seconds, with his head held knowingly on one side, and his eyes beaming with satisfaction. After a very short pause, the grub began to crawl up the stick, doubtless deluded by the notion that he was ascending into a region of Currant leaves. Then there was a movement of the toad's head and neck, and in an instant, in the twinkling of an eye, the grub was gone; he had descended alive into a living tomb—the stomach of the toad. The naturalist then continued to supply the toad with his living diet until his collection of grubs was exhausted. On the following afternoon, and so on day after day, Mr. Leadbitter and the toad repaired to the same feeding-place, until no more grubs could be found, and the toad had to go without his accustomed meal. At this he was so disappointed or affronted, that he returned no more to the feeding-place. The process of eating, as observed then by Mr. Leadbitter, previously by Mr. Bell, and subsequently by myself, is this:—The tongue of the toad is thrown forward, so as to touch the grub, and then as quickly withdrawn—the grub adhering to its extremity—and so swallowed. The whole process is inconceivably rapid—so much so, indeed, that only a practised observer would be aware of what had taken place. Being induced to pay great attention to the feeding of toads by what I had read, I believe I can positively assert that these most useful reptiles always require living food, and always wait for the object, be it what it may, to move before seizing it. I have never been able to induce a toad to seize a dead grub, or a dead fly, or motionless food of any kind, so that I feel very sceptical as to the truth of those amusing anecdotes of feeding tame toads on bread and milk, and other succulent preparations congenial to infant stomachs. Such stories have long received implicit credence amongst us; they have even been transplanted to American soil and have returned to us slightly altered, the harmless toad being transmuted into a venomous black snake, and a child represented as feeding him on bread and milk with a silver spoon. The season is now approaching for Gooseberry grubs to make their annual visit, and I wish to repeat what I have stated over and over again, that I have never found any remedy for their ravages. I utterly repudiate as worthless all chemical preparations of any kind, except whitewash. I cannot, indeed, doubt the efficacy of whitewash, but I question whether the cure is not worse than the disease. Then we come to the consideration of the toad remedy. I am perfectly willing to admit that this has also its difficulties, but I think these are not insuperable. In the first place, if you collect toads in a walled garden, they must of necessity remain there for a time; in the second place, if you shake the Gooseberry bushes of an evening the grubs must needs fall, and the toads will be sure to devour them, one at a time, as soon as they begin to crawl. The Gooseberry grub

always enters the ground before it can undergo its transformation. If the earth beneath the Gooseberry bush be trampled hard, it is difficult for the grubs to force their way beneath the surface, and, therefore, they wander about, exposed to birds by day and toads by night; thousands also fall a prey to carnivorous ground beetles, which seem to subsist entirely on night-walking worms and caterpillars. It is a noteworthy fact that very few birds have any weakness for the flavour of a Gooseberry grub; two only are known to me, the cuckoo and the redstart. I must by no means be understood as enunciating any rule on this subject, or even as saying that Nature imposes a positive law on her birds; but, as I keep a good many of our common species in rather a capacious cage, I have abundant opportunity of testing their tastes in this matter, and I never could detect any species in the act of eating one of these grubs. On the other hand, I have already published the fact that cuckoos and redstarts devour them with avidity; but how to induce these summer visitors to come into one's garden is a problem that I have never been able to solve.

And here I may just hint that the well-known song of the cuckoo, and the equally familiar white forehead of the redstart, always precede the advent of this enemy of the gardener—an enemy that invariably remains to annoy us until both cuckoo and redstart have taken their departure; then he buries himself, with the motto "I shall arise again," as it were, on his lips—a prophetic promise which he is certain to perform to the very letter when the cuckoo returns next year. A word as to hardening the surface of the soil. I believe it a great error in the gardener to make any rule too absolute on this subject. There is little doubt that hardening the surface sometimes interferes with the free growth of plants. As this is probably the case, I shall make no attempt to raise the question; but I have yet to learn that the free growth of a Gooseberry bush is essential to its fruit-bearing capabilities. Indeed, I have often thought that rapid and luxuriant growth was antagonistic to fruit-bearing; and, if this be so, the hardening of the surface-soil, by preventing too luxuriant growth, is likely to be beneficial rather than injurious. I think we are all too much inclined to make gardening laws of too general application, and thus to argue that, because the lightest possible surface is desirable in the cultivation of tender annuals, it must also promote the fruit-bearing of Gooseberry and Currant bushes. This reasoning will not hold good. Nature has created one insect enemy of the Gooseberry grub, a species of *Chrysopa*, or lace-winged fly. There may be others; indeed, it is most probable there are others, but I have not detected them. This enemy is of very beautiful appearance, but of very disagreeable scent; it has four wings of exactly similar size and character, delicately reticulated like gauze, a green body and head, and two brilliant golden eyes. So far it is a loveable and an attractive creature; but, when you touch it, when you take it up to admire, then it emphatically protests against the proceeding, and, in order to ensure obedience to its protests of touch-me-not, emits such an insufferable disgusting smell, that you are glad to get rid of it, and literally to wash your hands of so offensive a creature. In my life history of plant lice, published in the "Field" of Sept. 30, 1871, I gave a figure of this "lace-wing," together with its eggs and larvæ. I there mentioned two other names by which it is well known to entomologists, "golden-eye" and "aphis-lion"—names that show how well it is known, and how correctly one of its habits has been observed. Well, this fly hovers lazily about the Currant or Gooseberry bushes, wherever she observes the parent flies laying their eggs. After a short survey, she selects a particular leaf, the veins of which, so prominent on the under side, have just been beaded with the oblong eggs of the Gooseberry grub; then, feeling perfectly satisfied that there is abundant promise of provender for her future family, she proceeds to the very edge of the leaf, and, discharging a drop of glue, lifts up her body, and the glue, being pulled out to the length of half-an-inch or more, is thus formed into a thread, which immediately hardens and becomes a stiff and permanent bristle; at the extremity of this she affixes an egg, and then repeats the process, until there are six or eight of these eggs standing side by side, each on the top of a long bristle. I need not again describe how the little grub in due time breaks its egg-shell, and emerges from its prison-house in the form of a very minute lizard, with six legs instead of four, a distinct head and neck, and a pair of curved and sharp-pointed jaws. These jaws, although wide apart at the base, yet by means of their curved form meet at the tips, and thus constitute a pair of most formidable and effective pincers for worrying the little Gooseberry grubs, which make their first appearance on the stage of life about the same time. Then follows a repetition of the old story of the young wolf-cubs and the lambs—at first they play together in frolicsome harmony; but, as soon as the wolves begin to feel hungry, they eat up their playfellows. It is thus with the young of the lace-wings and the Goose-

berry grubs—at first it is all serenity, a state of peace; but both very soon get hungry, and then the grubs devour the Gooseberry leaves, and the lizard-like larvæ of the lace-wings devour the grubs; a scene of carnage ensues—a regular “massacre of the innocents.” My tale is utilitarian. If you would protect your Gooseberry and Currants from the grub, first bring toads into your garden—toads of all sizes, big and little; secondly, tread the earth hard under the bushes; and, thirdly, never kill a lace-winged fly.

York Grove, Peckham. EDWARD NEWMAN, in “Field.”

[Strawberries on Railway Embankments.]—I had the pleasure of seeing perhaps half an acre of these the other day on a railway embankment. They were planted thickly and broadcast, the whole ground being covered with them; and they were loaded with bloom. Perhaps this is the best way of growing Strawberries on railway embankments, as the whole ground is thus covered with them; and the fierce sunshine, though intensified by the slope of the ground, cannot burn the roots. Could the sewage of villages or towns but be made to trickle down these slopes beneath the foliage, what magnificent fruit might be gathered by the ton from such places. With a slight admixture of soil, and a fair supply of sewage or clean water, all things are possible in the way of fruit-growing on the sides of railway embankments; and as a sign-post to point the way, and an example which is worth a thousand arguments, the Strawberries just alluded to, seen on the North-western Railway, deserve a passing notice.—D. T. FISH.

Apple-blossom Maggot.—I have sent you some Apple-blossoms, at the base of each bunch of which you will find a small red maggot which, in some instances, has worked down into the wood. Nearly all my young trees have been attacked by this maggot, and most of the bunches of them are entirely destroyed. One tree in particular, which was covered with bloom a short time since, now presents nothing but a mass of withered and decaying petals. I fear my whole crop of Apples is gone, and, what is worse, that the growth of the young wood will be prevented. In some instances the maggot has attacked the ends of the young shoots as well as the flowers. Can you inform me if this pest is common in gardens, and if there is any remedy for it? I never saw it before.—AMATEUR, Warrington. [The insect in question is a small moth, named *Laverna vinolentella*. Mr. Stainton, who knows this tribe of insects better than anyone else, informs us that he never met with it himself until two years ago, but Mr. Gregson had previously observed it, and had detected the larva in the bud as early as February and March. It is more difficult to suggest a remedy.—A. M.]

A Place of Figs.—It would be hazarding little to say that the Fig tree is the main prop and support of Smyrna, and that its fruit, fresh or dried, furnishes the chief pabulum of her people's prosperity. The Fig, in every phase, from imperfect to perfect ripeness, “with jacket on,” or smothered in sugar, or neatly packed in drums for exportation (in which labour most of the adult population seems employed), meets the eye everywhere. Without entering into statistical details unsuited to this notice, suffice it to say that this peculiar industry gives constant and profitable employment to thousands of the population, and it is literally “by their fruits” that we know the Smyrniotes. This really constitutes the chief trade of this bustling and busy little city, netting a royal revenue annually for “Giaour” Ismir from the remote infidel on the banks of the Thames or Hudson.—T.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Dew-like Drops on Vine Leaves.—“S.” may consider the dew-like drops which hang upon his Vines in the morning a sign of vigour and health. The reason he does not see them in his other Vineries is, probably, because they are kept at a higher night temperature. If he gives air early in the morning, gradually increasing the amount as the temperature rises, he will find that the dew drops evaporate gradually without causing any damage whatever.—J. S. W.

Varieties of Damsons.—A neighbour, who now and then pays a visit to my orchard, tells me that my Damsons are not of the right sort. Is there more than one kind?—J. B. [There are several sorts of Damson with black fruit cultivated in England, such as the Common Black, with smooth spiny branches; Royal Damson, similar to the Prune Damson, but said to be larger; and the Shropshire Damson, with smooth branches, but not spiny. These are much alike in figure, but they differ a little in size, and possess different degrees of merit. This latter quality, however, depends upon the manner in which the tree has been propagated, the soil and situation in which it grows, and the health and vigour of the tree itself. Damsons raised from suckers and planted in hedge-rows, or grown among Nut bushes, or crowded among and under other trees, can never be expected to produce such fine, thick-fleshed, high-flavoured fruit as those which are grown upon sound healthy standards, in proper situations, unencumbered with coarse strong-growing trees.]

HECKFIELD.

ON the northern border of Hampshire, close to the parish of Eversley, now linked in men's minds with the name of Charles Kingsley, stands Heckfield, the seat of Viscount Eversley, one of those places the gardens of which are interesting to every horticulturist. Heckfield, though not so large as its neighbouring estates, Bearwood or Strathfieldsaye, nevertheless possesses certain characteristics that render it specially noteworthy; and, among these, one of the most important is its beautiful terrace-garden, in which modern flower gardening is well and skilfully carried out. It bears, also, a great name as a fruit-producing place; its grounds, which are well wooded and finely undulated, contain pretty lakes, noble trees, and extensive and well-kept lawns, here and there ornamented with clumps of Rhododendrons and other choice shrubs. On the east side of the terrace-garden the beds are arranged in separate blocks, in the centre of each of which is a large vase; whilst, on the north side, is a double line of pattern beds, and large raised oval ones in the centre. These raised beds and vases are, in summer, masses of floral beauty; whilst the rest are what are termed carpet beds, in which succulents in great variety are used, and many plants not commonly found in flower beds. In winter ornamental shrubs are substituted for flowering plants, and these, together with some of the hardier kinds of succulents, maintain a certain amount of freshness all through the dull season, and even on to the end of March, when they are removed to their summer quarters. In the neighbourhood of the lakes sub-tropical gardening is carried on to a small extent, and with successful results, that style of planting being better suited for such situations than trimly-kept beds, such as those just described. The Douglas Fir and other Coniferous trees thrive well at Heckfield, which, in a few years will possess many grand specimens of that class of evergreen vegetation. At the eastern extremity of the terrace-garden are two notable examples of the hardy Palm (*Chamærops Fortunei*), each about 9 feet in height, and as much in diameter. These were planted out about ten years ago; and, although they have had no protection, are in perfect health, and are even, as Mr. Wildsmith informs us, bearing fruit—that is, one of them, for the other is a male. From seeds thus produced in former years young plants have been successfully raised. Heckfield has always been famous for the production of Grapes, eight large houses being devoted to their culture; three are filled with Peaches, and from these are annually taken splendid crops of fruit. The Grapes in the earliest house are ready for cutting about the end of April, before the supply of Lady Downes in the fruit room is exhausted; and thus Grapes are fit for table here all the year round. The house in which these late Grapes are grown presents a fine sight in October, when they are fully ripe, and hanging thickly all over it. It is span roofed, and the rods are carried right over the entire span, which is some 30 feet in width. Some of the finest and best-furnished bunches of Lady Downes, perhaps ever seen, were cut from this house last year. In order to secure that perfect maturity which is held to be so essential to the proper wintering of this fine late Grape, additional heat power has just been placed in the house. The Grape room forms quite a feature at Heckfield, 2,000 bunches being capable of being stored in it at once, and kept in perfection often for four or five months at a time. All that is required is a dry temperature and an occasional inspection to ascertain whether or not all is going on properly. The borders and walls of the kitchen garden are well stocked with healthy trees. The Peaches especially are in excellent condition, and promise to produce abundant crops. Their blossoms are protected by means of a thin unbleached hemp covering, attached to rollers, as at Frogmore, and, being in long lengths, when let down it forms a close and efficient covering, and one which is very durable. The trees are dressed yearly with the usual mixture of soot, soft soap, tobacco-water, and lime, an application which can be made of a lighter or darker tint by adding a little more or less soot. Early Potatoes and Asparagus are forced in brick pits on beds of 2 feet deep of leaves put in dry; for surface-heat 2-inch pipes are employed. Although no dung is mixed with the leaves they soon generate sufficient warmth.

VIEW IN THE GARDENS AT HECKFIELD.

THE FLOWER GARDEN.

SPRING-FLOWERING PLANTS.*

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

THE month of April has been remarkable for a long continuance of dry easterly winds, with a hot sun prevailing during the day. On seven mornings only was the thermometer below the freezing point, the lowest markings being on the 13th, 14th, 19th, 20th, 22nd, and 24th of the month, when 28°, 31°, 29°, 30°, 25°, and 30° were respectively indicated. The highest morning temperatures were on the 1st, 2nd, 25th, 27th, 28th, and 29th, when 43°, 43°, 43°, 44°, 43° and 48° were shown. I have stated that April has been exceedingly dry—only at the beginning and towards the end of the month were slight showers experienced; but none of them were of that warm and genial nature characteristic of April. Up to the 15th arborescent vegetation was considerably behind, but it advanced rapidly after that date, evidently hastened by the strong sun-heat which prevailed, and the moisture existing in the ground from the quantity of melted snow which must have been absorbed during the past winter. On the 1st of May, 1874, vegetation was in advance of many former years; while, on the 1st of the present month, vegetation did not appear to be more than ten days behind that of last year, and, therefore, it is now fully up to an average season. On the 1st of May, Apples, Pears, Plums, Geans, the perfumed and double-flowering Cherries, were in perfection; many expanded flowers were also seen on the Horse Chestnuts and Lilacs, particularly in warm sheltered situations. The Hawthorn (*Cratægus oxyacantha*), although in flower on the 1st of May last year, did not open its first flowers on the same tree before the 10th inst. Appended is a list of the open-air herbaceous and Alpine plants, chiefly flowered on the rock-garden during the month of April, and arranged in the order in which they came into bloom. The past winter has been particularly favourable for such an arrangement, as it gives the precise succession more correctly than could possibly be obtained during a season when plants have not been so thoroughly rested as they were during the late winter. After a mild season, a correct succession could not be so much depended on, as many plants are often in a growing state during the late autumn or winter months. On the 31st of April, about 250 species and varieties were counted in bloom on the rock-garden. The list appended does not include all these, as numerous species and varieties of the genera *Narcissus*, *Saxifraga*, *Aubrietia*, *Primula*, *Alchemilla*, and *Carex*, besides many of a minor description, possessing comparatively little interest, as regards either flower or foliage, are necessarily omitted, as well as varieties which come into flower at the same time as the typical species. The list contains the remaining species of the thirty kinds selected for annually recording their periods of blooming, and which have been mixed up with the general list since the beginning of the year, although several were not grown on the rock-garden. The last plant of the selected series is the Crown Imperial (*Fritillaria imperialis*); it came into flower on the 18th of April, while last year it was in bloom on the 22nd of March, showing that in the case of this plant we were at that date (18th April) twenty-six days behind its time of flowering last year. My object this year for deviating from the ordinary selected thirty species, beginning with the Snowdrop and ending with the Crown Imperial, was chiefly to afford information to those amateur cultivators of Alpine and rock plants, who wish to grow a succession of plants so as to have some of them in bloom during every month in the year. It will, therefore, be my endeavour to make this list, and the dates of flowering, as correct as possible, confining my observations chiefly to plants of general interest. In my previous reports, I alluded to several Coniferous trees, as being very much browned from the effects of the late winter frosts, and the hot sunny days which were so prevalent afterwards. This browning is now showing very distinctly on several other kinds, such as the *Taxodium sempervirens*, *Abies Hookeriana*, and on many species of the genus *Pinus*, particularly the *P. Lambertiana*, *P. Strobus*, *P. excelsa*, *P. tuberculata*, *P. monticola*, and on many plants of

the Scotch Fir, *P. sylvestris*. It is remarkable to observe the common *Laurustinus*, now covered with flowers, the frost of last winter apparently having had no bad effects upon it. During some past winters, when the frost was less severe, including the winter of 1860-61, *Laurustinus* were entirely destroyed. Their preservation last winter may be accounted for by the wood being more thoroughly ripened during the previous autumn than usual.

ROCK PLANTS AT HEATHERBANK, WEYBRIDGE.

MR M'NAB's interesting account of the Edinburgh rock-garden, and "Salmoniceps's" remarks, have induced me to send you a few notes on our rock and root-gardens at Heatherbank. In the root-work are three plants of *Azalea mollis*, from Van Houtte, rose-buff, buff-rose, and orange-buff, each with from twenty to forty large clusters of flowers, which are individually much larger than those of the old Ghent Azaleas. We have also *Andromeda angustifolia*, with its white flowers clustered along the stem; *Linnaea borealis*, with its dense masses of delicate young green leaves and pretty little trumpet flowers; *Gaultheria procumbens*, which seems perfectly happy when forcing its growth between the bark and wood of the stumps, and, thus circumstanced, produces berries of unusual size and brilliancy.

* Read before the Botanical Society of Edinburgh, May 13, 1875.

In a cave on the north side a great clump of the Oak Fern looks as beautiful as it did in its Highland home, whence I brought it. In the rock-garden we have the *Erythronium giganteum*, with four large flowers on a stem, and in colour a beautiful pale primrose with bright yellow centre; *Cypripedium pubescens*, *C. arietinum*, small, but very pretty; *C. japonicum*, about to open; strong heads of *C. spectabile*; and some others of the Lady's-slipper family, not showing bud yet. *Aquilegia glandulosa*, from Forbes seed, is now in great beauty, as are also *Trollius asiaticus*, *Narcissus triandrus*, *Gentiana verna*, yellow Alpine Poppies, and *Phlox setacea*. Our large clump of this *Phlox* has one drawback—it is so attractive to our cats as a sleeping place that it is always sunk in the middle like an ill-made bed. We have, moreover, a great bed of *Primula japonica*, with about 100 heads of flower out; our plants of it stand closely together, which does away with the coarse effect of the foliage; the bed was fringed with a double row of the old *Primula cortusoides* (not *amœna*), which is now nearly over, but, when in perfection, it had a pretty effect. A large clump of *Camassia esculenta*, with its beautiful blue flowers, is just coming out. I might add to this list, but the above are the chief favourites now in bloom, or nearly so. Our success with Lilies in the root-work last year has led us to make more clumps of many species, and, so far, they are most promising; *L. auratum*, though young, has stems which measure 2 inches and more in circumference already. In the cool Lily house, in a pot, is a lovely bloom of *Cyclobothra cœrulea*, and many other *Cyclobothras* and *Calochortuses* are in bud.

GEORGE F. WILSON.

SPRING GARDENING AT BELVOIR.

THE spring flowers at Belvoir are arranged in sheltered openings on the well-wooded slopes on which the present castle stands, and have been very attractive during the past few months. When we saw them a week ago, the beds, borders, terraces, and scrolls were masses of soft harmoniously-blended colours, the effect of which was considerably heightened by the tender herbage and woodland beauty by which the spring gardens are surrounded and sheltered. When the flower garden is surrounded by trees and shrubs, as in this instance, charming effects of light and shade are obtained, especially late in the afternoon and evening, as the sun sinks towards the horizon, and his rays stream across masses of golden Madwort, lilac-purple Aubrietia, crimson Polyanthus, and delicate blue Forget-me-nots. There is one important feature which distinguishes the spring gardening at Belvoir from that at most other places which we have seen, and that is the artistic manner in which the colouring of the beds and terraces is softened off into the margins of rocky pathways and shrubby borders; or, in a word, the shrubby margins lose themselves in the glowing colours of the parterre, while the richness of the flower garden itself seems to melt away in the luxuriant freshness of the over-hanging trees and leafy undergrowth on all sides, leaving no trace of that harsh and unpleasing line which so often separates the trim neatness of the flower-garden from the equally enjoyable woodland walks and leafy tree-shade. One of the latest additions to the already ample beauties of Belvoir is the Duchess's garden—an irregular and extensive plot scooped out from the well-wooded slopes, sheltered on all sides by well-developed forest trees and ornamental shrubs, fringed with feathery Birch and Yews, and now jewelled with thousands of the most beautiful hardy flowers, the soft, yet rich, colouring of which no combination of Geraniums, Calceolarias, or other summer bedding plants can excel. It was a happy idea which induced Mr. Ingram to enamel the fresh green turf of this sheltered glade with spring flowers, the position being precisely similar to that which Nature herself selects for them. At the time of our visit much of the beauty of early spring flowering plants had fled; but, if we missed the delicious perfume of half-an-acre of Violets, the regal purple and gold of the vernal Crocuses, or the ruby, amethyst, or pearly colouring of the oriental Hyacinth, we obtained glimpses of the later flowers of spring, or rather of those "earth stars" which connect spring with early summer. Let us now look at spring gardening as practised so successfully at Belvoir, from a practical point of view, and note the means by which the rich and harmonious combinations of colour which are to be seen there, have been obtained. The most beautiful beds and borders at the time of our visit were those planted with well-known spring-blooming perennials, such as Lilac, Aubrietia, Golden Madwort (*Alyssum*), blue Forget-me-nots, and snowy-white Arabis; and these were here and there further enriched by the introduction of crimson-tinted golden-eyed Polyanthus, and bedding Pansies, of nearly all shades, from golden-yellow to blue, maroon and velvety bluish-black. One of the serpentine-terraced beds struck us as being exceptionally fine; it consisted of a line of the dwarf Belvoir Wallflower (which, for spring bedding, is decidedly the best), then a broad belt of blue Myosotis,

then the soft lilac-purple Aubrietia, in front of which was a broad margin of the golden-green Stonecrop (*Sedum acre*), jewelled with panel-like masses of Aubrietia, which gave a most attractive appearance to the whole arrangement. A bed of the star-like golden-flowered *Doronicum caucasicum* on a dense carpet of blue Forget-me-nots was remarkably pretty, as also were some tastefully-arranged beds of double crimson and white-flowered Daisies. The luxuriance of the great-leaved Saxifrage (*S. crassifolia*), planted in beds and borders, partially shaded by trees, was wonderful—indeed, some of the flowering stems—carrying clusters of soft rosy flowers—were nearly a yard high, and the development of the fresh green foliage was equally remarkable. Strong tufts of the *Veratrum nigrum* were scattered here and there on the fresh turf, in positions where it proves to be most attractive, its broad plaited leaves having quite a Palm-like appearance before the tall flower-stems are produced. Turn where one would, the variety of plant forms and the numerous shades of soft colouring, were most pleasing and enjoyable. The position of the Duchess's garden is one of the best that could have been selected, and the woodland scenery, as viewed from the rocky pathway above it, is most charming. To a real lover of plants the margins of these pathways and shady woodland walks afford a treat, bejewelled, as they are, with the rarer Alpine and herbaceous plants, such as Irids, Sedums, Saxifrages, Wallflowers, Bluebells, Forget-me-nots, Primulas, and curious or showy flowering bulbs. In one bed we found some very vigorous specimens of the yellow-flowered *Primula verticillata* blooming profusely, and we deem the fact worth mention here, for it is not generally known that this fine yellow Primrose and its crimson-flowered ally, *P. japonica*, are admirably adapted for naturalising on moist sheltered banks in the Alpine or wild garden. In the kitchen garden we found an enormous specimen of the old Chinese tree-Peony profusely covered with its deliciously-fragrant rosy flowers, and fully 6 feet in diameter.

B.

Beauty on Railway Embankments.—I have often seen many pretty plants on railway embankments, but never met until last week with a railway embankment converted into a bank of Primroses intermixed with Cowslips. The sight was perfectly fascinating. If I remember rightly, this charming bank was almost within sight of Stockport. Are they, I should like to ask, natural productions; or did some generous lover of Nature sow seeds or plant Primrose plants there? Either way, the flowers—and such flowers as Primroses in quantity—on the sides of the iron way, are well placed. We have hundreds of wild flowers, Grasses, succulents, Heaths, Mosses, and other plants that could be established in such places. On the shady sides, Ferns would find congenial homes. We have only to take the initiative, insert a few seeds or plants, to show Nature what is desired, and she will not fail speedily to further our endeavours. Would it not be worth while to have some kind of association to take in hand the covering of railway embankments with plants, and their conversion to utilitarian purposes?—D. T. FISH.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

German Asters Sown in the Open Ground.—Like many more I have unthinkingly followed the practice of sowing these in a frame, or in pots, and then transplanting them, but I found that the transplanting season falling, as it did, at the busy bedding-out time, was often overlooked and the seedlings neglected. I, therefore, now sow in the open border where they are to stand, and prick out as they need it. In this way I get good flowers.—N. H. P.

Mimulus in the Open Ground.—Since I wrote the other day (see p. 403) about Clapham's strain of *Mimulus*, I have put some 200 plants of them out of doors, where they promise to grow strongly and bloom profusely. The fierce winds of the past week have been bravely withstood, and every one of them is now in bloom, all being prettily and singularly varied both in markings and colours.—A. D.

Double Scarlet Geum.—This beautiful hardy perennial, though much superior to the single Geum, does not seem to be well known. It is a most continuous bloomer, flowering from spring till late in autumn. If several of the flowers are tied together in a bunch no double scarlet Geranium can surpass them in effect. With me this plant never seems to increase in size so as to admit of division, but that does not matter, as it produces seeds in abundance, and they come up freely if sown in the open garden.—G. F., Northumberland.

Viola pedata.—After growing this for three years, I have not been able to induce it to flower. Why it should be so reluctant to blossom I am unable to say, and should be glad to be enlightened on the subject. It is in a 10-inch pot, which contains seven strong plants raised from seed three years ago. Some others, I hear, have been equally unfortunate. Do seedling plants bloom, or is it a fact that flowers can only be obtained from plants propagated from imported stock.—ALEX. DEAN.

A Wood full of Wild Hyacinths.—I have often heard of a wood full of this flower, but never till the other day, in the neighbourhood of Sheffield, did I see one. There you could not see the ground for Hyacinths, the surface being wholly and altogether hidden by them, and this by plants which overran the wood into a meadow close by and possessed it. The area over which the plants were spread was not very wide, but it was crowded with these beautiful flowers as far as it went, and was a magnificent argument in favour of bedding out in broad masses of one colour.—D. T. FISH.

THE LIBRARY.

DOLIVOT'S SYSTEM OF TRAINING.*

NEARLY half-a-century ago the system of training certain kinds of fruit trees so that the branches were led to assume a pendent position was practised in this country, and even now the fruit trees which margin the compartments in front of the terrace at Frogmore, as well as those along the sides of the centre walks, are trained in this manner, being carried up with clean stems to the top of a trellis, and thence again to the ground. Notwithstanding this apparent subversion of the laws of Nature these trees continue year after year in perfect health, and bear abundant crops of fine fruit. English books on fruit culture have, however, been silent, or nearly so, as regards the alleged advantage of this mode of procedure; England, indeed, is apt to show its conservatism when the utility of any old-established custom, that has answered the purposes of our forefathers, is called in question, and it is more than usually liable to do so when asked to adopt some new system, the value of which has not been stamped with the die of practical experience. It has been left, therefore, to a French writer to take the matter up. M. Dolivot, in doing so, has shown a capacity for methodically arranging and expressing his ideas that may, in a measure, be traced to his professional training as a lawyer; but we must none the less lose sight of the plain facts which both he and his assistant, M. Maître, place at our disposal. The advantages which the author alleges are to be derived from the system

Frame for young tree.

Tree after one year's growth.

Tree after two year's growth.

trees, and consequently an increase in the productive capacity of the land; thirdly, simplification in the operations of training and pruning; fourthly, resistance of atmospheric influences; fifthly, preservation of the trees against spring frosts, and great opportunities of sheltering them from bad weather; and, sixthly, perhaps the superior quality of the fruit. M. Dolivot's system, in a great measure, explains itself by the illustrations we are enabled to publish. The stem of the young tree is provided with a support, surmounted by a circular frame-work, whose circumference is kept in position by a single bar of wood, the remaining radii or spokes of the circle to the number of six being supplied by iron-wire. To these the branches of the tree are fastened horizontally, and are then allowed to fall to the ground, any refractory branches being kept down by leaden weights until they are thoroughly accustomed to their new positions, and in this they are, in some

Graduated column, incomplete.

cases, assisted by means of supports fixed in the ground perpendicularly below each branch as it bends over the upper hoop. At a slight distance above the ground, a second hoop is placed, and round this, as they reach it, the trailing branches are led; the hoop being steadied in its place by four shoots which have been provided for on the lower part of the main stem opposite to it. This form M. Dolivot calls the "simple column," and the rest are merely elaborations of it, for it is easy to see that by carrying the stem up, and by the use of an additional hoop, the number of stages or tiers may be increased to three or even four, although the former number appears to be the limit attempted by the writer. One form, which is called the "graduated column," is so peculiar—we may say fantastic—that it requires special allusion to be made to it, and we therefore give illustrations of it. It has the disadvantage of occupying quite as much space as an ordinary pyramidal tree, being comprised of six wings and three tiers

which he advocates are—first, rapid fructification, especially in the case of old trees, that are apparently past bearing; secondly, economy of the space that can be devoted to fruit

* "Les Arbres Fruitiers à Branches Renversées." Par A. E. Dolivot, Grenoble.

of branches. The subject to be operated on should be a well-established young tree, the stem of which should be cut 4 feet from the ground, and seven branches secured. The uppermost branch is kept to continue the stem, and the remaining ones are trained horizontally until they reach the outer angle of the frame, when they are brought into a perpendicular position. The other stages are produced in a similar manner. No one can fail to admire the ingenuity displayed in the creation of the various forms of which the author gives examples in his book, nor the thoroughness with which he has discussed the whole matter within the limited space of 200 pages. Without going so far as the author in his very confident assertions respecting the utility of his system, this much may be said—it is based upon principles that are perfectly sound, if not universally adopted. Under certain circumstances, any method of training that tends to counteract over-luxuriance must necessarily promote fertility. Of this we have had ample proof in the processes of root-

Graduated column, completed.

pruning, ringing the branches, and summer pinching. Fanciful though the modes of training recommended in this book may be, they will doubtless have a similar effect; and, under some conditions, may be safely adopted, especially by those who have only a limited space at their disposal, but more time to attend to an elaborate system of training than is generally the case with those engaged in fruit culture on an extensive scale.

VAN HOUTTE'S "FLORE DES SERRES," VOL. XXI. PARTS I., II., and III. of this volume have reached us, and contain the following plates, many of them, we regret to see, reproduced from other works:—Plate 1 represents *Æchmea cœlestis*, a rather dull-coloured Bromeliad, producing a spike of brown and pale blue flowers. Plates 2 and 3 show a beautifully executed portrait of *Oncidium crispum*, with large brown flowers, having a deep yellow centre. It is a native of Brazil, and was figured by Loddiges in 1854, and also since by Lindley in the "Botanical Register," and by Hooker in the "Botanical Magazine." Why, therefore, does Mr. Van Houtte waste valuable space by figuring plants so frequently

illustrated in other works when newer and less-known species would be so infinitely more acceptable to horticulturists, so many of whom are subscribers to his beautiful work. In plate 4 we are shown the handsome Composite *Gaillardia amblyodon*, one of the new annuals introduced last year from Texas, we believe by Mr. Thompson, of Ipswich. Plate 5 represents *Masdevallia maculata*, a distinct and handsome species, producing flowers, the upper portion of which is golden, the lower deep purple, splitting into two curious green tails. Plate 6 shows the beautiful, and but little known, *Pittosporum crassifolium*, reproduced from the "Botanical Magazine." The flowers are deep crimson, resembling those of *Escallonia macrantha*. Plates 7 and 8 represent the handsome Palm, *Hyphæne thebaica*, as seen growing in Egypt and Abyssinia, where it is indigenous, and plates 9 and 10 two heads of the curious bearded Maize or Indian Corn, somewhat resembling in shape and appearance a bundle of the fragrant Indian Couscous Grass. In plates 11 and 12 is most faithfully depicted the beautiful Maple known under the name of *Acer polymorphum palmatifidum*, of which, unfortunately slugs and snails are so fond that they strip its branches of every leaf, when in a young state, if they once find them out. Plate 13 illustrates the curious *Mammillaria senilis*, or Old Man's Head Cactus, resembling a head of snow white hair, with prickles through it. Plate 14 is a portrait of the well-known hardy Turn-cap Lily, known as *Lilium chalcedonicum*. Plates 15 and 16 represent *Tydaea Belzebuth*, one of the many handsome seedling varieties raised in Mr. Van Houtte's establishment, and plate 17 *Pilocereus Dantwitzii*, a singular pillar-shaped Cactus, covered with white hairs, which give it a strange appearance, well thrown up by the dark green background against which it is figured in this plate. Plate 18 is a portrait of a prettily-spotted *Gloxinia*, named *Ami Thibaut*, raised by Mr. Van Houtte. Plates 19 and 20 represent several specimens of *Thrinax* as seen in their native habitat. Plate 21 accurately represents the curious and ornamental little orange-berried *Nertera depressa*, trailing over a bank, and profusely covered with its pretty fruit. Plate 22 is said to represent *Petunia intermedia*, but seems to me to much more resemble one of the *Nierembergia* family, with deeper-coloured flowers than those of *N. gracilis*. It is said to be a difficult plant to cultivate, only succeeding when grafted on *Nicotiana glauca*; it is a native of Rio de la Plata, and, though it will succeed out of doors during the summer months, it usually succumbs to the damp of our winters. Plates 23-24, though beautifully drawn, and coloured with exquisite delicacy, seem to but poorly represent, at least as far as size is concerned, the Rose, *Paul Neron*, of which they profess to show a portrait. The individual flowers of this Rose rank, as is well known, among the largest in cultivation.

W. E. G.

The Lovers' Garden.—There is a land, a delightful country, which would in vain be sought for on the waves of the sea, or across the lofty mountains. In that country, the flowers not only exhale sweet perfumes, but intoxicating thoughts of love. There every tree, every plant breathes, in a language more noble than poetry, and more sweet than music, things of which no human tongue can give an idea. The sand of the roads is gold and precious stones; the air is filled with songs, compared to which those of the nightingales and thrushes, which I now listen to, are no better than the croaking of frogs in their reedy marshes. Man in that land is good, great, noble, and generous. There all things are the reverse of those which we see every day; all the treasures of the earth, all dignities crowded together, would be but objects of ridicule, if there offered in exchange for a faded flower, or an old glove, left in an Honeysuckle arbor. But why do I talk about Honeysuckles? Why am I forced to give the names of flowers you know to the flowers of these charming regions? In this country no one believes in the existence of perfidy, inconstancy, old age, death, or forgetfulness, which is the death of the heart. Man there requires neither sleep nor food; an old wooden bench is there a thousand times more soft than eider-down elsewhere; slumbers are there more calm and delicious, constantly attended by blissful dreams. The sour Sloe of the hedges, the insipid fruit of the Bramble, there acquire a flavour so delicious that it would be absurd to compare them to the Pine-apple of other regions. Life there is more mildly happy than dreams can aspire to be in other countries. Go, then, and seek these poetic isles! Alas! in reality, it was but a poor little garden, in a mean suburb, when I was eighteen, in love, and when *she* would steal thither for an instant, at sunset! So loved I a little shut-up garden.—ALPHONSE KARR.

The Wistaria and Bees.—It has been thought that the flowers of *Wistaria sinensis* were fatal to bees; but Mr. Meehan, thinks the death of bees frequently found lying around this plant must be due to some other cause. He says that he has himself often seen hundreds of dead bees under this shrub, and formerly shared the popular idea that the flowers poisoned them; last year, however, he observed that many bees visited the flowers without apparent injury.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Planting Celery.—Early-sown Celery should now be put out; if the trenches have been prepared beforehand, as advised some time back, run the hoe over the surface to destroy any weeds that may be vegetating. Give the plants a good soaking with water before moving them, and, if they have been treated as directed, by being put out in a nursery bed 3 or 4 inches apart, they will now be in fine condition; remove them with as many roots as possible, and as much soil as will adhere to them. In moving Celery plants, there should never be occasion for the now almost obsolete practice of cutting off or shortening a considerable portion of the leaves at planting time; on the contrary, Celery, more than most crops, should never, throughout the whole course of its cultivation, from the time the plants appear above ground, until they are fit for use, receive a check more than is inseparable from transplanting them, even when that operation is performed with care. If the trenches have been prepared for double or treble rows, put the plants in a foot apart each way; if for single rows, 9 inches between each plant will be sufficient for ordinary purposes. In making the holes, use a planting trowel, and see that they are large enough to admit the roots without crushing them together; give each row a good watering as soon as planted. Celery costs more in manure and attention, to grow it well, than most vegetables, and it is worth while to treat it in a way calculated to produce it in good condition.

Leeks.—When indifferently grown, these are little better, for the purposes for which they are required, than Onions. To obtain the peculiar mild flavour which Leeks possess when large and freely grown, the plants must not be allowed to become stunted by being too close in the seed-bed; to prevent this, thin them out so as to leave them 6 inches apart.

Tomatoes.—These should now be planted against all vacant places on walls; do not make the soil in which they are to grow too rich, or it will induce the production of shoots and leaves rather than fruit; if, afterwards, the plants appear to require a stimulant, it can be given in the shape of manure-water; leave the soil hollowed out round the stems so as to hold plenty of water, especially until they have become established. Train them to the wall, either with shreds and nails, or by means of ties, so as to expose them fully to the sun. Where there is no space on walls at liberty Tomatoes may be grown in 9 or 10-inch pots; select a warm, sheltered, sunny place for them, and plunge the pots in the soil, keeping the plants through the season well thinned out and secured to sticks, so as not to be broken with the wind. It is necessary to confine the roots in pots when the plants are thus placed in the open ground, where, in an unusually wet season, too much growth for the production of fruit would be the result if the roots had unlimited scope.

Thinning Onions.—Spring-sown Onions should be thinned before they get too large. Take advantage of the soil being moist after rain to do this. If it is hard and dry, the limited quantity grown by most amateurs may be watered, so that the removal of any need not injure those that remain, which often happens, when the ground is hard. As to the distance the plants are left apart in thinning, account must be taken of the kinds grown. Large kinds, such as Rocca or Nuneham Park, require double the room necessary for small varieties, like Danvers or James's Long Keeping. If it is desired to grow well-developed bulbs of the large-growing kinds, these should be thinned so as to leave them 8 or 9 inches apart in the row; the smaller-growing, later-keeping sorts will not require more than half that room. Where some are required for pickling, a portion of the smallest-growing kinds may be left not more than an inch apart; or, unless they have come up very thickly, without thinning at all.

Gooseberries.—If the means advised in the winter of putting lime on the soil round the stems of the Gooseberry bushes as a preventive against caterpillars was carried out, little injury from these may be looked for; but, in the case of any bushes that were affected last year without this precaution being taken, their reappearance may now be expected; when any can be found they should be destroyed at once, or they will spread and quickly denude the trees of their leaves, spoiling the present crop, and doing serious mischief by weakening the bushes for another season. A dusting of dry powdered lime sprinkled over the affected trees will, if fresh and caustic, destroy many and cause the rest to fall off on the ground, where they must be killed, or they will again crawl upon the trees. This should be done when there is an appearance of some dry weather, for, if wet, the lime will be washed off before it has had any effect. The most certain method for destroying these caterpillars is by using a mixture of white hellebore (finely ground) and whitening, in proportions of one pound of the former to four or five of the latter, mixing the whole well up and applying it with an ordinary tin flour dredger, first wetting the leaves thoroughly with

the syringe; the powder thus sticks to the foliage, and the caterpillars, feeding, as they do, on the edges of the leaves, swallow that which adheres to them, and it quickly kills them; in five or six days not a grub will be found alive, when the trees can be well syringed to remove the powder from the fruit and leaves. The only objection to the use of this mixture is that the hellebore being poisonous, care must be taken that it is all washed off before the fruit is used.

Flower Garden.—Dahlias should now be planted. Amateurs who set a portion of ground apart for them should on this grow the best prepared plants, which will be those that have been struck from cuttings, these being less liable to get crowded with shoots, and consequently produce finer flowers than plants that are obtained by dividing the old roots. Where fine flowers are required, the plants should stand 6 feet apart every way. The ground can scarcely be made too rich; they should be well watered at the time of planting out, and at once secured by good stakes; but the stems should not be tied too tightly, so that their subsequent expansion may be allowed for. Round the stems, for a foot, cover the surface an inch thick with sharp sand, so as to make it less agreeable for the slugs to travel over. A little Wheat-chaff, or hard straw chopped up half-an-inch long, does much to impede their movements, for they object to travel over anything that sticks to them, and this is the case with these substances even when wet. The best of all for the above purpose, where they can be obtained, are the short clippings of bristles from brushmakers. Wet or dry, these are equally effective, and are too sharp for slugs to attempt to cross. Lime and soot dusted round the plants will stop the movements of slugs whilst dry; but, with moisture, it soon gets crusted, after which they will pass over it, and repeated applications do harm to the plants. The same material can with advantage be used round any other plants molested by slugs. Iresines, Coleus, Alternantheras, and similar tender plants, may now be planted out. Amateurs who may be making a first attempt at carpet bedding should bear in mind that the effect produced by this style of flower gardening is, in a great measure, dependent upon the different subjects employed being planted very close, so as at once to all but cover the surface, an even dense clothing to the ground being essential to give character to the arrangement. It will thus be obvious that a greater space should not be devoted to this kind of bedding than can be furnished well. The same may be said of the arrangement of larger-growing, handsome-leaved subjects, inappropriately termed sub-tropical. Although, in this "leaf-gardening," it is necessary to allow each plant sufficient room to develop perfectly, yet, they should not stand so far apart as to give them a thin straggling appearance—due allowance, of course, being made at the time of planting for the after-growth they may be expected to make in an average favourable season. Where this style of gardening is attempted, either on a large or small scale, there should always be kept in reserve a sufficient number of plants to fill up blanks caused by the failure of any of the more tender subjects employed, as a very few gaps spoil the effect of the whole arrangement. As the plants are put out see that all that require it are properly secured with sticks and ties; if the weather keeps hot and dry large-leaved specimens must be plentifully supplied with water, as any deficiency of this would tell on the foliage in a way that no subsequent attention could rectify.

Pits and Frames.—The earliest sown Melons will now be showing fruit, but none should be allowed to set until there is a sufficient number to give promise of a crop. Let the soil get much drier than usual before flowering commences; do not allow a quantity of weak, useless shoots to remain on the plants, but do not thin too much before the fruit has set. Melons are much more liable than they formerly were to go off through canker at the collar, especially when grown in pits and frames, with the shoots trained out over the surface of the soil. From the time the plants get fairly established in the soil care should be taken that, in giving water, none is allowed to touch the collar or the soil for 5 or 6 inches round the stem, and if anything in the shape of canker makes its appearance, which can easily be detected by the rough brown appearance the bark assumes near the base of the plants, all that can be done is from time to time to dust a little dry lime upon the affected part, which will sometimes arrest the progress of the disease and keep the plants alive until they have ripened their fruit.

Flower Garden and Pleasure Ground.

The present season, like many former ones, has shown that no advantage is gained by turning out tender plants into flower-beds earlier than the last week of May, unless it be in very favoured localities. In this neighbourhood the Grass was white and crisp with frost on the morning of the 17th, hail fell during the 19th, and the night was sufficiently cold to have injured such tender plants as Heliotropes, Coleuses, and others. It may now, however, be taken

for granted that Calceolarias, Zonal Pelargoniums, Verbenas, and similar plants, have been already planted out, and the putting out of the more tender varieties may now be proceeded with, such as Bouvardias, Lantanas, and Heliotropes, together with the various kinds of fine-foliaged or sub-tropical plants, and the placing out-of-doors of such plants when of considerable dimensions must be at once followed by careful staking and tying, and dwarf or trailing species should be rendered secure by being pegged down. Copious waterings must also be given should the weather continue dry, and it is of importance that this should be done as late in the evening as is practicable, or when evaporation may be supposed to be at its minimum. If it is administered in the morning or during the day, a large portion of the moisture supplied must necessarily be lost, as far as the benefit of the plants is concerned. A few plants, of each variety of which the various beds consist, should be retained in pots, for a time at least, as accidents sometimes occur, and a reserve force of this kind is often found to be useful. Some of the various kinds of variegated Pelargoniums, and other plants which are not of rapid growth, should about this time be planted in the reserve garden, with the view of affording an early supply of cuttings, thus obviating the necessity of taking them from the flower beds before they can well be spared for that purpose. Let the confusion, which is to some extent inseparable from the process of planting out, be set straight as soon as possible. Recently-formed plantations of Roses should be well attended to with water, and should also be mulched with manure. The young shoots are now, as is generally the case at this season, more or less infested with aphides, and the leaf-rolling caterpillar is also beginning to attack them. The latter must be picked off by hand or crushed by means of a gentle pressure of the fingers; and to destroy the aphides, diluted tobacco-water should be applied to the infested plants with a syringe, or they may be dusted with Pooley's Tobacco-powder during a calm evening and well syringed with rain-water on the following morning. Shrubberies are still gay with the various flowering shrubs. Lilacs and Rhododendrons have this season flowered most profusely, and, as soon as the flowers of the latter are decayed, the seed-pods should be carefully picked off and the plants should have one or two good waterings to enable them to finish their growth and to form flower-buds for another year. The young shoots of some Coniferous trees are not unlikely to be about this time attacked by a small but very destructive maggot, which, if not prevented, will inflict serious injury upon young plants of the *Pinus insignis*, the Douglas Fir, *P. Nordmanniana*, and others. Squirrels, too, are exceedingly destructive to all the *Pinus* tribe, and means should be taken to prevent injury of this kind if possible. Attend carefully to lawns, gravel walks, and drives; the weather has recently been favourable for the destruction of weeds upon gravelled surfaces of all kinds, and advantage should be taken, after heavy falls of rain, to roll them well the following day.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Roses.

Caterpillars are now found to be causing great destruction among young Rose-buds. They should therefore be looked carefully over, and all that can be seen destroyed. Afterwards the trees should have a good washing with the garden engine or syringe, mixing with the water aloes, quassia, and tobacco-water. Quassia I find best, both for destroying aphides and caterpillars. I use almost 4 lbs. of rough quassia chips in every 16 gallons of water. Of bitter aloes, 2 ounces to 6 gallons of water is sufficiently strong for Roses; tobacco-water I use as supplied by the vendors. Young growths of standard Roses will require tying up; otherwise, in stormy weather, the wind often breaks some of the best shoots. Briar Stocks, at this season, often throw up suckers, all of which should be carefully removed. They should be traced, and cut off at their source with a spade, the latter being held so as to cut from the stem, not towards it, as, in that case, the roots are apt to get injured. The late rains have beautified Roses greatly, and their vigour and beauty will be further increased by giving them a good watering with liquid manure; supplying each plant with about 2 quarts, as taken from tanks in the stable or cow-yard, watering it well in with clear water, so as to drive it down to the roots. When fine blooms for exhibition are required, large clusters must be thinned out well to one or two buds, and the plant should be mulched with cow-dung, and kept well watered and syringed, so as to maintain healthy growth, free from blight. In watering Roses for exhibition, soot-water may be used; put half-a-bushel of soot to every 10 or 12 gallons of water, and add about half-a-pint of this to every gallon of clean water. This, I find, improves the colour, both of leaves and flowers.—H. G.

Indoor Fruit Department.

Vines.—Inarching one variety of Vine on another may be successfully done now. Green wood unites to green wood much more

easily and quickly than that which is hard and brown. Young canes raised from eyes this spring should be used, and the growth should be from 3 to 6 feet or more in length, whilst the stock should consist of one of the side shoots, which has been pinched at five or six joints from the main stem. A leading shoot, which has been allowed to grow from near the bottom, will do equally well. It is an advantage to have the young Vines attached as near the base as possible, 12 inches being a very good distance. As the stock is generally much further from the ground than this, the pot containing the plant should be raised on a temporary wood stand to the required height. The process of inarching is very simple, and may be rapidly accomplished. A thin slice, about 2 inches in length, has to be taken off the two parts to be united, with a sharp knife; when this has been done the two cuts must be laid closely and neatly against each other, and then bound round with soft matting or Roffia Grass tight enough to keep them firm. In about a fortnight the union will be so far accomplished as to warrant the ligatures being loosened, and in another fortnight the matting may be removed altogether. If the union is not perfect by this time, the Roffia Grass should be left on until it is. The Vine in the pot must throughout be kept well watered, and, when the union is complete, the small cane in the pot should be cut away close to the bottom of the part connected. The part above this, if not very long, may be left on until the Vines are pruned and dressed in autumn or winter. The kind of stock is a matter of importance, as all are not equally suitable—certain varieties improve on other roots, while with others the reverse is the case. The Black Hamburgh is a suitable stock for many kinds, Muscat of Alexandria is another which seldom fails. Indeed, those which produce good fruit generally make good stocks. Muscat Hamburgh does well on the Black Hamburgh, whilst Royal Muscadine is a poor stock for most Vines; Black Prince and Burchardt's Prince are no better; Barbarossa (*Gros Guillaume*) produces more bunches on the Black Alicante than on its own roots. Inarching is not always necessary to increase the fertility of this Grape. In many places it does well on its own roots. Inarching is not always done with a view to improvement—it is often performed to hasten the fruiting of new varieties, and there can be no question about the utility of the operation for this purpose.

Pines.—The greater part of the Queens started into fruit in February will be ripe or ripening now; little or no water should be given at the root after the fruit begins to get yellow. As soon as the fruit is cut the ball must have a thorough watering to prevent the suckers from suffering. If space for successional plants be scarce, the Queen stocks may be packed closely together, after the fruit is cut, in some spare corner, to mature the suckers; successional plants which may be becoming crowded may then be thinned out to a distance which will admit of their free development.—J. MUIR.

How Flowers for the Sick Poor are Distributed.—Mr. S. Walliker, of Post-office Buildings, Hull, has lately written to the "Times" on this subject as follows:—"The work of collecting and distributing flowers for the sick and infirm poor is so rapidly spreading, and is productive of so much direct and indirect good, that you will perhaps permit me to give a few practical hints as to the commencement and the carrying-on of the work which have suggested themselves as the result of upwards of two years' experience, during which time about 30,000 bunches of flowers have been distributed among the poor of Hull. The system adopted here has been framed with the view of saving all possible trouble to those who send, as well as to those who distribute the flowers. A depôt was selected in a central situation convenient for the reception of flowers brought by rail, boat, or carrier; it is open all day, and some one is always at hand to receive the flowers and, if possible, to return the baskets and other packages by bearer, and trays about 2 or 3 inches deep, covered with galvanised iron netting, and filled with water, are kept ready to place the flowers in, so as both to refresh and preserve them. The ready sympathy of the local press was secured, and is still in active operation, and the public were requested to send flowers, made up in small posies, if possible, to the depôt. To assist the public, stout hampers, divided in the centre by an extra lid (the hampers cost half-a-crown each), with two printed leather labels, one bearing the inward, the other the outward address, are supplied to anyone who will undertake to collect and forward flowers. Small printed card circulars are at the same time sent to those who are likely to contribute to the baskets, advising them as to where they are kept and the days on which they will be despatched. A simple record of the date, the names and addresses of senders, and special remarks is kept, and the receipt of flowers is acknowledged by means of printed post-cards, only requiring the date and address to be written. The distribution here is not confined to the public institutions, but is made also to the sick, infirm, and aged poor throughout the town. To regulate the

supplies and prevent waste, printed lists giving the names of all the hospitals, workhouses, &c., and the names and addresses of all the district visitors and others who undertake to distribute to the outside poor, are prepared. These lists have seven columns. In the first, the greatest number of bunches each institution or person can dispose of is stated; the other six columns are for the days of the week. Some visitors cannot distribute flowers on certain days, and in those cases marks are printed in the respective columns opposite the visitors' names. These lists become valuable for statistical purposes and for comparison of year with year. The number of bunches, regulated by previous supplies, to be sent to each institution or person is entered on the list, and the flowers are sent out in covered baskets (to preserve their freshness and perfume) by a little lad in uniform (a half-time school-boy), who copies on a slip of paper, for his own guidance, the names and numbers. He is paid 3s. a week. When not busy he carries on his studies. During the winter months pots and pans containing Mosses and Lichens, Carrot-tops, Wheat-ears, and grains of Wheat, pots of bulbs, bunches of evergreens, &c., are sent out, so that there is never a week in which something is not done to cheer the poor, especially the sick, and to assure them of the loving sympathy which exists (too often latent, however) in the breasts of their well-to-do brethren.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

MAY 26.

At this exhibition, generally the best of the year, stove and greenhouse plants, Orchids, Ferns, and florists' flowers were all well represented. Pot Roses, from Messrs. Paul & Sons and Mr. Charles Turner were, as usual, excellent, and there was a good display of hardy flowers, among which may be ranked Messrs. Jackman's Clematises, of which we have already given some account.

Stove and Greenhouse Plants.—Superb examples of these came from Mr. Ward, Messrs. Jackson, of Kingston, and Mr. B. S. Williams. Mr. Ward had *Anthurium Scherzerianum*, furnished with over twenty bright scarlet spathes; the snowy white *Dracophyllum gracile*, 3 feet in diameter, and well flowered; the deep purplish-blue *Statice profusa*, fully 4 feet through; *Erica Cavendishi*, a dense globe 5 feet in diameter, and loaded with yellow flowers; *Hederoma tulipiferum*, *Azaleas*, and *Aphelexis macrantha purpurea*, all in beautiful condition. One of the most distinct and effective of all the plants staged in this collection was, however, an example of the deep orange-yellow-flowered *Azalea sinensis*, which was fully 4 feet in diameter, and a dense mass of brilliant flowers and tender young foliage. The colour of this *Azalea* is so vivid that the *Ixoras* beside it had quite a dingy brick-red appearance. Among the most distinct and effective of Mr. Williams's plants were the mauve-flowered *Bougainvillea glabra*, *Anthurium Scherzerianum* (with about thirty brilliant flower-spathes), *Medinilla magnifica*, two or three *Azaleas*, *Erica tricolor Massoni*, and *Aphelexis rupestris rosea*—all finely grown, and well flowered. Messrs. Jackson had a remarkably even and well-finished group, in which were splendid specimens of *Aphelexis macrantha purpurea*, *Boronia pinnata*, *Dracophyllum gracile*, *Pimelea Hendersonii*, *Statice profusa*, *Epacris grandiflora rubra*, *Hedera fuchsoides*, *Clerodendron Balfourii*, and the sombre greenish-yellow-flowered *Erica depressa*, all profusely bloomed, and in excellent condition, very few of them being less than 4 feet in diameter. Mr. W. Chapman, gardener to J. Spode, Esq., Rugeley, had a well-grown group, the most noticeable plant in which was a superbly-finished specimen of *Ixora Dixiana*, covered with great globular clusters of brilliant orange-red flowers. The same exhibitor had also a fine plant of the new hybrid *Ixora Williamsi*, a variety with bright orange-red flowers, in trusses fully 6 inches across; likewise a plant of the old *I. coccinea*, beautiful specimens of *Aphelexis macrantha rosea*, *Clerodendron Balfourii*, and *Erica Cavendishiana*. Foliage plants came from Mr. B. S. Williams, who had well-coloured examples of *Croton pictum* and *variegatum*, *Pandanus Veitchii*, *Gleichenia semivestita*, a superb specimen, but nearly hidden by other plants, and *Cycas revoluta*. Mr. Chapman's group included *Croton angustifolium variegatum*, *Latania borbonica*, and two or three other ornamental Palms. Mr. Carr, gardener to J. Hinds, Esq., of Weybridge, had a small but well-grown group, in which we noted *Alocasia Veitchii* (with glaucous, silvery veined foliage), *Maranta Makoyana*, and *Prichardia pacifica*. Mr. Clark, gardener to A. Shuter, Esq., 66, Belsize Park, staged half-a-dozen well-grown *Caladiums*. Mr. G. Legge, gardener to S. Ralli, Esq., had well-grown specimens of *Dracena Baptisti*, *Croton Youngii*, *C. Wisemanni* (a fine cone-shaped plant, 5 feet in height), and a good specimen of *Geonoma pumila*, a graceful stove Palm.

Ferns.—These were well represented and, as usual, much admired, their cool looking masses of green foliage serving to tone down and set off to advantage the bright colours with which they were associated. Mr. B. S. Williams had a fine specimen of the new *Alsophila australis* var. *Williamsii*, a drooping or weeping form, in which the contrast between the black trunk and deep green fronds was very effective. The same exhibitor had also a fine group, in which we noted *Adiantum Farleyense*, nearly a yard through; *Davallia Mooreana*, with fresh green fronds fully 4 feet in length; *Gleichenia Speluncæ*, and five specimens of the rare *G. Mendellii*, *Cibotium Scheidei*, and *Dicksonia antarctica*. Mr.

R. Richie, gardener to H. Prance, Esq., Hampstead, had a well-grown collection, in which were *Davallia Mooreana*, 7 or 8 feet across; a vigorous specimen of *Gleichenia microphylla*, and a fresh plant of the ever beautiful *Adiantum Farleyense*. A group of new Ferns, from Messrs. Jackson, contained one named *Phegopteris Dianæ*, a native of St. Helena, which was strikingly beautiful, its large flat fronds being finely divided, and of the freshest green tint imaginable. The same exhibitor had also a finely-cut form of the Lady Fern named *Athyrium felix-femina Jacksoniæ*. Mr. Williams showed *Gleichenia rupestris glaucescens*, *Dictyogramma japonica variegata*, *Adiantum gracilimum*, *Polystichum angulare* var. *congestum*, the curious proliferous *P. lepidocaulon*, and a small plant of *Platyserium Wallichii*. Messrs. Ivery, of Dorking, staged a small collection of hardy Ferns in a very fresh condition, many of them as delicately beautiful as the exotic species.

Azaleas.—These were, on the whole, well represented. Indeed some of the specimens were so profusely flowered that a leaf could scarcely be seen. In the amateur's class for six specimens, Mr. A. Patty, gardener to R. Thornton, Esq., of Sydenham Hill, was first with *Extranii*, *Criterion* (soft rosy-salmon), *Holfordiana*, *stella* (crimson-scarlet), and *Striata formosissima* (white, striped with rose). Mr. J. Child also staged excellent examples of *A. Barclayana* (white), *Telfordii* (semi-double crimson), *Arborea purpurea*, *Duchesse Adelaide de Nassau* (scarlet), *Iveryana* (white), and *semi-duplex maculata* (rose). Mr. G. Wheeler contributed some well-flowered plants, among which *Extranii* was a perfect mass of bright rosy flowers; and a plant of *Etirole de Flandres* attracted considerable attention, fully half its flowers being red, while those on the other half were white. In the nurserymen's class, Messrs. Ivery were first with small, but profusely bloomed, plants of *Elegantissima* (white), *Chelsonii* (bright scarlet, finely frilled), *Charles Enke* (a bright rosy-salmon, edged with white), and two or three others equally good. In the nurserymen's class for twelve plants, the same exhibitors furnished some pretty examples of skilful cultivation. Among these *Flag of Truce*, a double white variety, was well nigh perfect, both as regards growth and bloom. Messrs. Lane and Mr. Chapman showed effective groups.

Heaths.—These were well shown by Mr. Ward, Mr. Wheeler, Mr. Morse, and Messrs. Jackson, and in all cases the plants were fresh-looking and well-flowered. In the class of six plants, Mr. Ward had a large specimen of *Erica ventricosa magnifica*, studded with bright rosy flowers; *E. eximia superba*, a fine shield-shaped mass of rosy-green-tipped flowers; a good plant of the glaucous-leaved *E. elegans*; as also of *E. tricolor impressa*, a kind with large salmon-tinted white flowers. Mr. G. Wheeler had *E. ventricosa coccinea minor* (rose), *E. Cavendishii*, and the old white *E. candidissima*. Mr. Morse contributed a good plant of the bluish-tinted *E. mirabilis*, one of the prettiest of all Heaths; a good specimen of *E. insignis*, and the bright rosy-crimson *E. Westphalingii*. Messrs. Jackson, who were first for six Heaths in the nurserymen's class, had a perfect specimen of *E. ventricosa coccinea minor*, fully a yard in diameter, and profusely bloomed. Messrs. Jackson were also first for twelve Heaths, of which Mr. Ward had a dozen well-bloomed specimens, and was first in the amateurs' class.

Orchids.—Of these half a dozen good specimens came from Mr. B. S. Williams, the kinds being *Cattleya Mossiæ*, with seventeen flowers; *Cypripedium barbatum*, with forty flowers; *C. villosum*, with twenty flowers; *Lælia purpurata*, with seven good spikes, bearing five or six flowers each; *Vanda tricolor*, with three spikes; and a fresh and healthy plant of *Aërides odoratum majus*, with seven spikes; Messrs. Jackson also had a good and well-bloomed collection, in which were a superb variety of *Cattleya Mossiæ*, bearing some twenty flowers; *Odonoglossum citrosum*, with four good spikes; a well-grown *Vanda insignis*, with nine spikes; *Dendrobium macrophyllum* (macranthum) giganteum; and *Cypripedium villosum*, and *Saccolabium præmorsum*. Mr. J. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, staged examples of *Dendrobium Farmerii*, with five spikes; *Aërides Fieldingii*, with three branched spikes; *Cypripedium Stonei*, with two four-flowered spikes; *Oncidium ampliatus majus*, with seven branched spikes, the longest fully a yard high; *Lælia purpurata*, and *Vanda suavis*. Mr. J. Ward showed superb examples of *Odonoglossum Phalæopsis*, nearly 2 feet in diameter, and bearing about 10 fully expanded flowers. The most remarkable plant in this group, however, was a specimen of the new *O. vexillarium*, bearing eighteen great deep rosy flowers on three spikes. The foliage of this plant was tinged with purplish-brown, and one spike alone bore seven fine flowers. Mr. Morse, Epsom, Mr. Richie, and Mr. G. Wheeler, also furnished collections. Messrs. Veitch & Sons contributed some rare Orchids, the most remarkable among which were *Vanda Parishii*, with two strong spikes; *Cattleya Mendellii*, with a three-flowered spike—the contrast between the snow-white perianth segments and the rich carmine lips being very beautiful; *C. gigas*, with a three-flowered spike of mauve flowers, the rich crimson-purple lips having two whitish eye-like spots, which give additional brightness to the rich colouring. From the same firm also came *Pescatorea Dayana*, a species in the way of the better-known *P. cerina*, but with segments tipped with dark crimson, *Cattleya tricolor*, *Cypripedium selligerum*, *Lælia elegans alba*, and others, making altogether an effective group.

Hardy Herbaceous Plants.—Of these Mr. R. Parker contributed a well-arranged collection, in which were *Orchis foliosa*, bearing a dozen spikes of purple flowers, and rose and crimson-coloured varieties of *Pæonia officinalis*; *Hyacinthus amethystinus*, with some twenty or thirty slender spikes of porcelain-blue flowers; and a white-flowered and effective *Pyrethrum* named *Boule de Neige*. The same exhibitor had also a fine potful of the rich purple *Iris spectabilis*, bearing a dozen deep velvety flowers; a dense mass of *Scilla cernua rubra*, bearing numerous

spikes of rosy-lilac blossoms; *Spiræa japonica* and *S. palmata*, both excellent in their way; a snowy mass of *Iberis corifolia*, and a plant of the Irish Butterwort (*Pinguicula grandiflora*). Mr. G. Wheeler, who was second, had an interesting group of Wallflowers, Primulas, Irises, Saxifrages, Lupins, and *Iberis*.

Roses in Pots.—These were well represented by excellent groups furnished by Messrs. Paul & Son and Mr. Charles Turner, who were the only competitors. Messrs. Paul had well-flowered plants of Madame St. Joseph, a delicate salmon-tinted Tea variety; Marie Rady, crimson; Celine Forestier, sulphur-coloured Tea; Vicomte Vizier, deep velvety-crimson; Souvenir d'un Ami, soft rosy Tea; Madame Alice Durian, bright rosy-lilac; Victor Verdier, deep rose; and Camille Bernardin. Mr. Turner showed Madame T. Levet, silvery-rose; Paul Verdier, crimson; La France, rosy-blush; Souvenir d'un Ami, blush; Madame Victor Verdier, crimson; Anna Alexieff, soft rose; and Charles Lawson, bright rose. In the class of six Roses in pots, the position of the competitors was reversed, Mr. Turner being first and Messrs. Paul & Sons second, both contributing well-grown profusely-bloomed plants. In the class of twenty Roses in pots, Messrs. Paul & Sons were first with small, but profusely-flowered, specimens; and Mr. Turner was second.

Florists' Flowers.—What are called show Pelargoniums were well represented, Mr. James, gardener to W. F. Watson, Esq., of Isleworth, having well-grown shield-shaped plants, and the same exhibitor was also first in the open class for nine specimens. In the class for nine show Pelargoniums, in pots not larger than 8 inches across, Mr. J. Ward was first, and had splendid examples fully 4 feet in diameter, and profusely bloomed. The varieties were Warrior, scarlet and black; Royal Albert, salmon and black, white eye; Mary Hoyle, pale rose, maroon blotch; Maid of Honour, white and lilac, dark blotch; Desdemona, white, reddish-brown blotch; and Rob Roy, bright rosy-lilac, dark blotch. Mr. Bull sent a new semi-double Pelargonium, with purple flowers, named *P. cucullatum* fl. pl. Mr. Bull also exhibited a new Pelargonium, named Beauty of Oxtou, with rich maroon white-edged flowers. Mr. G. Brand staged six plants of his new white Pelargonium Duchess of Edinburgh, one of the best of all new kinds, invaluable as a decorative plant. Mr. J. George sent a group of new Ivy-leaved Pelargoniums, some of which have very fine flowers, rose, white, lilac, and scarlet being the principal colours. For basket-work or boxes these varieties will be found useful. C. B. Forster, Esq., sent three groups of new fancy Pelargoniums, several of which were certificated. Three new Azaleas came from Messrs. Ivery, among which were Sunrise, a dense-habited plant, bearing a profusion of white-edged salmon-striped flowers; Emma Ivery, deep rich rosy-crimson; and Butterfly, pale rose, margined with white, red blotch. Messrs. Jackman staged two splendid new Clematis—one, *C. alba magna*, has flowers measuring quite 8 inches in diameter, the segments being nearly 3 inches across, and as delicately fashioned as a Phalænopsis; the other, *C. Mrs. Hope*, bears flowers of a delicate bluish-lilac tint, 6 inches in diameter. Both are lovely additions to this beautiful group of decorative plants. Herbaceous Calceolarias were staged in admirable condition by Mr. James and Messrs. Dobson, both of whom had effective groups, in which the colours were very rich and bright. Mr. C. Turner sent a new seedling forcing Pink, named Derby Day, a large flower of a rosy tint, with dark marking.

Botanical Certificates were awarded to the following new and rare plants:—

Agave Besseriensis major (Croucher).—A robust form of this very variable species, with glaucous rigid leaves, each terminated by a formidable dark brown spine.

A. Veitchii (Croucher).—A dense growing plant, with deep green leaves, each about a foot in length.

A. Beaucarnea (Croucher).

A. marmorata (Croucher).—A robust growing plant, with recurved glaucous foliage of great substance.

A. polyantha (Croucher).—A long-leaved glaucous species of ornamental habit.

A. Pilgrimi (Croucher).—A dwarf deep green-leaved species of the *A. horrida* type, and a welcome addition to this dwarf-growing section.

A. pubescens (Croucher).

A. (Fourcroya) variegata (Croucher).—This plant has long slender foliage, and somewhat resembles a weak form of *A. americana* in habit and colour.

Dasylium longifolium glaucum (Croucher).—A graceful-habited plant of tufted habit, having long glaucous foliage. It is a welcome addition to a well-known group of decorative plants.

Athyrium f. f. Jacksoniæ (Jackson & Sons).—This is a very beautiful variety, with fronds about 2 feet in length, very delicately cut, and of the freshest green colour imaginable.

Phegopteris Dianæ (Jackson & Sons).—This is a strong-habited and very ornate Fern from St. Helena, having tripinnate fronds of leathery consistence and a delicate light green colour.

Dioscorea retusa (Veitch).—A climbing plant, with deep glossy green five-lobed leaves. It bears Hazel-like catkins of a Pea green colour, and is a very distinct and effective decorative plant.

Vanda Parishii (Veitch).—A rare and distinct Orchid, bearing seven-flowered erect spikes of waxy flowers. The sepals and petals are of a light green tint, blotched with brown, the trowel-shaped lips being of a bright carmine colour. The plant is dwarf in habit, the leaves somewhat resembling those of *Phalænopsis grandiflora*.

Cattleya tricolor (Veitch).—A slender-growing Orchid, bearing creamy-white flowers, the pure white convolute lips being blotched with lemon-yellow, and streaked with bright red. It is a very distinct and effective species.

Cypripedium selligerum (Veitch).—A new hybrid Lady's-slipper, the result of a cross between *C. barbatum* and *C. lævigatum*. The leathery leaves are of a glossy green, with dark markings, and the flowers are borne on a tall two or three-flowered purplish scape. In colour they most resemble those of *C. barbatum*, but the petals have a tendency to elongate. It is a very effective and free-blooming plant, of vigorous habit.

Nepenthes alba marginata (Veitch).—A very pretty little Pitcher Plant.

Abutilon Darwinii (Veitch).—A dwarf and free-blooming Malvad, with heart-shaped leaves and axillary orange-scarlet flowers.

Agave Salmiana fol. aureis variegatis (Veitch).—A strong-growing American Aloe, with stout leaves striped with creamy-yellow or white.

Adiantum Hendersoni (Veitch).—A strong-growing and very ornate Maiden-hair Fern, with gracefully-arched fronds 2 feet in length. The young fronds are of a bright purplish-brown tint, and the plant well deserves culture.

Platyterium alciorne Wallichii (Veitch).—A stout-growing Stag's-horn Fern of distinct habit.

Odontoglossum vexillarium album (Veitch).—A very pale form of one of the most beautiful Orchids in cultivation.

Acalypha marginata (Williams).—A very effective stove foliage plant, of easy culture.

Agave marginata (Williams).

Alsophila australis Williamsii (Williams).—A Tree Fern of graceful habit, the fresh deep green fronds drooping around the dark brown stem.

Geonoma gracilis (Williams).—A stove Palm, of easy culture and elegant habit.

Platyterium Wallichii (Williams).—A very ornamental Fern, belonging to the Stag's-horn group.

Dictyogramma japonica variegata (Williams).—A strong growing Fern, with leathery pinnate fronds, of a fresh green colour, and well worth culture as a distinct and effective variety.

Polystichum lepidocaulon (Williams).—A distinct stout-growing plant, with simple pinnate fronds, the rachis of each being prolonged into a proliferous caudal appendage.

Sonerila Hendersoni (E. G. Henderson).—A very beautiful stove, foliage, and flowering plant, with ovate deep green leaves, marbled with silvery-grey. The flowers are of a delicate rosy-lilac colour, and very freely produced.

Dendrobium Wardianum var. (Low & Co.).—A very thick bulbed short-jointed variety of a well-known Orchid, bearing large and richly-coloured flowers.

Blandfordia princeps (Bull).—A free-growing grassy-leaved plant, bearing erect spikes of rich orange-yellow drooping flowers, shaded with red at the base. Well worth culture as a greenhouse decorative plant.

Athyrium f. f. apicale (Bull).—A very beautiful form of the common Lady Fern.

Osmunda obtusiloba (Bull).—A strong-growing North American half-hardy sub-aquatic Fern, having elegantly lobed fronds of a light green colour.

Sadleria cyathoides (Bull).

Cibotium glaucum (Bull).

Nephrodium truncatum (Bull).—A free-growing decorative Fern, well suited for greenhouse culture, having a plume-like habit of growth.

Floral Certificates were awarded to the following:

Clematis alba-magna (Jackman).—A very attractive decorative variety, bearing great star-like satiny-white flowers 8 inches in diameter, the segments being nearly 3 inches across in the widest part.

Clematis Mrs. Hope (Jackman).—A bluish-lilac variety with full broad-sepal flowers about 6 inches in diameter.

Clematis J. P. Gassiot (Jackman).

Pelargonium Sappho (C. B. Foster).—A large round flower of a rosy-vermillion colour tinged with lilac and having a blackish blotch.

P. Eclipse (C. B. Foster).—A rosy-salmon suffused with scarlet, with a black blotch.

P. Flirt (C. B. Foster).—A large rosy-lilac flower of good form, the upper petals nearly all black with red margins.

P. Edith (C. B. Foster).—A soft rosy-salmon-tinted variety with dark blotch and distinct white eye.

P. Revenge (C. B. Foster).—A brilliant fiery scarlet, with a dark-feathered blotch, very bright and distinct in colour.

P. Beauty of Oxtou (Bull).—A free-blooming decorative variety of dwarf habit, the flowers being of a deep maroon tint blended with scarlet and margined with white. It is a fine companion to Queen Victoria, which, in habit and shape of flower, it resembles.

Fancy Pelargonium Miss Porter (C. Turner).—A very bright light-coloured flower, delicately tinted with rosy-lilac.

Pelargonium Countess of Dudley (C. Turner).—A free-blooming variety of dwarf habit.

Forcing Pink Derby Day (C. Turner).—A dwarf-habited free-blooming Pink, bearing large full fine coloured flowers, with dark velvety markings.

Spirits of Camphor as an Insecticide.—Allow me to inform "E. W. H." (see p. 436) that I never heard of camphor being used as a fertiliser; but, for some years past, I have found spirits of camphor and soft soap to be an excellent insecticide.—T. B.

Keeping Mice off Peas.—I have never tried soaking Peas in bitter aloes or Gentian to save them from mice as mentioned by your correspondent (see p. 416); but I find that slightly coating them with red lead before sowing answers the same purpose. Will your correspondent tell us what the strength of his steep is?—R. McK.

William the First Pea.—I have this day (May 26) picked my first dish of William the First Peas; they may be somewhat later than Ringleader, but very little; Ringleader we picked the day before, all being sown on the 9th of November. It never had any protection, except coal ash when first coming up.—R. GILBERT, *Burghley*.

—This bids fair to shortly supersede all the old early round kinds; it yields Peas fit for use quite as early as Dillestones, and it has, in addition, large handsome well-filled pods. Growers for market will find it worth their attention.—A. D.

Black Fly on Cherry Trees.—I never remember seeing the Cherry trees, particularly Morellos, so infested with the black fly as they are this season. They are easily killed with gas water diluted with one-third of pure water. Take a common garden saucer, and dip the ends of those affected, gently rubbing the shoot when in the solution.—R. GILBERT.

Northampton Hero Broccoli.—I notice that Mr. Tillery recommends various kinds of Broccoli in THE GARDEN. I was asked by Mr. Watts last season to try Northampton Hero. On the 15th of May I cut two of snowy whiteness, beautifully compact, not over large, but of the best quality.—R. GILBERT.

Morris's Measuring Instrument.—In external appearance this resembles a watch and it is much the same in size, the dial face representing the feet and inches instead of hours and minutes. Like the chartometer by the same maker, figured by us some time back (see p. 528, Vol. VI.), it has a small steel wheel projecting from the side which, when made to traverse the surface to be measured, turns round the hands, the larger of which indicates the inches and fractions of an inch, the smaller hand the feet, and the third hand the tens of feet. It is an ingenious little instrument, which for many purposes will, doubtless, prove useful.

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare.*

ROCK-GARDEN AT EASTER DUDDINGSTON LODGE.

OR the benefit of those amongst your readers who are lovers of Alpine plants I gave at p. 453, Vol. IV., of *THE GARDEN* a brief account of the rock-plant department at Easter Duddingston Lodge, the residence of Mr. Charles Jenner. Since that time considerable additions have been made to it. In my previous notice of this collection, I particularly alluded to the dwarf shrubby Ericaceous Alpine plants. I will now endeavour to furnish a few remarks on the herbaceous Alpines for which this garden has been long famous. About 1,200 of these interesting plants are cultivated at Easter Duddingston in pots, in a pit 94 feet long, 4 feet wide, and 2 feet 6 inches in height. The pots are all plunged in sand.

It would be needless here to give a complete list of their contents. Suffice it to say that the collection contains many novelties both in, and showing flower. At present, *Primula Parryi* is particularly noticeable, its beautiful rich blooms, of a dark purplish colour, being very attractive. *Lewisia rediviva* is growing here vigorously, and is covered with buds. How to get this botanical gem to flower seems to puzzle many. The plant in question, like all the other Alpines in pots, is plunged in sand up to the rim of the pot, and a bell-glass is kept constantly suspended a few inches above it. This prevents rain or artificial moisture from touching its crown, and the sand bath, which is occasionally moistened, is sufficient to keep the soil somewhat damp, an arrangement better suited for its growth than surface-watering. The *Lewisia* is perfectly hardy, and, if treated in this way, flowers annually. It is grown in a mixture of loam and peat, having a few pieces of sandstone placed over the surface of the pot. *Ranunculus parnassifolius*, a plant now rarely seen in cultivation, also flowers profusely here; and *Meconopsis aculeata*, a charming blue Poppy from the Himalayas, has a spike of flower buds about 1 foot high, the uppermost buds opening first; and, as several spikes are generally produced on the same plant, a long-flowering period is obtained. The yellow *Meconopsis Wallichiana*, from the same mountains, may also be seen in this collection; and besides these, numerous other interesting Alpines are here cultivated in pots, such as *Ramonda pyrenaica*, *Dianthus alpinus*, *D. Tymphrestus*, and *D. glacialis*, *Trifolium uniflorum*, and all the rarer species of *Primula*, *Soldanella*, *Gentiana*, *Androsace*, *Astragalus*, and *Oxytropis*. A pit, 58 feet long, 4 feet wide, and 2 feet high in front, is devoted to the culture of bulbous and tuberous-rooted plants. The surface, after being well drained, has been arranged into two hundred stone compartments, varying from 6 to 12 inches in diameter; and in these the roots are planted out in soil suitable for them. During early spring, these bulbous plants produce a pleasing display, owing to the number of plants then in bloom; but, at present, few are in flower. Among such as are in blossom, *Narcissus triandrus*, *Scilla amoena*, *Leucocoryne alliacea* and *uniflora*, several species of dwarf *Alliums*, *Fritillaria kamschatkica*, with its curious black flowers, and *Corydalis nobilis*, a truly magnificent species, are the most conspicuous. The Alpine plants, forming the chief open air collection, are cultivated in triangular stone compartments, arranged round a series of raised geometrical clumps, making altogether 1,400 divisions of various sizes, as

previously described in *THE GARDEN*. Many of the specimens are large and wide-spreading, and now present a magnificent appearance, both in and out of bloom. The following measurements of the circumference of a few of the leading species will give an idea of the way in which Alpines thrive when turned out of pots. *Salix reticulata*, 7 feet round; *Iris cristata*, 3 feet 9 inches; *Lithospermum fruticosum*, 3 feet 9 inches; *Epilobium obtusifolium*, 3 feet; *Arctostaphylos alpina*, 2 feet 6 inches; *Phlox setacea*, 5 feet; *Phlox setacea violacea*, 5 feet; *Cornus canadensis*, 4 feet 6 inches; *Teucrium pyrenaicum*, 3 feet 9 inches; *Aubrietia Campbells*, 4 feet 6 inches; *Rubus arcticus*, 2 feet; *Trifolium uniflorum*, 2 feet 3 inches; *Arenaria purpurea*, 2 feet 6 inches; *Rosa pyrenaica*, 5 feet; *Veronica Guthriana*, 4 feet 6 inches; besides these, the early *Saxifrages*, *Pentstemons*, *Lithospermum Gastoni*, *Ramonda pyrenaica*, *Iberidella rotundifolia*, *Dracocephalum grandiflorum*, *Hutchinsia alpina*, *Dianthus alpinus*, and *Gentiana verna* are all large and worthy of notice. The surface soil of all the angular stone compartments slopes slightly towards the back, an arrangement which enables the rain or water given artificially to soak immediately to the roots, instead of running off, which it is apt to do when the ground slopes towards the front. In making rocky gardens, this is a matter worthy of attention, inasmuch as the water soaking, as it does, into the stones behind, enables the roots to exist in dry seasons on the moisture imbibed by them for a much longer period than could possibly be the case under any other arrangement. On one portion of the ground, in connection with the geometrical rock-garden, a large corrie or gully has been formed, running east and west, and the internal, as well as external, irregular undulating slopes of this are, for the most part, formed into pockets for the accommodation of plants; and broad, shelving stone projections, the under-sides of which afford shelter to plants that require more shade than can be obtained in the ordinary outside compartments, where the sun has full access to them. These arrangements have been skilfully carried out under the direction of Mr. Charles Howie, of Largo, a gentleman, whose love for British Alpines, and knowledge of the localities in which they naturally grow, has enabled him to do ample justice to Mr. Jenner's collection. Besides the rock departments, a considerable extent of ground is devoted to hardy herbaceous plants. Of these, several hundred species are systematically arranged in borders. Like the Alpines, the plants are all numbered, and entered in a garden book. The Ericaceous section at Easter Duddingston is also very extensive; the plants, however, instead of being cultivated in stone pockets or compartments, are spread over the surface of the raised beds, which are surrounded, as has already been stated, with the angular stone boxes for the growth of the herbaceous Alpines. Hardy and half-hardy Ferns are also especial favourites at Easter Duddingston, the stronger kinds being grown on rock compartments having a northern aspect. A house, 21 feet long, 6 feet wide, and about 8 feet in height, is arranged into two divisions—the back and sides being fitted up with rock-work—and is almost wholly devoted to the culture of *Scolopendriums*, of which there is here a good collection, all in the most perfect health. The roof, which slopes to the north, represents a series of steps, the upright portions only being of glass; with the exception of 3 feet of brick wall at the bottom, all the rest is open, and water from a small perforated pipe keeps the whole moist. The rarer British Ferns are all well represented, one glazed pit, 6 feet long and 3 feet 6 inches wide, having a northern aspect, is entirely devoted to the *Cystopteris montana*, which are in excellent condition. The roots run vigorously over the peat soil in which they are planted, and many of their fronds measure from 8 to 12 inches in length. Advertised novelties in the way of Alpines are generally small when first offered for sale, and often so weak that great care is necessary to keep them alive; so, instead of giving a small price, say 2s. 6d., for a plant, it is better to give 7s. 6d. for one three times the size. In this way good flowering specimens may be got up at once, instead of having to wait a year or two nursing them into vigorous growth. Were this system more generally practised, the disappointments now experienced would not be so great, even though fewer specimens were bought. J. M'NAB.

NOTES OF THE WEEK.

— THE Madresfield Court Grape is now, and has been for the past fortnight, in good condition, in Covent Garden Market. It has the finest flavour of all the Grapes ripe at this early season. The specimens in the market have been grown by Mr. Wilmot, of Isleworth.

— A SUM of £500 has been included in the estimates as a salary for an assistant-director of Kew Gardens. Professor Dyer has been appointed to the office. He has for some time past acted as secretary to Dr. Hooker.

— M. RIVIÈRE reports that the plantations of Eucalyptus in Algeria have had an excellent effect from a sanitary point of view, certain spots noted for their unhealthiness having become comparatively free from disease.

— IN the Chiswick Gardens fruit trees are bearing abundant crops. The orchard-house trees, too, are laden with fruit, as are also those in the long Peach-house, or glass wall, as it is sometimes called. Trials are being made of Pansies, bedding Geraniums, Onions, and other flowers and vegetables.

— AT least one "distinguished" alpine flower now adorns the flower-shops and stands in Covent Garden. The beautiful pyramidal Saxifrage, which in early summer rears its little tree of flowers so frequently on the sunny side of the Alps, is now in perfection in small pots in Covent Garden. It is used for table and room decoration.

— Two striking panfuls of *Utricularia montana* were shown the other day at Croydon; their flowers were borne on long flexuose spikes, and were of a snow-white colour with a blotch of lemon-yellow on the broadly-expanded lip. In colour and size they reminded one of *Phalæopsis grandiflora*. They were grown by Mr. Hill, gardener to Sir William Marriott, of Down House, Blandford.

— WE have to hand Mr. Riley's excellent and exhaustive "Seventh Annual Report on the Noxious, Beneficial, and other Insects of the State of Missouri." Although local, being written for one American state, it is of interest to the world at large, from the vast mass of important information which it contains in reference to the Phylloxera, the Locust, and many other insects, and from its excellent illustrations.

— THE annual meeting of the United Order of Free Gardeners took place at Newcastle the other day. The President said that since the last meeting about 2,000 had been added to the roll of membership, which now numbered upwards of 140,000; that the contributions had been £41,303; and that the amount expended for sickness and funerals £36,389.

— THE remarkably fine Tomatoes shown by Mr. Miles, of Wycombe Abbey Gardens, at South Kensington, the other day, shows that, wherever there are hothouses, it is an easy task to have these in perfection a good many weeks earlier than they appear in our markets. The Tomato is every day becoming more popular; and the many who enjoy it will be grateful to cultivators who thus lengthen the season when it may be had in perfection.

— THE "Florist and Pomologist," for June, contains coloured plates of the new *Echeveria Peacockii* (one of the most distinct and effective of the whole genus, a native of New Mexico, and synonymous with *E. Desmetiana*) and the Condor Peach (one of the latest and best of Mr. Rivers's seedlings). The latter bears fruit of medium size, with a distinct suture and nipple-like point, the downy skin being yellow washed and speckled with rosy-red. The flesh is whitish, blotched with red near the stone, juicy, piquant, and rich.

— THE first dinner of the new Horticultural Club took place on Wednesday evening, when a considerable number of gentlemen interested in horticulture met together at the club rooms, 3, Adelphi Terrace. The avowed object of the founders of this club is to promote a social organisation for horticulturists which may be free from any kind of cliquism. So far, this aim seems to be in a fair way of being realised. The secretary is the Rev. W. H. Dombrain, Westwell Vicarage, Ashford, Kent.

— WE had frost here (writes a correspondent, who resides 6 miles east of Nottingham) on Sunday night last, but, luckily, we lie high, and the air was dry. I hear that, in the Valley of the Trent, Potatoes have suffered to some little extent. To day (June the 1st) the sun has been burning hot, with a cold east wind blowing. Looking over Pears the other day, I found that the promising appearance which they had when in bloom will not be maintained as regards fruit. Some kinds (Winter Nelis, for instance), which were literally white with bloom, have scarcely set a fruit.

THE FRUIT GARDEN.

WALL FRUIT CROPS AND SPUR PRUNING.

ALMOST every kind of fruit has set so abundantly that thinning must be effected on an extensive scale, or both trees and crops will suffer. I find that Apricots are set equally as well on unprotected trees as upon those that have had coverings provided for them. I refer here to the temporary protection afforded by blinds and rollers, nets, &c., which are usually provided for the choicest wall fruits through the critical season of flowering; but I place most reliance on the wall itself, or rather the latent heat which is stored up in it during the day, and which protects the blossoms from injury during the night. For this reason I train all our wall trees as closely as possible to the wall; in fact, when nailed after the winter pruning, I like all the young wood to lie on the wall itself. It appears to me quite useless to build expensive walls and train the choicest trees upon them, and then allow their bearing-wood to extend so far from the masonry that they are in little better position than standards or espaliers. All spurs that project more than 2 inches from the wall I cut clean off, and train in a succession of young wood all over the tree, and I do not find any more difficulty in furnishing Apricots, Plums, and Pears, than I do in the case of Peaches and Morello Cherries. The fruit is both finer and more numerous on young wood than on old hard spurs, which, if allowed to grow on the extension system, soon get so bare at the base that it is impossible to prune them back without making unsightly gaps in the tree. When trees have been spur-pruned for several years, this is the best season for commencing to gradually renovate them by taking off the longest spurs and training in young growths to fill the vacancies. I never saw any harm occur through pruning when the trees are in full leaf. Pear trees are greatly benefited by this treatment; for, if spur-pruned year after year, they only produce breast-wood on two-thirds of the tree, and fruit at the extreme ends; and, although they do not usually fruit on the one-year-old wood, yet, the second and third seasons are nearly sure to give a crop of fruit on all young growths. There are some few kinds of each sort of fruit that appear as if they would bear crops under any circumstances, either pruned or unpruned, but I do not know a single variety that does not produce the finest fruit on the young wood. With fan-trained trees for stone fruits, and horizontally-trained ones for Pears; a good supply of young bearing wood evenly distributed over the tree; the roots mulched so that they never suffer from drought; all aphides destroyed on their first appearance; and a light and portable protection during the critical season, if a crop of fruit is not ensured, you may be certain that your neighbours, with heavy copings and permanent coverings, will not have a better one. After trying rollers, coping-boards, tiffany, and other contrivances, I must confess that our best protectors are old herring-nets, supported at least 1 foot clear of the trees; and, in case of severe frost, supplemented by light evergreen branches. All kinds of coping either blanch the young growth, or do more harm to the trees than is repaid by the crop.

J. GROOM.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Apple Blossom Maggot.—This is very troublesome here this season. It not only eats the fruit, but it punctures the leaves. For the last fortnight, during dull days, we have been well washing the trees with soap and water, applied by means of a powerful garden engine, and with apparently good results.—R. GILBERT, *Burghley*.

Grafted Vines.—I have had the Muscat Hamburgh grafted upon the Black Hamburgh, as I was recommended to do in order to give it increased vigour. Instead, however, of this being the result, it remained a weakly Vine, showing small bunches of indifferent Grapes, until I tried it again on its own roots, when it produced large and well-coloured bunches, although growing in a light sandy soil.—J. MILLER, *Clumber*.

Strawberries in Pots.—Referring to recent notes on the advantages of using pans and sods in Strawberry forcing, Mr. Gilbert, of Burghley, writes that "both sods and saucers are useless. I grow here 2,500 plants in pots. We have no Strawberry-house, but grow them in Vineries, Melon-houses, and Pine-stoves. Immediately they are coloured, we put them into cold houses to flavour, and just now we have about 200 flavouring in the early pot Vinery. We gather a daily supply of excellent fruit. If sods were used, shifting them would not be practicable, and as to emptying the saucers in dull weather, it would take up more time than can be spared."

Pruning Old Vines.—In some of the Vineries here the Vines were for years pruned upon the spur system—a practice which had the effect of rendering them very unsightly. In order to remedy this, and bring the spurs, so to speak, home again, I have used the knife freely amongst those that were stag-horn-shaped for several seasons. This is the third year in which they have been close-pruned, and it is astonishing to observe the growth they are at present making. They are showing an immense number of bunches, and, strange to say, even where I have pruned them into the old wood, dormant eyes have pushed out, and are bearing clusters of Grapes, with large healthy foliage, free from speck or spider, which, from the vigorous habit of the Vines, are heavily bespangled every morning with dewdrops, which dry off as air is given, but which I know to be a true sign of health.—J. MILLER, *Clumber*.

THE FLOWER GARDEN.

THE ANNUAL LARKSPURS.

Delphinium Ajacis or Ajax Larkspur.—This grows wild in the south of France, and extends along the Atlantic coast of that country as far as Nantes. It is also found in Portugal, Algeria, Italy, Turkey, southern Prussia, the Taurus, and its distribution extends even as far as the Baikal Lake, Siberia. *D. orientale*, as is indicated by its name, comes from the east and is sometimes confounded with the kind called *D. Ajacis*. In the latter the flowers are arranged in long loose spikes forming an erect and spreading panicle. The stem, which rises to a considerable height, is vigorous and pubescent and has open branches. *D. orientale*, on the other hand, has flowers in long spikes upright and closely packed, a glabrous stem branching but little, and upright shoots. In olden times the different varieties of *D. Ajacis* were cultivated in every garden. Among them were single blue, purple, rose, and white, and double kinds embracing all these colours, as well as prettily-variegated sorts, and then there was the kind called *Consolida regalis anglicana*, of which there were twenty varieties of different colours. We have now among garden Larkspurs many colours, but those who have turned their attention to this class of plants, have not specially applied themselves to developing the size of the flowers, to producing double varieties, or to altering the shape of the plant. We possess, at present, however, many large and dwarf varieties bearing single, double, and semi-double flowers, the double kinds being almost the only ones cultivated. All the varieties of the Ajax Larkspur have been collected into three great groups:—1. *Delphinium Ajacis majus* (the large Larkspur).—The stem of this is single, and varies from 3 feet to 4 feet 6 inches in height; the flowers are double, and form a long, single, and compact spike, generally rounded off at the extremity. This kind has produced the following varieties—white, flesh-coloured, rose, mauve or puce-coloured, pale violet, violet, ash-coloured, claret, and brown. 2. *Delphinium Ajacis minus* (small or dwarf Larkspur).—The stem of this is from 20 to 24 inches in height, and even shorter when sown thickly, or in dry or poor soils. The flowers are very double, and are produced in a single well-furnished spike, which is usually cylindrical, rounded off or blunt at the extremity, and rarely tapering. The petals are generally acute at their upper extremity. The principal varieties are

the following—white, mother-of-pearl, flesh colour, rose, mauve, pale mauve, peach-blossom, light violet, violet, blue-violet, pale blue, ash-grey, brown, light brown, white striped with rose, white striped with grey, rose and white, and flax-coloured and white. 3. *Delphinium Ajacis hyacinthiflorum* (dwarf Hyacinth-flowered Larkspur).—The varieties of which this group consists have been for the most part produced in Belgium and Germany. They do not differ at all from other kinds in the form of their flowers, but

only in the disposition of the inflorescence, the spike on which the flowers are set being more tapering, and the flowers themselves farther apart, than those in the two previously mentioned groups. As regards culture, these Larkspurs should be sown where they are to remain, any time after February when the weather will permit, but usually from March to April. They may also be sown in September and October, and even later when the ground is not frozen. The produce of these winter sowings is, however, always liable to be devoured by slugs and grubs. The sowing may be made either broadcast or in rows from 4 to 8 inches apart, and the plants should stand 4 or 5 inches asunder. In gathering the seed care should be taken only to save it from flowers that are perfectly double; single-flowered plants should, therefore, be carefully weeded out if good seed is to be obtained. Larkspurs are at their best between the beginning of June and July, and they will bloom almost anywhere, especially in dry localities, and do not require much attention. They look well either of one colour or of all the colours mixed, and by using varieties possessing different colours separately striking contrasts may be produced.

***D. orientale* (syn. *D. ornatum*).**—This has either single or semi-double flowers, that are violet, white, or rose in colour. It has also produced varieties possessing the same colours as the preceding, and which are generally used for the embellishment of borders, in which they are sown in the autumn or spring.

***D. Consolida* or *Branched Larkspur*.**—This pretty little plant is charac-

terised by branching stems and by flowers of a beautiful violet-blue hung on slender elongated peduncles. In a wild state, it is always found associated with Venus's Looking-glass, Fennel, and Corn-flowers. It embraces several varieties, both single and double, all of which may be reproduced from seed. The principal sorts are white, flesh colour, red, lilac, violet, flaxen, and variegated. Three varieties of it are especially worthy of being cultivated, viz., candelabrum, a kind that produces beautiful pyramidal spikes of flowers, ordinarily

Two varieties of tall double-flowered Ajax Larkspur.

of a blue colour; tricolor elegans, the form and foliage of which are like those of its type, while the flowers are rose-coloured streaked with blue or purple, and often double; and a variety remarkable for its deep rose-coloured flowers streaked with blue and red, sent out by M. Vilmorin, of Paris. As regards culture, this Larkspur and its varieties should be sown from February to April, either in the open border or reserve garden, and from September to November, leaving between the plants at thinning time a space of 8 inches; if in the reserve garden, they should be transferred to the beds in March when about 12 or 16 inches high, lifting them carefully with balls, in order that they may not suffer from transplantation. This class of Larkspur is specially adapted for the decoration of large gardens either in masses of one or various colours, or it may be planted in borders or amongst clumps of young thinly-planted trees. One great advantage belonging to this variety is that it flowers for a long time and earlier than *D. Ajacis*—that is to say, throughout the summer, and, according to the period of sowing, from the end of June or July to September, and even to October if care be taken to cut off the flower-stems that have shed their blossoms. It succeeds, moreover, in the driest calcareous soils, and even upon declivities and hills. By frequent pinchings dwarf plants of it may be obtained which are very valuable under certain circumstances.

D. cardiopetalum.—This plant grows wild in France, especially in the Pyrenees, and is remarkable for its very branching habit—the branches spreading at first, but subsequently becoming upright, thus giving the plant a bushy pyramidal appearance. The flower-stems are shorter than is the case with the preceding kinds, but more numerous. The flowers are of a beautiful blue inside, and paler and reddish outside, the interior divisions or petals being almost round. This kind is remarkable for the length of time during which it flowers, and for the abundance of its blossoms, the blue colour of which blends agreeably with the brilliant green of the foliage, the latter being thicker than that of other kinds. It succeeds in all kinds of soils, but best of all in those in which the calcareous element predominates. The above is a digest of an article, by M. André de Vos, that appeared in the first number for this year of the "Bulletin Horticole," a useful and well known Belgian publication. For the engravings, we are indebted to the courtesy of Professor Morren, of Liège.

Double-flowered dwarf
Ajax Larkspur.

GENTIANAS.

By general consent these are considered supreme among Alpine flowers for their beautiful hues. Among the Rock Speedwells, and Gromwells, and Harebells, and many other families we have numerous lovely blue and blue-purple flowers, but it is among the Gentians that we find blue flowers that startle us with the depth and brilliancy of their colour, and that sparkle in the early summer Grass as glow-worms do in the dark wood. The Gentians are mostly mountain flowers, or of those open heaths, upland pastures, and wide-spreading bogs, which in northern lands so often enjoy the fresh mountain air and its coolness. Occasionally they haunt the fringes of the stream, as in the case of the Bavarian Gentian, which is so exquisitely beautiful, beside many thousand Alpine meadow-rills in the

Alps of Europe, and the nobler, if somewhat less vivid-coloured Gentians, which adorn the rocks and banks by the great North American rivers and streams. Usually they are dwarf in stature, and compact in growth, but one very common species on the Alps, *Gentiana lutea*, may be classed with the most vigorous perennials. It, however, has not the charm of colour, but the lovely American fringed Gentians, while resembling our brightest European kinds in this respect, surpass them in size of blossoms, and spread forth into sturdy spreading bushes laden with fringed vase-shaped flowers. In a wild state, Gentians do not by any means require peculiar conditions as to position or altitude. The same kinds frequently abound on high snow-clad ranges, hoary in much of their Gentian-haunted surface until far into the early summer, and hills not more frequently covered with snow than the uplands of Britain; generally, however, they love meadows and moisture rather than the rocks or sands, and they crowd most of all into those wide Alpine pastures where they have to struggle for standing room with sturdy little Primroses and silvery Cudweeds and large Violets, that sometimes form an iridescent turf, standing clear above their tiny leaves. In our gardens it is quite possible to enjoy the beauty of the Gentians without much trouble, though these plants are as yet but little grown. They may, from the point of view of culture in our gardens be classed in two sections—the first of strong easily-grown kinds, suitable for borders, and the second of the dwarfer kinds which should be grown on the rock-gardens, or in borders or beds devoted to choice dwarf plants. The *Asclepias* Gentian, some of the American perennial kinds, and those with herbaceous shoots, generally grow freely in good moist soil in borders. So does the well-known *Gentianella* (*Gentiana acaulis*), which, however, being dwarf in habit, and large and splendid in bloom, is used as an edging plant. It is well to form carpets of this in parts of the rock-garden, planting in deep moist loam. The other type of Gentian, represented most familiarly by *Gentiana verna*, is by no means so difficult of cultivation as is commonly supposed. Want of moisture in the soil, want of free exposure to sun and air, and weak and imperfectly rooted plants, are the main causes of failure. In the cool, natural pastures and uplands, where the plant thrives in a wild state, it is rarely subjected to such drought as in a parched, cracked, and baked border. Deep, moist, sandy loam, will suit it perfectly; if the surface be strewn with bits of broken stone it is prevented from cracking and parching as it often does when bare. Well-rooted plants should be secured to begin with. It is important that the plant be not overshadowed or overrun by tall or straggling border flowers. This is easily guarded against by associating with it plants somewhat resembling it in stature. These various conditions observed, the Vernal Gentian will soon spread into strong tufts and take care of itself from year to year, forming carpets on the rock-garden and small beds or edgings on the level ground. The conditions it requires frequently occur in our gardens, particularly in elevated or sea shore districts, and in these it may be grown as edgings to groups of dwarf shrubs, &c. It is quite easily grown in pots or pans of sandy loam plunged to the rim in the open air in a fully exposed spot in summer, and freely watered through the growing season.

FLOWER GARDEN VASES.

SOME people seem to have no conception of ornamenting a balustrade, a terrace, or a stair, otherwise than by vases. Not long ago, in a moderately-sized semi-Italian flower garden, laid out in front of the windows of a substantial but unpretentious mansion, I counted nearly seventy terra cotta vases, all within as many yards of the drawing-room door. Every pier, on terrace and stair, was surmounted by a vase. The place was literally crowded with them, to an extent that one would not expect to see anywhere but in the manufacturer's show-yard, and the overlaid aspect of the scene was monotonous and wearisome in the extreme. A single vase, or even a group of vases, in a well-chosen situation has a pleasing and highly ornamental effect; but when the eye meets them wherever it turns, without discovering the least excuse for their presence,

the impression is disagreeable. The terra cotta vases, now generally used, are well made and chaste in design. They are also very durable, and do not turn green like vases of stone or other material; but to most people the yellowish pipeclay colour is objectionable, as it does not associate well with substantial stone masonry of any kind, while against foliage or a Grass lawn the contrast is still worse. A very popular form of flower vase is the tazza, but it is one of the worst for plants, the basin being too shallow to accommodate the roots of suitable subjects—even bedding plants are starved in them unless watered very frequently, which is not desirable; and I suppose the difficulty cannot be overcome without destroying the proportions of the design. Those, therefore, who desire to fill their vases with noble-looking fine-foliage plants, will do well to consider this before purchasing. The basket-formed vases are amongst the best for plants, and suit low piers and stairs; but they are not so handsome as the tazza, and have too much of the wash-basin form. The common, deep, cup-shaped vase, sometimes ornamented with panels and otherwise, is very handsome, adapted to most situations, and is one of the best for plants. There are some vases made with lids, which must be sparingly used, for they remind one irresistibly of soup tureens. Between these there are many other graceful forms suitable for all purposes. It is not desirable that the vases in and about the flower-beds should be furnished with the same kind of plants as the beds—I mean ordinary bedding plants; or, if they have to be used, they should be mixed and arranged in such a way as to afford a contrast. Some of the succulent class are well adapted for vases, and none surpass the *Echeveria metallica*, but the plants must be large—two or three-year-old plants, with good leaves; and single plants look best in moderate-sized circular vases. If the flower-spikes are encouraged to grow, the effect is much better, and, indeed, unique and striking. The *Sempervivum arboreum* is a tall symmetrical plant for a vase, but too stiff for some situations. Large plants of *S. canariense* are better for the purpose, and very interesting, and so is *S. giganteum*. The American Aloe, the green and variegated kinds, are very suitable, and general favourites with most people. *Yucca aloifolia variegata* is another excellent species when well furnished to the bottom. The hardier *Dracænas* are all first-rate vase plants, being wiry and enduring, as well

as ornamental. *Phormium tenax* and *tenax variegatum* are also amongst the best, especially the latter, its spreading fan-shaped form filling up the position well. In all cases the top of the plant should be in ample proportion to the size of the vase. A shabby plant in a fine vase looks ridiculous. Any of the Palms which are hardy enough for outdoor summer

work look well in a vase. *Latania borbonica* is one of the most useful and hardy. Most of the free-growing sub-tropical plants now in use may also be employed; but, as vase plants are frequently exposed to the wind, tender-foliaged subjects are disappointing. The Japanese variegated Maize, for instance, is a splendid vase plant, but the leaves get torn to ribbons with the wind; for fountain work in sheltered places it is matchless. Of formal-looking plants, I have used specimen Azaleas, putting them into large vases during summer, instead of on the border outdoors, as usual. If healthy and green, they look really well. The spire-like Juniper, also, is very effective in vases that are not too wide. *Centaurea gymnocarpa*—good large plants from sowings of the previous summer—is also effective, and as easy to get up as any. With some people the *Humea elegans* is a favourite; but, though it does well in a bed, it is a spare subject in a vase, and the foliage is seldom good, which gives it a starved appearance. Of flowering plants, the Fuchsia is one of the best; and spreading bushy plants, that have been cut down once or twice, and that will throw up a mass of shoots like *F. Riccartoni*, will be found by far the most useful and least troublesome to grow. None of the above-named species want much, if any, decorating by planting small plants around their stems or on the surface of the vase; they look better alone. A surfacing of *Lycopod* is, however, not objectionable about *Dracænas*, &c., if they are somewhat long-limbed. I have surfaced the soil of the shallower vases with patches of ground Moss (pegged on to keep the birds from disturbing it) to prevent evaporation. Ivy of the *maculata*

type, and also the common kind, may also be employed with good effect as a drooping plant, but the plants should be lengthy and supple when planted, as they do not grow much in vases. Periwinkle, also, is useful for carpeting the surface of the vase, and has a refreshing appearance; indeed, no creeping or trailing plant comes amiss that will grow, and they should be planted profusely. Vases are often employed with

Double Ranunculus-flowered
Larkspur.

Double dwarf Hyacinth-flowered Larkspur
(see p. 459).

good effect in secluded and appropriate corners of the lawn and shrubberies. In such situations these decorations should be rather different; a little colour is necessary for contrast, and the usual bedding-plants will effect this. For the centre of a vase a good group of tall one-year-old scarlet or pink Geraniums is well adapted, and round the margin the vase may be trimmed profusely with Calceolarias, Lobelias, Heliotropes, Mignonette, &c. The great point is to plant thickly at the first. Fill up the middle with the central plants, forming a good bush, and afterwards plant the sides with the smaller subjects. Deep vases should always be well drained, and, in planting, one or two inches should be left for watering, as, when they are filled too full, the soil gets washed over upon the piers and steps. An open, rich, loose soil is the best, for in vases the earth is apt to cake in dry weather, and it should not be rammed hard about the roots when planting is performed. I always use a rough compost of leaf mould and turfy loam. Before frost sets in all stone or earthenware vases should be emptied, as the expansion of the wet soil by freezing is apt to crack them.—“Field.”

MULCHING IN THE FLOWER GARDEN.

DURING hot dry weather vegetation frequently suffers more from heat and drought on strong land—from its tendency to crack into deep fissures, and thus part rapidly with its moisture—than on light sandy soil, where the surface remains intact. There is, too, a vast difference in the power of various soils, often even in the same locality, to absorb heat during bright sunshine, and it is on those soils which, either from their colour or composition may be termed hot soils, that the value of a thin covering of some non-absorbent retentive substance will be most appreciated. For several years past I have mulched nearly all the beds in our flower garden, and with the most satisfactory results. In the case of all plants which are benefited by a little extra nourishment, we mulch with short manure; but in the case of others, that usually make growth enough without any such support, we simply cover the beds thinly with short Grass, from which the plants derive much benefit, and the saving of labour in watering is very considerable. Indeed, I do not think that any amount of watering would produce the same result, because it tends to encourage surface rooting, and, every now and then, something occurs that for a short period, at least, prevents the accustomed supply being given, and, in a hot soil like ours, the young surface roots soon perish; where, however, the beds are mulched there is no occasion to feel uneasy about the water supply. In most cases it is best to put on the mulching as soon after planting is finished as is convenient. Verbenas, Violets, Ageratums, Calceolarias, Heliotropes, Iresines, Coleus, Tricolor Geraniums, &c., we mulch with manure decayed sufficiently to break up easily with a fork. I have generally used horse manure, but last season I obtained it from a bullock-yard, the manure from which is of a cooler character than that from stables, and better suited for a hot soil. The expense of the manure compared with the well-being of the plants and the saving of labour in watering, is a mere trifle. We turn out annually from 40,000 to 50,000 plants, exclusive of such as are hardy, and about five one-horse loads of manure suffice to mulch all that require such assistance. It should be placed evenly all over the surface of the beds with the hand, and where the appearance of the manure is objectionable, about an inch of fine soil should be placed over it, and all plants that require pegging down should receive that attention in good time. Pelargoniums of the scarlet section will stand a good deal of drought in a deep soil; but in hot summers a thin covering of short Grass or Moss is a great help to them, and, if put on in time, will prevent their losing their lower leaves. This class of plants usually makes growth enough, and, therefore, all they require is some thin covering to check evaporation. Petunias, when once established, even on the hottest and driest soils, never seem to require either watering or mulching; a dry hot season, in fact, suits them best, and very showy inexpensive beds they make when trained low on sticks bent over the beds.

Ramsey Abbey.

FRAGRANT ROSES.

THE Rev. J. B. M. Camm makes a sensible plea for these in the “Journal of Horticulture.” “I am afraid,” he says, “that fragrance is the last qualification that Rose-fanciers consider, and if raisers produce a Rose of first-rate form, good, distinct, and pure colour, strong in growth, and erect in habit, they consider that they have deserved well of their country, and that if the said Rose is quite destitute of fragrance the matter is of no importance. To a certain extent they judge rightly; for judges at exhibitions rarely, if ever, take the fragrance of the stand into account. I fancy I see the countenance of any of our leading judges (I do not like to mention names), if asked in the case of a disputed and difficult point of judging, to give the preference to the stand containing the most fragrant Roses! Yet, other qualities being equal, it would not be a bad way of deciding a vexed question. I remember the Royal Horticultural Society once gave prizes to Roses to be judged by their perfume, and I have still a catalogue in my possession where, on the outer sheet, the proprietor proudly informs the public that at this show he gained the first prize for “six Roses for smell;” but, alas! among other changes—notably that of refusing to pay the prize money—this is included, and the classes for perfume are withdrawn; so that there is now no encouragement to growers to cultivate Roses celebrated for their fragrance. I remember once, at Hereford, the Marquis of Bute gave a £5 prize for twelve best York-and-Lancaster Roses, but the competition was so small that the committee persuaded him to transfer his prize to table decorations. So fragrant Roses are left out in the cold, and we live in hopes that some of the larger societies or wealthy amateurs will offer a prize for this class at one of the great exhibitions. Now, as to fragrant Roses. Here, again, by far the best are the Tea Rose, and if I am asked to name the most fragrant Rose, I should say Devoniensis, and next place my own particular pets—Catherine Mermet and Madame Bravy—or Alba Rosea or Madame Sertot, as she is variously called. Souvenir d’Elise, the most lovely of all Teas, has a most distinct and peculiar fragrance like that of fresh tea, and though not so pleasant as the first-named, yet is equally sweet-scented. Maréchal Niel and Triomphe de Rennes possess a large amount of perfume, while Madame Willermoz reminds one of the most delicious fruit. This Rose, though rarely shown in perfection, is for fragrance almost unrivalled. Cloth of Gold is also very sweet-scented, and Rubens and Souvenir d’un Ami delight you with their perfume as well as charm you with their form. In fact, all the above-named Teas are good in every sense, and rarely, if ever, fail to bloom early and late. Of Hybrid Perpetuals it is difficult to give a list, as the majority of this latter class possess most exquisite perfume; but I can name a few which are remarkably good. Général Jacqueminot, among the dark Roses, is pre-eminent for perfume, and La France among the light. Abel Grand, too, is a most fragrant Rose; and that charming little button-hole Rose (which does remarkably well here), Boule de Neige, has a most sweet and distinct bouquet. Beauty of Waltham, among the light crimsons, is very fragrant, and Comtesse de Chabillant among the light pinks. Madame Furtado, that poor weak grower, whom I almost despair of ever seeing in her beauty, is most celebrated for her perfume; and Charles Lefebvre, the grandest of dark Roses, is also very sweet. The foregoing is an imperfect list, but if I were to name all the fragrant Roses I should want far too large a portion of your space; I have, therefore, only mentioned a few which in my opinion are most fragrant, and I hope other rosarians will supplement my list, and thus make an opening for another election of Roses, viz., those celebrated for their perfume.”

EFFECTIVE SPRING GARDENING.

I do not think I have ever seen anything more beautiful than the effect produced by my spring beds this year, and yet they are, without a single exception, composed of flowers which are most readily propagated, and within the reach of everybody. In the lower garden the lawn is an irregular square, with the corners rounded off; at each corner is a bed, about 17 feet long, and 3 feet 9 inches broad, placed about 3 feet from the margin, and following the curve of the lawn. These beds are divided into diamonds and half-diamonds, by a band of *Arabis lucida variegata* in the case of one opposite pair, and of *Golden Feather Pyrethrum* in the case of the other. Each bed contained three whole diamonds, with their corresponding halves, and a half-diamond at either end. In the case of one, the centre diamond is filled with Ware’s Cloth of Gold Pansy, and has on either side of it a diamond of Pansy Black Prince. The half-panels at either end contain Pansey Clevedon White, and these are flanked by corresponding half-panels of pink Daisy, the two remaining half-panels being filled with red Daisy. Nothing can be richer than this bed, which is solid with, I might say, thousands of blooms. The gold in

the middle, flanked on either side with crimson, and abutting again on the rich dark purple of Pansy Black Prince, is most striking; while the pink Daisies and white Pansies at either extremity, and, not least, the clear soft band of Arabis intersecting all, give a quietness to the whole which is very charming. The Daisies have been in flower for three months, and the Pansies for six weeks, and they are still one solid mass of bloom. The other beds are somewhat similar, but varied in their details; Myosotis, Pansy Magpie, Clevedon Blue, and others, being used to set off the pink, white, and red Daisies. I plant very thickly in October, manure heavily, and water occasionally with liquid manure.

In the upper garden I have a border, about 50 feet long, and 7 feet deep, planted in panels, V and A-shaped alternately, with similar materials, and intersected with the same Arabis, the effect of which is equally good. The masterpiece of all (while it lasted) was, however, a raised round bed, about 24 feet in diameter, situated in a conspicuous position. This was filled with 300 crimson Tulips (*Rex rubrorum*), and carpeted all over densely with *Cerastium tomentosum*. This was simply perfect, until the rain spoilt the Tulips; the *Cerastium*, with its soft grey foliage, contrasted most effectively with the brilliant bloom of the Tulips. I am now breaking up those beds to make room for their summer occupants, but I do so with reluctance, as they are still beautiful and bright, and will, I know, never be equalled by any compilation of Geraniums and Lobelias, which have needed so much attention all the long winter.

H. MILLINGTON.

Flowers on Railway Embankments.—Mr. Fish asks (see p. 450) whether the Primroses sprung up, on the bank to which he refers, naturally, or were intentionally sown there. I have no doubt that, in forming the bank, either seeds or roots were carried there along with the earth or turf. I can refer to a place on the North Kent line, near Erith, where a vast quantity of Valerian gives the bank a beautiful appearance in its season. As trespassers are pretty well kept off railway banks, a self-sowing plant is almost sure to spread, and such spaces may be easily rendered beautiful with little trouble or expense. The other day, in Staffordshire, I saw a bank blue with wild Hyacinths, and a few red Poppies before their natural season. Some thirty years ago, I tried sowing some Poppies on a bank of the South-western; but none appeared. I may

ask whether, as collectors are extirpating the varieties of wild Orchids, some could not be planted on railway embankments?—J. S.

Tuberous-rooted Begonias.—These plants are so fresh when in a young state, and bloom so freely, and, moreover, are so easy to cultivate, that they deserve a place wherever beautiful half-hardy flowers are grown. They are great favourites of mine, and the following kinds are all good and distinct:—Glitter is a vivid orange-scarlet variety, of good habit, and a profuse bloomer; the flowers are rather small, but this is amply compensated for by its brilliant colouring. Lothair, a soft rosy variety, with just a tinge of lilac, is

very beautiful. Masterpiece is one of the largest and best of the scarlet-flowered kinds, the blooms being of good substance. Lucinda is a very effective variety, bearing delicately-formed rosy-lilac flowers. Anacreon bears pointed blooms, of a remarkably rich tint. Apart altogether from their value as greenhouse decorative plants, however, they are very useful for dinner-table decoration, as both leaves and flowers show well under artificial light, and, for this purpose, plants about a foot high, grown in 48-sized pots, are best.—J. H. C.

New Hybrid Hellebores.—The following have been obtained by crossing *H. abchasicus* with *H. guttatus*, and others. Their superiority over older varieties consists in improved form, more floriferous habit, larger and finer flowers, of more distinct colour. Dr. Koch, referring to these seedlings in the pages of a contemporary, says:—"I am convinced that at the time of year at which they bloom there are no more beautiful or more useful plants than these hybrid Hellebores, which originated in the Berlin Botanic Gardens." Messrs. Ant. Roozen & Son, Overveen, near Haarlem, who will offer them in the autumn, have kindly sent us the following details respecting them:—No. 1. Flowers beautifully

Double-flowered Branched Larkspur (see p. 459).

formed, 3 inches in diameter, bright dark purple and rose colour, with numerous carmine-red streaks; a rich and early variety. No. 2. Remarkably fine flowers, good in form, stately, and raised well above the leaves; petals finely cut and curved, very large, often 3 inches in diameter; colour, pale brown and purple-rose, with numerous sharp, dark carmine-red spots; a showy variety. No. 3. Flowers excellent in form and attitude, large and abundant purple-rose. No. 4. Smaller flowers, but in other respects the same as No. 3. No. 5. Flowers large and flat, fine

in form, 3 inches in diameter, colour snow-white, a fine kind. No. 6. Flowers pure white, from 2 to 3 inches in diameter, showy and effective. No. 7. Finely-formed pure white flowers spotted with red. No. 8. Flowers large, finely-formed, snow-white spotted with red; a fine variety. No. 9. Like the last. No. 10. Flowers white spotted with red, like seedling No. 7. *Præcox major*, flowers snow-white, earlier than all the others, and very free flowering.

Hardiness of *Primula japonica*.—This *Primula* has proved quite hardy with me throughout the winter, and it is a very effective spring bedding plant, but requires to be massed to produce the best effect, as, unless the plants have formed good strong crowns in autumn, they will only produce one spike of bloom the following spring. Your correspondent, "H. T." (p. 373), will find that the foliage of this *Primula* always dies down in autumn when the growth is matured (either in pots or planted out), and it will remain dormant for a considerable time. It is capable of withstanding heavy rain and wind without being staked, the flower-stalks themselves being as strong and wirey as many stakes that could be found, and therefore the unsightly appearance of the latter may be avoided altogether. It receives the same treatment with us as the other spring bedding plants, and yet I hope to see our borders and shrubberies glowing through the spring months with the brilliant hues of this lovely flower.—R. GREENFIELD, *Priority Gardens, Warwick.*

Culture of the Flame *Nasturtium* (*Tropæolum speciosum*).—Your correspondent, "S. R.," inquires (see p. 395), if this beautiful climber will answer on a low terrace wall facing due south. We find in Scotland that it succeeds in any aspect; and the longer it is established, the more effective it becomes. A cool, but genial soil is probably the main condition of success, and it certainly appears to prefer a moist climate. Here, in the south-west of Scotland, it increases very rapidly, and is a great ornament to shrubberies and Ivy-covered walls, both from its graceful foliage, vivid blossoms, and bright blue berries. I would recommend your correspondent to get his plants well established in pots, and then to plant them out in a cool and somewhat moist border, where they may climb on shrubs, a hedge, an Ivy-covered wall, a trellis, or on any other kind of support. They will not make much show the first year; but it will be seen in the following season whether they can take care of themselves. If so, well and good; "S. R." will have made a valuable addition to his hardy plants. If not, it is not worth taking further trouble in the matter, as this plant is nothing if not luxuriant.—SALMONICEPS.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Growing the Edelweiss near London.—As there was some discussion some time ago in your columns about the possibility of growing *Gnaphalium Leontopodium* (Edelweiss) in the London suburbs, I would mention that a plant of it, sent me two years ago by Messrs. Backhouse, is now growing strongly and has fine flower-heads on a little rockery where London fogs play havoc with many Alpine plants.—J. R. DROOP, *Stamford Hill.*

***Daphne Cneorum*.**—This *Daphne*, though well known, is not nearly so often met with as it ought to be. It succeeds planted out in ordinary soil, and in pots is well adapted for conservatory decoration. Its branches layer themselves, and only need to be taken off and planted or potted. Its rosy flowers are pleasantly scented.—J. MURR.

A Vigorous *Marechal Niel* Rose.—Last autumn I budded this upon an old-fashioned wall Rose, and late this April it started into unusually vigorous growth. It has already grown 4 feet in height and is still steadily progressing at the rate of $1\frac{1}{2}$ inches per day. One leaf petiole measures $10\frac{1}{2}$ inches in length and $8\frac{1}{2}$ inches across the two centre leaves. The largest single leaf measures 5 inches by $3\frac{1}{2}$, and all the foliage is equally vigorous. Is not this extraordinary, and may I expect flowers of proportionate size?—W. A., *Gloucester.*

Maiden-hair Fern in the Isle of Man.—On the 4th ult., I found *Adiantum Capillus-Veneris* growing in moderate abundance on the west coast of the Isle of Man, near the village of Glenmayo. The young fronds were just peeping from the opening in the rocks, some 10 to 15 feet above high-water mark. I mention this fact because I have noticed that several writers, in alluding to this Fern, have confined its occurrence to the more southern parts of England and Ireland.—H. J. MARSDEN, in "Science Gossip."

***Anemone japonica alba*.**—In your interesting article on the Windflowers (p. 423), there is a mistake which ought to be rectified. *Anemone japonica alba* is said to be synonymous with A. J. Honorine Jobert, which is not correct, as the latter is a very superior flower to the other; the mistake as to the identity of the two occurs, however, in more than one herbaceous catalogue. It may be also interesting to know that there are two varieties of *Anemone* (*Hepatica*) *angulosa* in cultivation, one having broader petals than the other. The engraving of this species represents the inferior sort.—R. P. B. [*Anemone Honorine Jobert* is a sport from A. *japonica*. Its origin has been fully given in our last volume (see p. 498).]

Saving Dahlias from Slugs.—As the time for planting Dahlias is at hand, let me entreat your readers to beware of slugs. After planting, press close the earth near the stems, that an enemy may not remain concealed to bark the stem all round and kill the plant. Dust a little lime close to the stem; it is of no use elsewhere. Repeat the dose after every shower until the plants grow beyond the power of their enemies. Sow a little Lettuce seed—say a dozen seeds—round every plant; the slugs will feed on them and not touch the Dahlias. By-and-bye, hoe out all but one of the Lettuces, which will be useful.—GEORGE RAWLINGS, in "Gardeners' Magazine."

THE INDOOR GARDEN.

TUBEROSES IN MID-WINTER.

To have Tuberoses in at Christmas, and on New Year's Day, the following course is pursued in the United States, where Tuberoses are admirably grown:—By the 20th of August they are potted into 4-inch pots, containing a composition of two-thirds strong loam and one-third old rotten manure. They are then planted out of doors in a frame, as close as they will stand until the end of September, when the centre table of a span-roof house is bored with a number of holes to let up the warm air from underneath, and the Tuberoses are planted out on this. It is necessary to have three or four hot-water pipes underneath the table, and the compost ought to come, if possible, from an old pasture. To every two barrows, one barrow of old hotbed manure is added, the whole being well mixed together, and then placed upon the table to a depth of 5 inches, and well pressed down with the feet to give solidity. The Tuberose does best on a heavy rich soil. The bulbs are then turned out of the pots, and planted in rows 6 inches apart, and 6 inches from plant to plant, and thoroughly watered with the hose. The plants are well syringed, and, on the first appearance of frost, a moderate night temperature of, say, 60° should be maintained. By the 6th of November, the plants will be well established, when the night temperature may be increased to 70°, and abundance of moisture used, the path of the house being flooded at night. Sulphur, worked into the consistency of thick paint, is put on one of the hot-water pipes, as a preventive against red spider, the great enemy of the Tuberose. If the plants have been managed properly, they will commence to flower by the middle of December. At Christmas, they command from £1 to £1 12s. per hundred florets, each plant or bulb producing from thirty to forty florets at these prices. The following practice is usually adopted, and is, I think, the most practicable for the spring crop:—A hotbed, or better still, a pit, is prepared in a similar way to those for Melon and Cucumber growing in England. As soon as the rank steam is off, 3 inches of coal ashes are put on, and the bulbs potted as previously directed, selecting those that are thick at the neck. Some think a very large bulb is best; but I think those of medium size are preferable. First-class bulbs sell at £10 per thousand; those of second quality, £7 per thousand. The pots are plunged to the rim in the bed, and there is no danger of their rotting from the heat, which they will bear well. Linings are added as soon as the surface heat declines, the night temperature being kept at 60° and the pit covered up well at night, mats and shutters being used; in a month or five weeks, they will have their pots well filled with roots, have dense foliage, and they are then ready for the house. The first crops by this time are gone. Having planted out as before recommended, plenty of water must, as the spring advances, be given to the plants in the bed. Morning and evening a syringing must be given with the hose to prevent red spider. Should the plants come near the glass, they must be tied down. Thus treated, they will in part commence to flower by the end of April. The florets sell from 12s. to 16s. per hundred, and, by June 1st, they are down to 8s. per hundred. Even at these prices I have known £200 made of the plants grown on the centre table of one house, the table measuring 88 feet long by 6 feet wide.

JOHN HOWATT.

USES OF SPENT TAN IN GARDENS.

M. G. ERMENS, writing in the "Revue Horticole," makes known some of the results obtained by the use of this material in Paris. He has used it in his propagating-houses for several years, and when done with there it is further employed as follows:—In April numbers of plants, to be afterwards used for the decoration of the squares and parks, are removed from under glass to be hardened off and planted out in the end of May; others are re-potted, and plunged in beds under Thujas, part in tan and part in sand; each plot is 6 yards in length, $1\frac{1}{2}$ yards in width, and in each are placed an equal number of plants of the same kind, and under exactly similar conditions. The result has been, that by the end of June those which were placed in tan were very superior to those in the sand; the roots which, in every case were abundant, filled the pots, a circumstance that accounts for the vigorous appearance of the plants as compared with those placed in sand. At the end of May there still remained some sheltered beds at command; and the whole of them were filled with old tan, in which *Dracænas*, *Latania*s, *Chamærops*, *Begonia*s, *Curculigos*, *Aspidistras*, *Musas*, *Ficus*es, *Caladium*s, and various other plants were plunged. In autumn these plants were in remarkable beauty, and every fortnight or three weeks it was necessary to move the pots to prevent the too great development of the roots in the tan. It was also found that less

water was needed in the tan beds than those of sand during severe heat; the latter required three waterings a-day, whilst two were sufficient for the tan, and, ordinarily, only one—a fact which may be accounted for by the retentive character of the tan; the sand, on the other hand, allowing the water to percolate through it. In 1865 M. Truffaut's fine collection of Amaryllids came under M. Ermens's care, and he had an opportunity of again ascertaining the good effects resulting from the use of tan as a plunging material, for the Amaryllids placed in it produced plants of fine roots and flowered magnificently. Each year, when re-potting the Amaryllids, all the bulblets were preserved and planted out, care being taken to cover the whole with a layer of tan as a mulching, and, under this treatment, numerous roots soon made their appearance. The borders and clumps planted with Cannas were every spring mulched with tan to a depth of about 1½ inches, and with no great advantage to them. New tan was, however, never used, but simply the refuse of the forcing-houses.

Poinsettia pulcherrima Planted Out.—In America, old plants of this are cut back by the middle of April; if at all straggling, they must be cut in boldly. It is not necessary to have a portion of last year's wood; they will break no matter how low you cut back, and a neater appearance is given to the plants; they are then shaken out thoroughly and re-potted into 7 or 8-inch pots, the compost in which should be one-third fresh loam or heavy clay, one-third rotten manure, and one-third old Hops and manure passed through a coarse sieve. The plants should be kept in the house until they have well broken, when they are turned out-of-doors and plunged in ashes or sand to the rim. As soon as they fill the pots with roots they are re-potted into 12-inch pots or, if the plants be old and require it, into larger ones. By the end of June all the strong shoots at the top should be pinched; they give you two or three shoots, and, as a consequence, more bracts in the winter. By the 20th of September they are moved into the house, taken out of their pots, and planted out on the tables, either upright or laid on their sides in a sloping position. If the latter course be adopted the rays of the sun will soon bring them to an upright position. An abundance of air during the autumn months should be given; as soon as frost sets in, or during the early part of November, the night temperature should be 60° at night, and from the middle of November to Christmas this is increased to 70°. This temperature is necessary to open and bring the bracts to perfection. They are sold by the thousand to the New York florists about Christmas and New Year's Day, with an increasing demand for them from the western cities. They realise from £3 to £5 per 100 bracts. As soon as the flowers are all cut, they are taken up, and heeled in under the benches; the soil taken off the latter and used for potting bedding plants for spring sale. The Poinsettias are again cut back in April; the wood cut into short lengths, put in thickly in the hottest part of the propagating-house. As soon as they are rooted, they are re-potted, grown under glass all summer, and are sent to the Western States in the autumn. In the largest establishments, you can seldom, at any time, find many on hand, the demand being greater than the supply. Mr. Peter Henderson, of Bergen, is one of the largest growers of Poinsettias around New York, and he also devotes part of his establishment to the production of Rose-buds.—J. H.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Adiantum speciosum.—This is a very elegant Fern of semi-scandent habit, furnished with large tripinnate fronds, which frequently attain a length of 36 and a width of 21 inches. The whole of the pinnules are covered with dense short hairs, which give the foliage a woolly feeling when touched. This beautiful plant is very distinct from any Adiantum in cultivation, and has the peculiarity of being deciduous. It formed one of a collection of six new plants with which Messrs. Veitch won the first prize at the great exhibition of the Royal Horticultural Society in 1873, and it is in all respects a Fern worthy of cultivation.—B.

Succulents in Bloom at Sudbury House, Hammersmith.—I have thought that it might interest some of your readers to know that the following Succulents are now in flower here, viz.:—*Cereus pectiniferus*, p. *Hornarii*, *speciosissimus*, *leptopus*, *Mallesonii*, *flagelliformis*; *Echinopsis Schellhassii*, *oxygona*, *amena*, *Zuccariniana*; *Mammillaria polyedra*, *recurva*, *centricirra*, *glochidata*, *Wildiana*, *sphaeracephala*, *euberimana*, *polygona*, *villifera*, *meyacantha*, *Hystrix*, *mutabilis*, *Fischerii*, *centrispina*, *pyrocephala*; various kinds of *Phyllocactus*; *Echinocactus multiflorus*, *Wanderayii*, *Kochii*, *bicolor*, *myriostigma*, *mammillosus*; *Aloe nobilis*, and many species of *Gasteria*.—J. CROUCHER.

Panama Hats.—*Carludovica palmata*, the young, unexpanded leaves of which are so largely used at Moyobamba and Guayaquil in the manufacture of Panama hats, is called a Palm, but it is more properly a Screw Pine. It has no stem; the leaves are long and on slender petioles, springing from the ground. They are about 2 feet long, fan-shaped and four-parted, each segment being again ten-cleft; so that when folded in venation, each segment on its own rib, there are eighty layers in a young leaf. It occurs only on the slopes of the Andes.

EDIBLE CACTI.

AMONG the various families of plants, the Cacti would, at first sight, be considered the least useful in an economic point of view, however singular and characteristic they may appear. And yet even these grotesque and spiny plants are not without their good uses to man. To say nothing of *Opuntia tuna*, *O. coccinellifera*, and *O. Hernandezii*, being the chief support of the useful Cochineal insect, and of their forming such admirable, impenetrable, and unflammable hedges in tropical countries, their edible uses are not to be overlooked. A dye can be prepared from the pulp of several species. Among the foreign fruits occasionally imported are small quantities of the Barbary Fig, as it is sometimes termed, although usually spoken of in the tropics as the Prickly Pear. The fruits of many other Cacti are, however, edible; and a brief notice of some of these may prove interesting. We will commence with the most common, *Opuntia vulgaris*, the fruit of which, from Algeria, and other parts of the Mediterranean and the West Indies, reaches Covent Garden, but seldom or never in perfection, so as to give any idea of its true flavour; and, moreover, we have numberless fruits of our own temperate climate which are far preferable. It is, however, in Italy that this fruit is chiefly appreciated. It formerly furnished one of the principal food substances in the Canaries. In Sicily, *Opuntia Ficus indica* is eaten, and widely cultivated, especially in the territory of Caltagirone, in the province of Catania. Of late years, it is cultivated there in rows as in Palermo; and there were, some ten years ago, upwards of 10,000 acres under culture with this Cactus, chiefly alone, or mixed with the Olive. The reason for this extended culture is the increasing demand for the fruit, both in town and country. At the period of their ripening, that is from November to January, the citizens assemble after dinner in the faubourgs of Santa Maria, of Fontanelle and St. Bartolomeo, to proceed in company to enjoy themselves by a repast of these delicious fruits. On Sundays, also, whole bands of artisans will proceed to the farms in the vicinity of these faubourgs to purchase and consume them. A couple of acres of land, if within a mile or a mile and a half of the town, yield an annual return of nearly £16 from this fruit.

A correspondent of one of the daily papers, writing recently from Corsica, states that the fruit is as much relished there. "It was an amusing sight just now to see a mother feeding her four children, all sitting on their haunches in open air, from a basket of Barbary Figs. I was puzzled at first at the gloves, the pocket-handkerchiefs, and the evident desire to clean the fruit of every particle of rind; but, happening to try one myself, I found that every hair of the soft, furry-looking substance outside was as sharp as a needle, penetrated fingers, lips, and tongue. We are taught by experience; and though Barbary Figs are sold at ten a penny, I shall not be inclined to try them again."

There are three or four varieties of this Cactus known in the locality—1, one with yellow fruit; 2, one with white fruit; 3, one with red fruit; and, lastly, one without seeds. It flowers in May and June, as does also another species; *O. amyclea*, Tenor., of which the fruit is also edible, but is less cultivated. The two first-named varieties are those which are chiefly grown because they are more productive, and the fruit is sweeter and larger. They are always most esteemed by the customers, and hence there is a continual increase of the demand for those Figs with yellow and white pulp. The retail price necessarily varies with the season and the abundance of the crop. In the month of September the earliest fruit will sell about a dozen for a penny, in October twice that quantity may be had; and, at a later period of the season, in December and January, their value will run up again to about six for a penny. With respect to keeping during the winter, those with yellow and white pulp hold also the first place. They may be preserved to the end of February on a layer of straw or hay, or on tiles if not removed from the branching leaves. In this way they may be kept good even till the end of May by covering them with hemp stalks or tow, or paper to protect them from frost and the attacks of insects. These fruits, which are largely consumed by the labourers when ripe, must necessarily be wholesome, as they contain much mucilage and sugar; they are eaten either alone or with bread. They cannot be successfully made into marmalade, as the heat is against it. The skin of the fruit is given to domestic animals, horses, mules, and asses, either alone or mixed with straw or hay. The spoiled fruit serve to fatten pigs, who are led about with a cord attached, to feed on those fallen to the ground. Alcohol is obtained from the refuse fruit by a rude process. They are first boiled, and then submitted to pressure to extract the juice, which is left to ferment in a wooden vat for about six days. It is then distilled, and the unpleasant odour removed by filtering through charcoal. The refuse fruit only cost about 1s. 3d. per cwt., and these give 50 per cent. of their weight in juice, and this, when submitted to the distillation, yields 2½ per cent. of spirit. The two varieties with white and yellow fruit sometimes present

examples of hybridisation. The variety with the scarlet fruit is cultivated with the others, but only in small numbers, as the pulp stains the lips in eating. M. Labouret, in his "Monograph on the Cacti," states that this variety is found without seeds, but this is not so in Sicily. The expense of cultivation is very slight. The plant requires no manure, but merely a little loosening of the soil annually, in December, at an expense of about £1 per acre. There are usually other crops raised between the rows of Cacti, either Wheat or Barley.

The fruit of *O. Engelmanni*, *O. vulgaris*, *O. camanchica*, *O. Rafinesquii* (the most northern of all the species), and *O. occidentalis*, is much eaten by all of the Indians of New Mexico, Arizona, California, and Utah, under the common Spanish name of "Tunas;" great quantities being dried for use in the winter. The fruit are large, and of a bright red to purple colour; of a rather pleasant, sweet, and somewhat acid taste; and have thin skins, and rather large seeds, which are discarded. The skin is studded with bunches of very fine downy spines, which the Indians brush off with a bunch of Grass. The Apaches use wooden tongs to gather the fruit, to prevent being scratched by the spines or thorns of the plant. The Pawnees and Papajoes dry the unripe fruit of the *Opuntia* for future use, to be cooked with meal and other substances. The fresh unripe fruit is often boiled in water from ten to twelve hours until soft; then, being allowed to ferment a little, it becomes stimulating and nutritious. Some Indians roast the leaves or branching stems of the *Opuntia* in hot ashes, and, when cooked, the outer skin, with the thorns, is easily removed, leaving a slimy, sweet, succulent substance, which is eaten. A San Francisco paper published recently an interesting account of the economic applications of some of the Cacti in the north-west parts of America. The giant or monumental Cactus (*Cereus giganteus*) is a noted plant of the barren hills of Arizona. It grows 25 to 50 feet high, and 4½ feet in diameter, is deeply ribbed, and covered with long black spines. Its fruit is Pear-shaped, of a greenish-yellow colour, with a few small spines scattered over the surface, which fall off as the fruit becomes thoroughly ripe. The fruit is borne upon the highest part of the plant, and is usually gathered by means of long hooked sticks. The interior of the fruit is of a beautiful red colour, and looks tempting; the rind is pulpy, porous, juicy, and sweet; the pulp is very palatable, and is full of small black seeds, which are also eaten, reminding one of Figs, the only difference being that it has more moisture. The seeds are indigestible, unless well masticated. The Indians of Arizona, Sonora, and the southern portion of California consider this one of their greatest luxuries, and, as long as the fruit is obtainable, care for nothing else. To dry this fruit as a preserve, the seedy pulp is placed between the soft inner sheathing husks of the Maize-cob, the ends of which are tied, and it is then dried in the sun for winter use or trade. It is also put into earthen pots when fresh, secured from the air, and sold in the settlements. It retains its sweetness for a long time. A clear, bright-brown syrup is expressed from the pulp, and sold in gallon jugs, also made by the Indians, at from 2 to 5 dollars. The Papajo Indians are the largest producers of this syrup. The Pimo Indians of the Gila river annually prepare a wine from this fruit, called by the Mexicans *tiswein*, by taking the first pulp or the syrup, and mixing with it a certain quantity of water in earthen vessels, and expressing it to the same for some time to ferment, after which it is fit for drinking. It is highly intoxicating, with the taste and smell of sour beer; but some time elapses before its stimulating effects are felt. When the wine is ready for use, the Indians celebrate their annual drinking festival. These gatherings are anxiously anticipated for months, and expeditions, which have been planned against the Apaches while under the influence of drink, are then carried into execution. It is a clear amber colour, and is in every respect superior to much of the wine on sale in California.

Thurber's Cactus (*Cereus Thurberi*) is commonly called Pitahaya by the Mexicans. It grows in the Papajo Indian country, on the borders of Arizona and Sonora 18 to 20 feet high, and 4 to 6 inches in diameter, and bears two crops of fruit for years. The fruit is of the size and shape of an egg, and is thickly covered with long black spines. As it ripens it becomes tinged with red, the spines fall off, the fruit splits open and exposes a rich red, juicy pulp, with small black seeds. This is decidedly better fruit than that of the *Cereus giganteus*, but it is used in every respect for the same domestic purposes. The Papajo Indians, in transporting earthen vessels filled with syrup or preserves made of the fruit to market, cover their jars with a thick coating of mud, which renders them less liable to break in handling, and at the same time keeps the contents cool, and prevents evaporation, the crockery used being very porous. The fruit is eaten in enormous quantities, and, being very nutritious, the consumers quickly acquire an extraordinary increase of bulk. In making wine or syrup the seeds are easily separated from the pulp by the use of water. They are carefully collected, dried, parched,

and pulverised, after which process they are digestible and nutritious.

The singular species of Cactus (*Echinocactus Wizlizeni*), commonly called *boiznacha* by the Spaniards, being 20 inches, or more, in diameter, a section of the stem is often employed as a cooking vessel. The seeds are small and black; but, when parched and pulverised, make good gruel, and even bread. The pulp of the fruit is rather sour, and not much eaten. Travellers, in passing the Cactus wastes, often resort to this plant to quench their thirst, its interior containing a soft white watery substance of slightly acid taste, which is rather pleasant when chewed. It is a common sight to see on each side of the road these plants with a large perforation made by the thirsty traveller. An Indian, when travelling, and wishing to make a meal, selects a large plant, 3 or 4 feet long, and 2 feet in diameter, cuts it down, and hollows it out, so as to form a trough. Into this he throws the soft portions of the pulpy substance, which surrounds the central woody axis, and adds meat, roots, seeds, meal, fruits, or any edible thing on hand. Water is added, and the whole mixed together. Stones are then highly heated, and dropped into the mixture; and, as they cool, are taken out, licked clean, re-heated, and returned to the cooking vessel, until the mixture is thoroughly boiled. This is a favourite dish with the Yabapais and Apaches of Arizona. The Papajo Indians pare off the rind and thorns of large species of this Cactus, letting it remain several days to bleed, when the pulp is pared down to the woody axis, cut up into several pieces, and boiled in syrup of the *Cereus giganteus* or *Cereus Thurberi*. If a kind of sugar made by the Mexicans is attainable, it is employed instead of the syrup, thus forming a good preserve. These pieces, when taken out of the liquid and dried, are as good as candied Citron, which they much resemble in taste.

P. L. SIMMONDS.

PELARGONIUM QUEEN VICTORIA.

THE races of Pelargoniums which we have long possessed might be thought sufficiently numerous to embrace all the novelties likely to occur among these plants for some time to come. Such, however, is the extent of variation among seedlings that, now and then, distinct forms crop up which are themselves likely to form the centres or parents of small groups. Such is the case with the Pelargonium which we now figure. It is vigorous in habit, and blooms most profusely, its flowers being borne in dense globular trusses, well elevated above the foliage. The individual blooms are also large, and nearly circular, each petal being elegantly crisped, or frilled, a condition which gives much fulness to the flowers, most of which have six petals instead of five; and then there are three upper segments deeply blotched with blackish-maroon, instead of two, the usual number. The lower segments, as will be seen, are of a brilliant orange-scarlet or vermilion colour, which the white margin sets off to advantage; and there is a distinct white eye which still further adds to the brilliancy of its surrounding colour. As a decorative plant for the greenhouse or conservatory, it is destined to become a general favourite, especially as its semi-double flowers are more durable than those of the ordinary single kinds. This remarkable and handsome Pelargonium has been sent out and is now being distributed by Mr. Bull, at whose establishment in the King's Road, Chelsea, we have seen it beautifully in flower, together with a darker-coloured variety, named Beauty of Oxtou, another fine kind, similar in habit, and one which also bears frilled white-edged flowers.

B.

Roots in Drains.—In a paper recently read before the Edinburgh Botanical Society, some curious cases were cited of the entire occupation and stoppage of drains by roots of trees. In one instance a 2-inch pipe, with sockets, laid in an orchard a foot below the surface, was completely filled with the roots of an Apple tree. In another, a root had entered a lead pipe and grown and branched into numerous fibres which filled the pipe for a considerable distance. The strangest case was where a Willow growing near a dam had sent roots 25 feet beneath a road, and penetrated a large leaden drain-pipe 7 feet below the surface, and stopped it. The pipe was taken up and cleared, and the tree cut down. The drain was relaid, but some time afterwards was again stopped. It was then found that the stump, which had sprouted, had sent a mass of rootlets into the drain, which had filled the pipe solidly, although their connection with the tree was only by a single fibrous rootlet.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Lettuce.—Make successional sowings of Lettuce, and at this season it is a good practice to draw shallow drills 12 or 15 inches apart, and to sow the seeds in the bottom; the plants can thus be well soaked with water when they require it; advancing crops will be benefited by the application of manure-water. Early crops of the Cos varieties should, as they approach maturity, be tied up with bast, which is of much assistance, even in kinds that are the most disposed to turn in their leaves and blanch naturally, and, moreover, it improves the quality. Amateurs who have not had much experience in Lettuce growing are apt to tie the ligatures too tight, which bruises the leaves and causes them to rot. All that is required is to draw the leaves together with the hand and tie them sufficiently close to exclude light. Keep the surface between advancing crops frequently stirred with the hoe; and, where the soil is of a heavy retentive nature, and was at all wet when dug, its condition will be greatly improved by forking it over to the depth of 6 or 8 inches, care being taken not to disturb the roots of the growing crops. Ground so treated becomes pulverised by the action of sun and air, and is in a better condition for the roots to penetrate later on as the different crops advance in growth. Small Salads should be sown every ten days or, at all events, every fortnight; otherwise, the supply will be interrupted. When the weather is hot and dry let such plants, and especially Radishes, be watered, or they will be tough and stringy. A small sowing of Walcheren Cauliflower should now be made.

Planting Brussels Sprouts.—These should now be planted; and in order to obtain a full crop, the plants ought to be got in when they are large enough to handle. The weight of produce will thus be double what it would be if the plants were long confined to the seed-bed. Brussels Sprouts do not require so much room as winter Broccoli; but they must by no means be planted too closely, or they never attain the vigorous hardy condition which alone enables them to stand a severe winter. The nature and condition of the soil in which they are grown has much to do with the space they should occupy. In good well-manured land they should be put in 2 feet 3 inches apart each way; in shallow poor soil, they may be placed 6 inches closer, both in and between the rows. Move them, so far as possible, with their roots entire; and, if the weather be dry, give them a good watering.

Apricots, Peaches, and Nectarines.—Apricots are often much infested with a small caterpillar that eats the leaves, and this, if allowed to go unchecked, does serious harm, rolling itself up much in the same way as the rose maggot; it is, however, easily detected. The trees should be gone over as soon as it makes its appearance, and the invader crushed with the finger and thumb. If the fruit has not been sufficiently thinned, at once remove more, not allowing a greater quantity to remain than the trees can support and mature thoroughly, otherwise the produce will be small and comparatively flavourless. See that no trace of Aphides has been left on Peaches and Nectarines, or they will still spread, and inflict serious damage. As regards thinning, the remarks made respecting Apricots apply to these trees also. Let the strength of each individual tree be taken into consideration, such as are strong and vigorous being naturally able to support a greater weight of fruit than others in a weaker condition, although the latter generally set the greatest quantity. Over-cropping not only gives inferior produce, but permanently injures the trees, if continued for a few years, so as often to necessitate their removal. In many cases, the situation is blamed for this state of things, whereas, if they were sufficiently supplied with water, and not over-cropped, they would live and fruit up to a vigorous old age. Watch closely for mildew; if it makes its appearance on the leaves or points of the shoots it will quickly attack the fruit. As soon as a trace of it is found the affected parts must be dusted freely with sulphur; the old-fashioned sulphur-puff is the best and most simple instrument to use for this purpose. If we have a continuance of dry weather, and the border in which these trees are grown is cropped with anything else, such, for instance, as Strawberries or summer vegetables, it should not be forgotten that the latter materially assist in extracting the moisture from the soil, and necessitate the application of more water, which must be given without stint. Before it is applied in quantity the surface should be stirred with a fork or hoe to a depth of a couple of inches to admit of its getting down to the roots; in dry situations, where water has to be given, it is often necessary to repeat this loosening process, as the soil gets baked on the surface and causes the water to run off. Do not allow the leaves to overhang the fruit, which should be fully exposed to the sun; but, in this operation, do not go too far, as the extent to which the leaves of Peaches and Nectarines are often destroyed, where excessive disbudding is practised, renders it utterly impossible that the trees should possess their

wanted vigour. It is necessary to thin out the shoots, so that all allowed to remain will have a full share of air and light to strengthen and mature the young wood for next year's fruiting; but all beyond this is injurious, as every leaf removed proportionately curtails the formation and power of the roots.

Cherries and Plums on Walls.—These are also very subject to caterpillars; and, when they appear in numbers, they do much harm, not only disfiguring the leaves, but absolutely injuring the trees. There is no means of destroying them, except by going over such as are affected, and crushing them. This should always be done as soon as they are discovered, as the longer they are allowed to remain, the more difficulty there is in their destruction. Cherries are also subject at this time of the year to the attacks of black fly on the young shoots. If this pest is taken in time, before they have become dispersed over the trees, and while confined to a few of the shoots, they may be easily destroyed by dipping those that are affected in tobacco-water; for this aphid it must be strong, as it is much more difficult to kill than the green species.

Flower Garden.—Bedding plants that have been confined in small pots, with the roots much matted before they were turned out, require a considerable amount of water in dry weather, until they have had time to lay a firm hold on the soil, so as to draw the moisture they require from it, and, unless well supplied in this respect, suffer seriously. See that all are pegged down as growth progresses; otherwise they are sure to be injured by the wind. This training is necessary to ensure the beds being well furnished in the least possible time. Daisies, Aubrietias, Alyssums, or similar plants, which, on account of their being in flower at the time the principal bedding plants were put out, were not then removed, should, as they get shabby, be transferred to the reserve ground, and their place taken up by those subjects that I before advised should be kept in readiness for the purpose. Look well to such plants as Verbenas, Asters, and others that are similarly subject to the attacks of green fly; for, if it is allowed to remain upon these plants, it will, in a short time, spoil them for the season. Even when all reasonable care has been taken that they were clean when turned out, it frequently happens that they become affected afterwards, in which case there is no remedy but a thorough washing with tobacco-water, or dusting with tobacco powder.

Herbaceous Borders.—Numbers of plants will now require supporting by sticks and ties. This should always be carried out as soon as it is needed, or the plants get broken down and disfigured by the wind. To do the work in a proper manner requires some taste and consideration as to the nature of the plants. Nothing is more common than to see the sticks and matting brought so prominently into view, as to make it appear that they, and not the plants, were intended to be looked at; or to see each plant bound up as tight as a Birch broom, with an injurious effect, both as regards their health and natural appearance. Never use more supports than are absolutely necessary, and keep them as much out of sight as possible.

Pits and Frames.—As the frames are now cleared from bedding plants, the latest-sown Melons should be put in them; these will come in late in the season. The beds need not now be made so substantial as was necessary earlier in the season; if a good supply of last autumn's leaves are at hand they may be made of at least one-half of this and well-prepared dung. Three feet in depth will be enough now; beds of this description will be sooner cool enough to receive the plants than those recommended earlier in the season. In localities not favourable to the growth of Tomatoes, or where a difficulty has been experienced through attacks of the disease with which this vegetable has of recent years suffered, it would be advisable to grow some in frames. If the plants are put into 12-inch pots and plunged in the ground, and the frames elevated on bricks so as to give increased head room, good crops may be secured. The principal thing to be observed in their culture is to keep the plants sufficiently thinned and well tied out, not allowing them to suffer for want of water, and giving enough air to induce stout growth.

Flower Garden and Pleasure Grounds.

The principal operation connected with this department, viz., that of planting the various beds, borders, baskets, and vases, with their summer occupants, will now in most cases be finished; and it is, more than ever, necessary that order and neatness should be scrupulously maintained. Lawns, at this season, are often much disfigured by Daisies; and, during dry weather, when Grass does not grow very rapidly, the Daisy rake will be found useful. Plantains, and other broad-leaved weeds should now be eradicated, if possible; and this may be done by cutting their heads off with a sharp knife, just under the surface of the soil, when they may be drawn out, and the space they occupied will soon be taken possession of by the finer Grasses of which the lawn should consist. Box edging may now be cut. It is seldom advisable to do this sooner than about the present

time, as the slightest frost occurring soon after the operation has been performed, will inflict so much injury upon them as to make them look unsightly for some time afterwards. Tie up Dahlias and Hollyhocks, as they continue to require that attention. It is always advisable to place stakes to such plants as soon as they are planted, or before their roots have had time to extend themselves, as driving large stakes into the ground at a later period is apt to injure their roots. Bulbs of Hyacinths and Tulips may now be taken up and stored away. Peg down the shoots, and regulate the development of such plants as Verbenas and Petunias, in order to get the surface of the beds covered as speedily as possible, when less water will be necessary than at present. Regulate also the growth of climbing Roses, Honeysuckles, the new and beautiful Clematises, all of which are worthy of a place in every flower garden. Where stock of the various kinds of spring bedding plants was not divided or otherwise increased when taken from the beds, that may be done now, or as soon after this time as possible. Such kinds as the following may be divided, if desirable, to an almost unlimited extent, viz., *Viola cornuta* and *lutea*, *Aubrietia deltoidea*, *deltoidea variegata*, *Campbellii*, *greca*, &c.; *Myosotis dissitiflora*, *Omphalodes verna*, *Phlox verna*, *Gentianas*, *Hepaticas*, hardy *Primroses*, *Oxlips*, &c. The two last named will now be out of flower; but the best varieties should have been marked, and should now be increased accordingly. All these, together with the various double and single Wallflowers, should have what little attention they may require in the reserve garden, which is also the proper place to test, during the first season, the numerous novelties in the way of bedding plants, which are annually introduced, and which are generally sent out in the form of very small plants in May. As soon as they are received they should be re-potted, and have every necessary attention; and, where they have been well treated, such plants will now be sufficiently established to be planted out in this department, in order that they may furnish cuttings at as early a period as possible, and also afford opportunities of forming correct opinions as to their merits and adaptability to the purposes for which they are recommended. Wherever rival leaders may exist upon young trees, more particularly upon those belonging to the Coniferous family, the strongest and best placed should be selected, and all others carefully removed. An undue tendency to lateral extension is frequently exhibited by young trees of this description, and this should also be checked by stopping, or slightly cutting back all strong side-growing branches, with the view of directing the energies of the tree to the production of upward growth.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Indoor Fruit Department.

Vines.—All young Vines in pots should now be growing freely, and manure-water may be given them with advantage at every alternate watering. Red spider is the only pest which is liable to damage them after this time; but frequent and copious syringings will keep the foliage perfectly clean. Those Vines that are intended for planting out when ripe should be stopped as soon as they are 4 or 5 feet high, as the lowermost buds ripen and develop better on a cane of this length than on one a few feet longer. No benefit is to be derived from growing a great length of cane for planting, as the top, which is generally the best part of it, is ultimately cut off. Fruiting canes may be allowed to grow until they are 6 and 7 feet long before they are stopped. The growth which breaks away from the top bud after being stopped should be permitted to make a couple of joints, above what will be the principal cane. When free-growing Vines of this kind are kept closely pinched at the end, the buds further down frequently burst and grow, and this interferes with the production of good wood. Never grow any kind of young Vines too closely packed together, or in any position where they are deprived of light, or where the sun's rays cannot get at every leaf. The back wall of a lean-to unshaded house is most suitable for them in summer; a house with a great deal of fire is unnecessary. The more hardily Vines are grown, especially those for early forcing, the less difficulty will there be found in obtaining the best results. Where mildew has been troublesome, an abundance of fresh, dry, warm air, which can now be freely admitted to Vineries on suitable days, will check its further progress. To eradicate it thoroughly, damp the affected parts, and dust them with sulphur while wet, and the present is the best time for doing so.

Pines.—Where suckers on Queens and other varieties are likely to be very small, when taken off in July, all the leaves should be cut back to within 2 or 3 inches of the stock, as soon as the fruit is cut, which enables the suckers to obtain all possible benefit through the roots. This course has also the advantage of letting more light and air about the suckers, and making them more symmetrical in form than could possibly be the case when they are crowded round with leaves. Water sparingly after the leaves are cut, but do not allow the atmosphere to become too dry.—J. MUIR.

Peaches.—Early Peaches are now ripening fast under the present warm and favourable weather, and an abundance of air must be given to flavour and colour the fruit. The trees should still be syringed carefully twice a day, to keep the foliage in good health, and as a preventive of red spider; at the same time, no water from the syringe should lodge in the hollow of the fruit around the stalk, as it will cause decay, and the fruit to drop off prematurely. On no account allow the trees to suffer for want of water at the root; this should be attended to continuously until the wood is ripened, especially in light porous soils. The young wood should now be tied in to allow the fruit to be benefited by sun-light. When the space between the wires and the glass is filled up by young growth, the under foliage gets too much shaded; it also obstructs a free circulation of air over the fruit. When the latter has been gathered, the trees may be still further thinned of this year's bearing wood, to allow room for laying in the current year's shoots. Attention should be paid to the gathering of the ripening fruit; the experienced eye will readily detect such as are ready to pick.—W. D. C.

Hardy Fruit.

Apricots, Peaches, and Nectarines should now be finally thinned; were this always completed before stoning commences there would be fewer complaints of fruit dropping at the stoning period. It is the excessive demand for nourishment made on the trees by the fruit at this critical period that causes it to drop. The young growth or shoots intended for bearing next year should also be laid, tied, or nailed in, as the case may be, in doing which see that each shoot has sufficient space, that all the sunlight and air may have free access to every bud; well-ripened wood and buds are indispensable to successful fruit culture. Now that all danger from frost has passed, pinch or cut off all superfluous growth from Pears, Plums, and Cherries, and apply the usual remedies for the destruction and prevention of aphides and blight of all kinds. Cordons and espaliers of Apples and Pears should now have the fruit thinned, the shoots pinched back to three or four eyes, and the leaders tied to supports. For nearly all kinds of fruit summer pinching is preferable to winter pruning, a fact that is now in a way of being fully recognised. Strawberry runners, whether intended for forcing or planting out, should be layered as soon as the young plants are formed. For the former purpose early runners are essentially necessary, that a long season may be had for the full development and ripening of the crowns, without which it is useless to expect successful results. Blackbirds and thrushes attack the fruit as soon as, and sometimes before, they change colour, and it is advisable, therefore, to protect it with netting as soon as it begins to turn. Water effectually when necessary.—W. WILDSMITH, *Heckfield*.

Orchids.

In June, these plants will require much the same treatment as they did last month. It will be necessary to supply them regularly and plentifully with water, especially those that are well rooted. Where the Sphagnum Moss does not appear healthy, and has become sour, fresh material should be substituted. The *Cattleya Mossiæ* section, that has finished flowering, and require it, should now be potted. They do well in a mixture of rough fibrous peat, mixed with coarse silver sand and crocks. *Dendrobium Bensoniæ* and *D. Devonianum* will also require potting. These grow in equal parts of fibrous peat and Sphagnum Moss, with coarse sand and crocks. They should have a night temperature of 70°, and this should be allowed to rise as high as 90° by day with sun-heat. *D. infundibulum* does well in the temperature of a *Cattleya*-house; after potting, allow 65° at night, and this should be permitted to rise to 80° by day with sun-heat. Care should be used in watering *Lycastes* that have begun to make growth; the water should not be allowed to settle in the young shoots till the bulbous part is formed. *Phalænopsis grandiflora*, and others should be plentifully supplied with water, till they have finished their growth. They should be subjected to a temperature of 70° by night, which may rise to 85° or 90° by day with sun-heat, and should be thickly shaded from June to August. They will be much improved by having their leaves sponged frequently with water. *Dendrobiums* that are growing freely should be regularly sprinkled with water, or they will be infested with red spider and thrips, which, if allowed to increase to any extent, will injure the growth for the entire season. *Cypripediums* that are growing freely should be watered with weak liquid manure twice a week. *Odontoglossum Roezlii* and *O. vexillarium* do well in a temperature of 65° by night and 80° by day with sun-heat. Keep *Masdevallias* and *Disa grandiflora* abundantly supplied with water, and also use weak manure-water twice a week. The floor and benches of Orchid-houses should be sprinkled two or three times a day with water during the present and two following months; as the greater portion of Orchids will be making growth, this treatment will benefit them much.—E. CULLEY, *Ferniehurst*.

THE KITCHEN GARDEN.

ARRANGEMENT AND EXTENT OF THE KITCHEN GARDEN.

THE kitchen garden is an indispensable adjunct of every mansion, to which it should, to some extent, be proportionate in size; and to serve its purpose thoroughly its situation and arrangement should be well considered. This is not a needless recommendation, for grave errors are often committed in this respect. I am acquainted with several very extensive kitchen gardens, laid out within the last few years, in which neither a practical knowledge of kitchen gardening nor judgment in the selection of a site have been kept in view,—mistakes only discovered when it was too late. Sometimes a bad situation is chosen, and a good one narrowly missed. Such an instance came under my notice lately, where the 8 or 10-acred enclosure was pushed forward upon an unequal, precipitous slope, that an expensive range of hothouses might, it seemed, be hid from view behind, and one of the finest sites that could be found for a range of houses missed inside the walls of the garden, where one would naturally expect to find them, and where, if aspect, convenience, or appearance had been considered, they would have been placed. The first consideration in the selection of a site is

Soil.—In some respects this is a question subservient to that of situation, for part of the soil can be brought from the neighbouring fields, as I have known it done, rather than sacrifice a site otherwise suitable. It is found that most kitchen garden crops and fruit trees thrive in soils of widely different character. I have known a garden in which most plants flourished well, except in very dry seasons, where the soil consisted almost of pure red sand on a sandstone formation. Indeed, it was found to be so sandy at a spade's depth, that, to get a tilth of sufficient substance, most of the soil had to be carted from the fields around where the garden was made. A good sandy loam is best for general purposes, and very light or very heavy clayey soils should be avoided. Otherwise no soil is bad that yields fair pasture, provided it is deep enough; but, as a rule, it will be not only desirable, but necessary, to trench the ground over to a depth of 2½ feet, or 2 feet at least, adding to it at the same time such materials in the shape of leaf mould, manure, turf scrapings, clay, general vegetable refuse, lime, &c., as may be found needful to improve the staple, and the improving process may be continued annually by trenching and re-turning as much ground as circumstances will permit.

Situation.—In choosing a situation two important considerations are shelter and water. Shelter is of the utmost importance, for cutting winds have, if anything, a worse effect upon growing crops than spring frosts. The most injurious prevailing winds which we experience in this country are from the north, north-east, and east; the western hurricanes are more destructive by their force than otherwise. At all these points, therefore, but particularly the former, shelter should be provided, either by taking advantage of rising ground or plantations. If these do not already exist, then plantations should be made of those trees which are found to grow fastest and most luxuriantly in the district; but, in any case, sheltering objects should be far enough removed to prevent injury by their shade. Low situations, though generally affording the best means of shelter, and also the deepest and richest soil, should not always be chosen, for various good reasons. The site should be at a moderate altitude, where, if the natural soil is not so good, the sub-soil is generally drier, and the facilities for drainage much greater. The ground should be level, or slope gently to the south. Steep slopes should be avoided, even if it is necessary to make the garden at a considerable distance from the mansion; for, in addition to the extra difficulty of working such ground, the soil is very apt to be washed with heavy rains, causing much loss and inconvenience.

Water.—As regards water, the supply cannot be too close at hand, and hardly too plentiful, in a kitchen garden; at the same time proximity to a lake is far from desirable, on account of late frosts. Some notable mistakes have been made in this respect, and late and early frosts work annual havoc with vegetable crops and fruit trees; indeed, French Beans, early Potatoes, and similar plants are secured only by the most elaborate protective measures. From whatever source the water is supplied, it has, in most cases, to be distributed throughout the garden by means of pipes, and, whether for hose and hydrants, or taps, it should be readily accessible at numerous points to ensure its plentiful application when required, and save labour in carrying. When the supply comes from a natural reservoir (assuming that hose and hydrants are not available), open tanks are not so needful; but when the water is pumped, or from a bore-hole, and consequently always considerably colder than the soil,

tanks are then a necessity, and, by being always kept full, the water will generally be warm enough for all purposes.

Extent and Plan.—The extent of ground to be devoted strictly to vegetable and fruit growing must, of course, depend upon the demand. Nothing less than 1 acre will suffice for any house above the pretensions of a cottage. The number of people that this area is calculated to supply with vegetables or fruit in season is variously estimated at from twelve to eighteen, according to the climate and soil, &c. Probably fourteen is as many as could be supplied in a moderate way, and I would not put the number so high even as this where the kitchen garden is expected to produce more than an early and second early crop of Potatoes. Another consideration is the means allowed to work the garden—a question affecting the production quite as much as the extent. It is much better to utilise 1 acre thoroughly than to have 2 acres only half-cropped and ill-managed; but in estimating the area to be enclosed by walls it should also be remembered that it costs less, proportionately, to wall in 2 or 3 acres than it does 1 acre, while there is an extended wall surface for fruit trees, which is of some consequence in a cold climate; besides, if the ground is not all required for vegetable crops at times, it can be employed some other way. As to plan, the simpler it is the better. A parallelogram running east and west, that the greatest extent of wall surface and borders may have a south aspect, is the usual and most approved form. The walls should never be less than 12 feet in height. The north wall might be made considerably higher than this with advantage—perhaps 16 or 18 feet—the east and west walls descending by ramps from each corner towards the south. This would not only increase the sheltering power of the walls, but would afford more room upon them for training fruit trees, a 12-foot wall being too low for many kinds of fan-trained trees. When the area enclosed does not exceed more than 3 or 4 acres, an intersecting or middle wall is not to be recommended, as it necessitates a further sub-division of the ground and more walks, which reduces the cropping space; but, in a 6 or 8 acre garden, such a wall is an advantage for the shelter it affords from cold winds, the boundary walls under such circumstances exerting hardly any influence in the central portions of the garden, over which the blast sweeps as over an open field. Within the walls the ground need only be divided into four quarters by broad intersecting walks passing through its centre each way, and communicating with the side walks, which should run entirely round the square, having a 12 or 14 feet border between it and the walls for the fruit trees. In very large gardens the quarters may be again sub-divided by narrower walks, for convenience in distributing manure and clearing the ground of crops, &c.; but no purpose is served by departing from the square form in making the plots. It is usual to have the range of fruit and hot-houses inside the walls, which is an excellent arrangement. In old gardens these houses generally abut at once upon the vegetable quarters; but, as they generally afford a pleasant and interesting promenade now-a-days, the external surroundings may be a little more in keeping. The best arrangement I have seen in this respect was the placing of the houses on a level site at the top or north side of the garden, with a broad walk in front the whole length of the range, and between the walk and the quarters a strip of Grass with a few low shrubs in flower beds here and there, and, beyond, espalier fruit trees, as a screen to hide the rougher vegetable crops behind. It is not the place here to enter into details connected with the laying out of the ground, and I shall conclude with a few remarks on the drainage. The sub-soil in some districts is so porous, and carries off all superfluous water so readily, that draining is perfectly needless. In deep or heavy soils, resting on retentive bottoms, draining is, however, of the utmost importance; for little or no success can be expected in the culture of the majority of vegetables, and certainly nothing can be done with fruit-trees when the surplus rainfall does not pass quickly and freely away. The drains should be about 20 feet asunder, and 3 feet to 4 feet deep—deep enough, at all events, to prevent their being disturbed at any time in gardening operations, such as tree-lifting, planting, or trenching, &c.; 2-inch tiles are wide enough, unless in unusually wet districts; and the drains should have sufficient fall to the main drain, which should be calculated to carry off readily as much water as the whole series of drains are likely to pour into it at one time. C.

Root Grub.—I have lately noticed in your columns remarks relative to this insect, known as grub, and the means of protecting plants from its ravages. As my garden is greatly infested with insects I avail myself of the present opportunity to send you some grubs which give me infinite trouble and vexation, and which I imagine are the pests alluded to at page 400, in your issue of the 15th ult. As mentioned there, the plant suddenly begins to flag,

and, when pulled, comes away from the ground with ease without the root. I have used powdered lime, but with no good effect. I shall, however, try it mixed with soot. I am more particularly troubled with it in a north border, which, being under the shelter of a brick wall, is shaded from the sun, but I find that it is spreading all over the garden, and being only an amateur, I am somewhat disheartened with my want of success. In the vegetable garden, these grubs attack with great energy Strawberry plants, eating off the leaves and bloom, and my Spinach has also suffered severely from them. I should feel obliged, therefore, if you could inform me of any way of destroying them, as they seem most difficult to kill. I have placed some in a vessel containing tolerably strong soda and water, and they have been alive 36 hours afterwards; strong salt-water kills them after some hours, but this could not be used in the garden where plants are growing. I have been recommended to use chloride of lime and water, but should be glad of some information concerning such a mixture before using it. I am also much annoyed with respect to worms and centipedes eating out the hearts of my bulbous roots, and have lost my Japan Lilies through this cause.—**BETA.** [The grubs sent are what are called "leather jackets," from the toughness of their coats. They are the larvæ of the Daddy-long-legs fly (*Tipula oleracea* or *T. maculosa*), and do an infinite amount of damage in their young stage to the roots of many plants. Curtis describes the various devices he tried to get rid of them, and, among others, are those which have occurred to your correspondent, brine, soda, lime water, &c., but he ends by saying that the only remedy he has practised with success has been searching for them round sickly plants, and digging up all that have been just eaten off by them.—A. M.]

The Ravages of the Potato Beetle.—"R. E. P." writes to the "Times":—"I own, in Chester co., Pennsylvania, a small farm of about 34 acres. The mansion-house, to which 7 acres are attached, I used as a residence during the summer months, the remainder was rented to a neighbouring farmer. Last spring he planted his Potatoes in a field adjoining my vegetable garden, 2 acres of which were also planted with Potatoes. In the month of August the farmer's Potatoes were attacked by the beetle. Lime in powder was sprinkled over the plants, but to no purpose. The tubers were injured to that extent that it did not repay the trouble of taking them out of the ground. My plants escaped until September, when I perceived a few beetles on the haulm, which soon became a host, and the plants above ground were quickly destroyed. The tubers were but slightly affected, as they had almost attained their growth before the haulm was attacked. Alongside of the Potato patch a row of purple Egg plants were under cultivation; these were attacked, and both fruit and leaves were destroyed. The beetles were numberless, and could be taken up by handfuls. After this they came up into the house, and were found creeping over the verandah and into the sitting-rooms and chambers. It is not astonishing that the Mayor of St. Louis should have replied as he did to his correspondent. Prior to my experience in August last, I might have written as he has done. It is certainly a pest greatly to be dreaded, and although I perceived that some of your correspondents think that the climate of Great Britain will not agree with them, I hope that the experiment may not be tried.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Another Remedy for the Potato Disease.—Mr. William Jenkins, of the Willows, Abergavenny, writes to us stating that he has found that if a mixture of two parts of cotton-seed oil and one part of kerosene be applied to Potatoes before planting, the result will be a crop free from disease.

Fern-leaved Parsley.—We have sent you specimens of this Parsley, a kind picked up by our traveller in the United States a year or two ago. We consider it distinct and beautiful, and we intend offering it to the public next season.—JAMES CARTER, DUNNETT, & BEALE. [A remarkable variety cut into extremely fine segments.]

Snowflake Potato.—I purchased last spring 1 lb. (three tubers) of this new American Potato, and I cut them into twenty-four single eyes or sets, which were duly planted after giving time for the wounds to dry. Twenty-three are up and growing vigorously, and I am pleased with their appearance. The tubers are handsome, and the flesh white and delicate.—E. HODDAY, Ramsey Abbey.

Forcing Early Peas in Pots.—I have a quantity of early Peas in pots fit for gathering. They consist of the dwarf varieties *Multum in Parvo* and *Blue Peter*, two kinds which I can highly recommend for productiveness, and their pods are large for those of early Peas, while the Peas themselves are of excellent flavour. They have been grown in pits without much forcing, a little heat having only been put into the pipes in January and February to keep frost out. In the same pits I have tried *William the First*, but it is rather too tall for pot culture, although one of the very best early Peas grown in borders. I had my old favourite dwarf Pea, *Little Gem*, ready for gathering in the beginning of May, but I mean now to discard it in another year for growing in pots, as *Multum in Parvo* and *Blue Peter* produce larger pods and are more prolific.—WILLIAM TILLERY, Welbeck.

THE HOUSEHOLD.

COOKING SPINACH.

THIS excellent vegetable forms a good accompaniment to meat when plainly boiled in plenty of water, with all the moisture carefully pressed out of it; it should then be chopped small, put into a clean saucepan with a slice of fresh butter, and stirred until it is well mixed and very hot; it should then be placed smoothly in a dish, marked in dice, and served.

Purée of Spinach.—Boil it until quite tender, chop it, and rub it through a sieve with great care, put it into a saucepan with a small lump of butter and pepper and salt; stir this mixture well, taking care to preserve the green colour, and serve it hot. A dish of mutton or veal cutlets, or fried pieces of chicken, may be arranged like a crown on a dish with this purée in the middle, or there may be poached eggs or little rissoles placed upon the purée. Any of these form a pretty luncheon or supper dish.

Mould of Spinach.—Boil the Spinach, and, after it has been squeezed and chopped, stir it over a moderate fire until it is very dry; moisten it with as much thick rich gravy as will flavour it well, and turn it over and stew it fast until it is again dry; then press it into a hot mould of handsome form, turn it into a dish, and serve it quickly; 2 or 3 ounces of fresh butter may be used as a substitute for gravy. A perforated tin shape is the best for moulding Spinach, but one of earthenware, slightly buttered, answers perfectly well.

Spinach à la Française.—When boiled and chopped, put the Spinach into a pan with a tablespoonful of pounded sugar, a little grated nutmeg, 6 ounces of fresh butter, and a tablespoonful of flour; when this mixture has been stirred over the fire for some time remove it, and add a tablespoonful of thick cream; dish it, decorating it with fried croutons—these are small pieces of bread, cut out with a pastry cutter, and delicately fried in butter. Leaves of light pastry (baked) may be used instead.

Asparagus.

The superiority of English over French Asparagus is now pretty generally admitted. The French is very much blanched, and the stalk being consequently hard and tough, a great deal of it is wasted.* This is not the case with English Asparagus, most of which when well grown can be eaten. The variety which grows wild in some parts of the Continent, particularly in the Rhine country is good, though, of course, far inferior in size and quality to that grown in gardens. Asparagus is excellent, either as an accompaniment to meat or eaten alone, when plainly boiled in well-salted water (the addition of a bunch of Mint improves the flavour), and served on a toast, with good melted butter. French cooks add two tablespoonfuls of vinegar to the boiling water before the Asparagus is put in, in order to preserve its green colour. The time of boiling varies from ten minutes to half-an-hour, according to the age of the vegetable.

Asparagus Soup.—Take 1 quart of good beef stock, which has previously been well flavoured with Carrots, Onions, Parsley, and Thyme, add to it, a few minutes before serving, a small bundle of Asparagus (say one dozen heads), cut into pieces about 1 inch in length, and previously boiled, with a tablespoonful of purée of Spinach (made as directed in the receipt), a lump of sugar, a little Celery salt, and a very small piece of butter. A teaspoonful of chopped Parsley is considered by some people an improvement. Boil all these together for four or five minutes, taking care not to break the Asparagus. Serve the soup with fried bread in another dish.

Asparagus with salad mixture.—When boiled, throw it into a good quantity of cold water, mixed with four tablespoonfuls of vinegar. Let it become cold, and it will be green and firm. Dish it, and serve in a tureen, with a sauce prepared with salt, pepper, two tablespoonfuls of vinegar to five of olive oil. This is a favourite mode of dressing Asparagus on the Continent. French vinegar and the purest oil should always be used.

Asperges en Petits Pois.—This is a convenient mode when too small to make a good appearance plainly boiled; cut the points so far only as they are perfectly tender, in bits of equal size, the third of an inch long, boil them in well-salted water for ten minutes; if they are then tender, take them out, drain them, and spread them on a clean cloth; when dry, put them into a saucepan with a good slice of butter which has been previously dissolved, stew them gently for eight or ten minutes, dredge in a small teaspoonful of flour and nearly that quantity of pounded sugar, then pour in enough boiling water to just cover the Asparagus, and boil it rapidly until but little

* No waste need occur if the heads are all cut as nearly as possible to one length, tied in a compact bundle, and placed erect in the water, leaving about an inch of the tops out of it. In this way the tips of the shoots of even the largest Asparagus may be perfectly cooked, and the lower parts made to a large extent soft and edible.

liquid remains; stir in the beaten yolks of two eggs, heap the Asparagus high on a dish and serve very hot. The sauce should adhere to the vegetable as in green Peas à la Française. N.

GREENHOUSE PARASITES.

MANY who possess conservatories and greenhouses are wholly unacquainted with the various kinds of injurious insects that dwell in them, more especially those which feed on the life-juices of plants. Let me therefore give a brief description of these parasites.

Red Spider (*Acarus tellarius*), x 30.

I shall not, however, allude to the Aphides, the most mischievous tribe of all, as with these most of us are acquainted. The next greatest pest is the Thrips adonidum, which in the summer season abounds on every outdoor flower; as, for instance, the blossom of the Bind-weed, Dandelion, Rose, &c. This insect is minute, its colour being

Mealy Bug, x 20.

generally black or rusty; the abdomen is long and pointed, and its wings are of a dirty white; the antennæ and legs are yellowish, the extremity of the former being black. The larva and pupa are of a pale yellow, and very unsightly to behold, especially when seen under the microscope. These, as well as the mature insect, are found on

Full-grown Thrips, x 25.

the underside of the leaves they prey on, having pierced which, they extract the juice, depositing it in black spots over the leaf. This being of a glutinous nature, fills the pores, and afterwards the leaf turns a pale yellow or a sickly green, and falls off. In March the full-grown insects are found collected together, and as the warm

sun of spring comes forth, they depart abroad to raise a household for themselves. Another species, called *T. ochraceus*, feeds on fruit, and does great damage to it by piercing the stalks, and causing the fruit to fall off before it is ripe. In appearance it is similar to that just mentioned, but it is more hairy. The next destroyer appears under the classical name of Coccus, or scale insect. Those generally found fixed on the stem and leaves of the plant are females. They are shield-like in shape, being convex above and flat or concave below; have six small legs; and, as the insect increases in age, these grow into their bodies. On the underside of the insect is a sucker, with which it pierces the cuticle of the plant, so as to obtain the desired food. Soon after the female lays her eggs she dies, and her body becomes covered with a long white woolly substance, that guards her eggs during their incubation. The Coccoi are of various colours, the darkest being generally the fullest-grown: the males are active, and are very small. There are many species of the same insect, known as *C. Vitis*, *C. Testudo*, *C. Hesperidum*, &c. They should be exterminated as soon as they appear, for if allowed to get ahead, there will be great difficulty in effecting this afterwards, as they increase at a prodigious rate. Another pest is the Mealy Bug. This is not unlike the common Wood-louse, but is of a reddish colour, and covered with a white mealy powder. The male is slender, shaped somewhat like

Larva of Thrips, x 25.

Upper side of Scale Insect, x 25.

Under side of ditto, x 25.

a gnat, has a pair of broad wings, and two brush-like appendages behind. The last member of the craft to which I shall allude is *Acarus tellarius*, better known as the red spider; in fact, although last named, it is not least in its power of destruction, and the difficulty of eradication; being excessively small it is not easily seen unless by keen eyes. It is generally of a bright brick-red, yellow, or brown colour; on each side of its back is a small black spot: this only is seen when magnified. Its shape is similar to the generality of the Acari tribe. It is found on the undersides of the leaves of the plants infected; while there it sucks the juices out of them, and by the web it spins from vein to vein, destroys the power of healthy inhalation of the life-giving gas; the leaves then turn pale-coloured, and fall off. This in many instances destroys the vitality of the plant. One thing is very remarkable, and that is, how Nature has provided for the safety of these insects by giving them the instinct to hide from general view, on the undersides of the leaves, telling them, as it were, "that they are thieves, and must work in the dark." There are many modes of destroying these enemies of vegetable life, says "Science-Gossip," from which these remarks are taken, the principal being fumigation, syringing, and dusting the stems and leaves with compounds of a powerful nature.

The Hardest Gum Tree.—According to experiments tried at Tours, *Eucalyptus rostrata* would appear to be the hardest species. Our Californian readers could probably add something to our knowledge in this respect, as the Gum trees have been very extensively planted in that country, and many kinds of them.

Value of the Acacia Wood.—The Locust tree (*Acacia*) is used in large quantities for the wheel-spokes of the best carriages made in France. This tree, the cultivation of which was so strongly recommended a generation ago, has been in great disfavour with growers. As the steadily rising prices of carriage-work render it more profitable, it begins to be more in favour. Its extraordinary lasting qualities when used as posts, either in earth or water, are well known.—E.

Cedrus Deodara in Ireland.—Perhaps the finest avenue of Deodars in Ireland (says the "Gardeners' Record") exists at Charleville, the seat of Viscount Monck. The specimens, which are planted on either side of a walk nearly 500 feet in length in the pleasure grounds, are very large, even in girth, and in the most perfect health. Many of them vary in character to a remarkable degree—one specimen in particular being most distinct in habit and appearance. The side branches of this particular tree shoot out more horizontally than those of its neighbours, and the tips of the side shoots droop more perpendicularly than is usually the case with this tree. As seen now, with its new, pale yellowish-green growth and graceful habit, few Conifers, if any, can match it.

TREES AND SHRUBS.

ADVANTAGES OF PLANTING IN GROUPS.

By WILLIAM GORRIE.

WERE the question merely, whether grouping or mixed planting is most productive of landscape effect, it might be conceded that the unanimous verdict would be in favour of judicious grouping—and that also on landed properties of all sizes, from the 2 or 3 acre villa, where groups are necessarily restricted to a few specimens, upwards through increasing sizes of country estates, to the most extensive and variously surfaced demesnes, where they may form masses of tens, twenties, or even hundreds of acres of the same or closely allied kinds. But were grouping only to be deemed admissible on condition of its being equally profitable with mixed or promiscuous planting, I fear that its most strenuous advocates would fail in its defence; more especially were it required that its landscape effects should be maintained unimpaired by other kinds of nurses from the time that the young trees attain to sufficient size for concealing the natural herbage of the ground surface. For, in the first place, there is the additional cost of the young plants; and, secondly, the thinnings will not yield nearly the money returns that would be derived from Larch, Firs, and other cheap and fast growing nurses. I will return to this subject after making a few remarks on the grouping of trees for landscape effect, under the following heads, viz.—1. Soil and situation. 2. Forms and sizes of groups. 3. Grouping with the same and allied kinds. 4. Grouping with different kinds. 5. Grouping with respect to size, form, and colour of leafage. 6. Park clumps, belts, groups, and solitary trees. 7. Avenues. 8. Fences.

1. Soil and Situation.—The choice of soils and situations best suited for the healthy development of the different kinds of trees is even more important in ornamental than in economic planting, and as, in the former, the number of sorts dealt with is much greater than in the latter, a more widely extended knowledge of arboricultural botany is needed than is usually aspired to by merely practical foresters. Farther, in ornamental planting, a knowledge of the wind-resisting powers of the different kinds of trees is specially needful, in order to arrange them so that the stronger may shelter the weaker, and prevent that one-sided appearance that, although prized by artists in depicting wind-beaten scenery, is looked upon by tree-admirers with feelings of unpleasantness.

2. Forms and Sizes of Groups.—Premising that in group planting the operator should have a clear perception of the appearances that all the kinds of plants operated with will present at the successive stages of their after-growth, the forms of groups should be irregular, and without hard or harsh outlines, as exemplified on a large scale by the few native forests that are still left in our country, where, from masses of the Scotch Fir on the lower flats and hill sides, flake-like portions run up irregularly into the more or less sheltered hollows and ravines, skirted and interspersed, where the soil is wet, with groups of Birch, Alder, and Willows; occasionally underwooded on drier and rocky parts by patches of the Hazel, Mountain Ash, Bird Cherry, Holly, and Juniper. It is in planting large extents of hills and mountain slopes that grouping or massing can be carried out to the fullest and most effective extent. And although this may be done successfully with the kinds of trees in ordinary cultivation, it can be far better accomplished by employing a much greater diversity of sorts; commencing near the sea-level with Chestnuts, the true Planes, Walnuts, and other natives of southern Europe, or of similar climates, associated with Poplars and Willows by the water-courses, and succeeded in ascending progression by Limes, Oaks, Cedars, Elms, Maples, Ash, Beeches, Silver Firs, Spruces, many of the true Pines, and others, the hardier of which fringe extensive masses of the more remunerative Larch and Scotch Fir, till succeeded in turn by the Cembran and Mountain Pines, Birch, upland Willows, and other representatives of the higher regions of tree life. Grouping on a large scale may also be done with good effect in low country, flat-lying plantations that are much overlooked from elevated places, as residences, public roads, railways, &c. But with such plantations it is generally more expedient to restrict the grouping to near and at their outer margins. In plantations on such an extensive scale as here indicated, the most remunerative kinds of trees should of course form the larger masses; but no group should be so small as to be ineffective, or indistinctly noticeable in the general landscape, when viewed from important, although somewhat distant, points of observation. These remarks, with reasonable modifications, are also applicable to plantations of diminishing extent, down to the villa grounds of a few acres; where the outside appearances should not be forgotten, although the views from the house windows and internal walks may be deemed of more paramount importance. But even here grouping is decidedly pre-

ferable to mixed planting. Where, however, the space to be operated upon is very limited, it is seldom advisable to plant more than one tree or shrub of the same sort, and that should generally be associated or grouped with its marked varieties or kindred species.

3. Grouping with the same and allied kinds.—By far the most generally commendable mode of group planting is that of associating species with their varieties, and others belonging to the same or allied genera. Here, however, the question of economy would come in with hindering, if not prohibitory effect, were it necessary that all the kinds should be the same or nearly the same in number. But this is by no means the case; for the kindred kinds deemed ultimately to be most remunerative may predominate so far as to produce the desired landscape effect, the others being introduced as side groups of greater or less size, proportionate to the original cost of plants, and their ultimate commercial value. All that are intended to be permanent specimens should be allowed plenty of room for their full development; and they should be arranged so that their decreasing heights will show off the taller kinds behind, and bring down the general outline to connect agreeably with the adjoining ground surface. Where allied dwarf grouping kinds will thrive as underwood, they are the most suitable to plant as such, and next to them shrubs with somewhat similar foliage; for nowhere should the under growth contrast harshly or unpleasingly with the general mass when viewed from the outside, unless when only of such low heights as to associate with the Grass and other natural ground herbage. As an example of regular and hard outline grouping to be avoided, a plantation of fully fifty years standing may be instanced on the steep rugged slopes of Kinnoull Hill, near Perth, where the different kinds were originally grouped in straight-sided, square, and parallelogram-like fashion, except where some of the outlines are broken into by the bases of the magnificent precipices which form the preponderating features of the hill. Thinning out, and the irregular spreading tops of the reserved trees, have tended in some measure to tone down the rigid straightness of outline which the groups originally presented; but they still and will remain as blots in landscape arboriculture. Another, although less objectionable example, in which the outlines are more irregular, but not less abrupt and harshly defined, is observable from the decks of Clyde steamers in passing between Roseneath and Kilcraggan—the age of the trees appearing to be between twelve and fifteen years.

4. Grouping with different kinds.—Trees widely different in their affinities, but having a resemblance to one another in the size and forms of their leaves, may be associated in groups. Mixture of kinds, however, is most commendable when they possess some other marked characteristic in common, such as colour of foliage, bark, and flourish, habit of growth, or form, &c. Thus, when depth or darkness of colour in leafage is desired, fit associates exist in the purple Beeches, Oaks, Elms, Hazel, Barberry, &c. Where light colours are wanted, they are at command in the Corstorphine Plane, the Golden Oak (*Quercus pedunculata concordia*), Golden Ash, Birch, Alder, and Elder, as well as in the gold and silver-shaded Yews, Moonlight Holly, Spruces, and smaller Coniferæ; as also among the naturally silvery-foliaged trees, such as the Abele Poplar, the Huntingdon, and some other Willows; the Whitebeam or Service tree, Sea Buckthorn, &c.; while among strictly variegated trees and shrubs there exists a wide field to select from. The autumnal colours and tints of fading foliage deserve marked attention at the hands of planters for ornamental effect. And whether the rich scarlets and purples of our native Geans and of some American Oaks, the golden-yellow of the Norway Maple, or whatever colours are wanted in plants that have been grown from seed, it is a wise precaution to select them in the nursery, when the colours are most marked, as the fading leafage of plants raised from seed is generally much varied, although these be of the same species or kind. Colour in bark is most appreciable when branches are denuded of their foliage; and small or moderately-sized groups, having distinct colours, tend to break up or relieve that dull monotony which prevails in deciduous woodland scenery throughout the winter and early spring. The following may be instanced:—With white or light coloured bark—the common and several other kinds of Birch, Constantinople Hazel, Snake-barked Maple, the Cane or white Welsh Willow (*Salix decipiens*), *Cratægus punctata*, and some other Hawthorns, &c. With yellow or orange-coloured bark—the yellow-barked small and large-leaved Limes, Golden Ash, Golden and Copper Willows, &c. And with reddish, dark, or blackish bark—the red twigged or coral Lime; *Salix acutifolia*, *S. Daphnoides*, *S. purpurea*, *S. nigra*, and some other Willows; *Cratægus M'Nabiana*, and several other Hawthorns; the red Dogwoods, &c. With regard to flourish—although the Horse Chestnut and the Gean are the only full or large-sized forest trees that produce showy blossoms, there are of smaller trees the Pavias, and other allies of the former; while, belonging to the same natural order as the latter, there are others of

the Cherry tribe, Hawthorns, Services, Mountain Ashes, Mespiluses, Almonds, and the wild form of the Apple, Pear, and Plum. In other families, there are the Scotch and English Laburnums, Robinias, Lilacs, Elders, &c., which, together with Rhododendrons, Azaleas, Weigelas, and other flowering shrubs too numerous to mention, are admirably adapted, when grouped according to their colours, for decorating the margin as well as the interior of our woodlands. And on prominent rocky snabs, natural sites for the Rowan, the Gean, and Sloe Thorn, the snowy whiteness of the last two displayed before the earliest leafage of spring, is ever the admiration of all beholders. Of distinct habited trees, drooping or weeping kinds, which only attain to little above their original height, are very serviceable for shutting out lower and near-at-hand unsightly objects, without impeding the views of more distant and important scenery. In such a case, weepers being comparatively few, a judicious mixture of kinds becomes necessary in order to obviate disagreeable monotony and uniformity. This suggests a procedure that is too generally neglected in opening up views that have become interrupted or shut out by the overgrowth of injudiciously planted trees, viz., that of grafting some of these with weepers at requisite heights, particularly Ashes and Elms, which are the most easily operated upon; and the more general adoption of this practice would be the means of retaining many a fine stem or bole, where their presence is ornamental as well as needful. Among upright, pyramidal, and conical-formed trees, we have the Lombardy Poplar as the most important, from the great height to which it attains, as well as from the remarkably fastigate upright habit of its growth, characteristics which render it highly suitable for certain localities, but most incongruous in others. Thus, when neither too thickly nor over widely grouped at the ends of a bridge, viaduct, or high-level topped embankment, those horizontal lines are, as it were, balanced and supported by the perpendicular lines of the Poplars, and the latter have a singularly important landscape effect when seen rising from among ordinary plantations over these horizontal surfaces, as well as over flat-topped ranges of buildings, while, among or rising behind groups of round-headed trees, their occasional presence has a very pleasing effect. On higher, drier, and more exposed grounds, some of the taller-growing conical-topped Conifers, such as the Silver Fir, are productive of similar results; but great care is requisite not to introduce either these or the Lombardy Poplars over abundantly. In pleasure-grounds, a lower class of fastigate trees, as well as of shrubs, may be introduced with equally effective results, such as the different upright-growing Elms, fastigate Oaks, Hawthorns, Thorn Acacia, Alders, Yews, Junipers, Cypress, &c.; but neither should they be over abundantly planted.

5. Grouping with respect to size, colour, and form of Leafage.—In planting, as in painting, light and dark colours, as well as size impart apparent nearness or distance when the trees are equally removed from the observer, and this is still more obvious when the leafage is alike or nearly so in form. For example, if a Corstorphine, a common, and a Jersey Plum or Sycamore are thus equi-distant, the light colour of the first will make it seem nearer than the second, while the darker colour of the last will make it appear as if still further off. In like manner, with the common Sycamore, the Sugar Maple, and the English Maple, the diminishing size of the trees, as well as of their foliage, would seemingly place the first in advance of the second, while the last, from its much smaller as well as darker green foliage, would appear as if considerably beyond. Again, with very dark colours, such as the Purple Beech, Purple Elm, and the like, if these are planted equi-distant with common Beech and Elm, the purple-foliaged trees would appear much further off in proportion to the depth of their colouring; and these effects are still more marked when such very dark-foliaged plants occupy situations that are shaded from the sun at the time of observation, as on the north or east sides of plantations. Deciduous trees retain the aforesaid appearance of nearness and distance according to the size of their foliage, even when it has fallen, from its being a general rule that the strength or thickness, as well as the number or quantity of the young shoots or branchlets, is proportionate to the size of the leaves. This is exemplified in our largest-leaved trees, the Horse Chestnut and Common Plane, with their few and thick shoots, contrasted with the Birch, which is at once the smallest leaved and most slenderly as well as closely twigged of ordinary forest trees. One of the seemingly most difficult problems that the landscape forester has to solve is that of making straight lines appear crooked, and stiff ones easy. This, however, is often a very necessary performance, as in the case of hedge-rows and other lines of trees, as well as in straight or stiff outlined belts and plantations. But it can be often successfully performed by attending to the preceding rules.

6. Park Belts, Clumps, Groups, and Solitary Trees.—In arboricultural decoration of most of the ornamental parks and

pleasure grounds that surround country mansions, there is too much unmeaning sameness and want of design. The outer belts, as well as the interior clumps, are usually planted with unseemly mixtures of overcrowded ordinary kinds of forest trees, rising abruptly to full height from their fence enclosures, without any attempt at rounding or sloping them down so as to associate harmoniously with the surrounding turf, by means of intervening ornamental trees of diminishing stature and shrubby underwood. Not unfrequently some convenient corner is set apart for Conifers or other fashionable novelties so near the mansion, that either it or they will have to be removed before they are half-grown. Or, if sufficiently remote from it, they are planted so close to one another, that, to prevent the whole becoming unsightly abortions, the axe will have to be freely applied for thinning ere they are half a century old. Others, it may be, are scattered about at more suitable distances; but, with such, a too common fate is injury or destruction from the drip, shade, or wind-falling of too near and much older neighbours. This last remark is not to be taken as recommending the removal of fine old park trees, that may have been favourites with their successive owners for centuries, but is, with the others, designed as an argument against planting choice young trees in such situations, when, in many instances, better accommodation might be had for grouping them in the belts and clumps before mentioned. Park belts and clumps are admirably adapted for grouping trees and underwood in the different manners before described; and detached clumps are specially suited for grouping the different families apart. Thus the Oak would form one of the largest and most perfect clump groups; comprising as that genus does not only round and spiry-headed trees of the largest sizes, but also many tall as well as dwarf evergreens, and a goodly assortment of low and intermediate-growing deciduous kinds, together with a wide diversity in the sizes of their leaves. Compare, for instance, those of the common Oak, which are by no means the smallest, with a leaf of *Quercus macrophylla*, such as that brought away by Mr. Baxter from Riccarton, which measured 17 by 7 inches. Clumps of such other families as are deficient in required characteristic particulars might have others of needful forms, colours, &c., tastefully associated with them, both as trees and underwood. Park groups of separately fenced trees should only be of select fine-growing kinds, and single trees still more particularly so; each group of the former generally consisting of allied varieties, species, or genera. And plants of Hawthorn, Briars, Sloe Thorn, Furze, &c., growing from at and near the base of some of these singly-fenced trees, produce a good effect by dispelling that sameness that their bare stems would otherwise present.

7. Avenues can scarcely be left without a passing notice when treating of group planting. They may either be straight or curved, and are generally associated with a roadway or a grassy ride; and they may either be composed of two lines, all of one kind of tree; four lines of two kinds or tribes of trees, or what may be termed the arboretum avenue, in either two or four rows of distinct sorts, grouped or brought together in families. The first, when intended to form a close gothic arch-like covering, should be planted near to one another in line, and they may be as near to the roadway on each side as half its width. The second or double avenue should generally have the rows next to the roadway or drive of one kind, and the other two rows of a different kind; but full space should be allowed for the after development of every tree, from the ground upwards, without touching one another, encroaching upon the roadway, or concealing from it the trees in the back rows. A very usual and generally commendable practice is to have two corresponding rows deciduous and the other two evergreen trees. The third, or arboretum avenue, is better in four than in two rows, where sufficient space can be devoted to them, as they admit of the dwarf kinds being kept in front and the taller ones behind. And in both the second and third kinds of avenues the back lines may be associated with groups of underwood and shrubbery where adjoined by plantations, and where concealment of or from the outside is intended. This arrangement is peculiarly suitable for the arboretum avenue, as affording scope for a collection of underwood or small trees and shrubs, as well as of the larger trees. In selecting the kinds of trees for forming the first two described avenues, it is most essential to avoid such as are capricious in their adaptation to any diversity of soils or exposures that may present themselves, so that the greatest possible uniformity of healthy growth may be secured throughout the whole length. And they should, by continuous yet almost imperceptible pinching and pruning, be kept in pleasingly symmetrical forms, so as to prevent the growth of double tops and disproportionately large side branches, that are unsightly in themselves, and become liable to wind breakage as they progress in size and age. In regard to the sites or situations of avenues, whether straight or curved, those are best where they do not cut up fine expanses of grassy greenery, or conceal distant interesting scenery—as by the outer edges of such expanses,

through or by the sides of woodlands, and outside of home parks, where approaches have to be carried through arable fields; for which last the second and third modes mentioned are specially adapted.

8. Fences.—With reference to plantation fences, it may be remarked that grouping for the purpose of breaking up stiff outlined belts and margins becomes far from effective when these are fenced by obtrusive stone dykes. When the outside of a plantation thus grouped is looked upon over an intervening knoll which conceals its fence dyke, the apparent distance or nearness that is thus imparted to its margin becomes in a great measure dispelled on advancing till the dyke become visible. Hedges, and more especially well-kept ones, are liable to similar objections, but in a less degree; and this may be still further lessened by suiting them to the trees and underwood behind, as by an entire or thickly mixed hedge of the purple-leaved Barberry, where, backed by purple Beech, Elm, Hazel, &c.; by Holly, Mahonia, evergreen Privet, &c., in front of broad-leaved evergreens; and by Whins, Junipers, &c., where backed by small-leaved evergreens, such as the Coniferae. Iron fences, except for shelter, are preferable to either of the preceding when sufficiently distant from the drip of high trees, to allow of a thick growth of underwood between. But a fence preferable to either, especially for ornamental park groups, clumps, and belts, can be cheaply formed where stones are abundant, by arranging those in irregular rockery-like outline, say 15 to 18 inches high in front, backed alternately by larger ones in four, six, or even more circumjacent informal layers or lines, with small spaces between, and only a little rise in the ground surface, where requisite, to supply soil for the free growth of thorny plants, such as the wild and double Scotch Roses, in front; Sweet and other Wild Briars, as well as a mixture of the more robust growing garden Roses, Furze, Barberry, Junipers, &c., next; then Hawthorns, Hollies, Sloe Thorn, and Sea Buckthorn, the last in dry, bare places, where the others will not grow; the whole being thickened by an undergrowth of Mahonias, Brambles, Ayrshire Roses, Honeysuckles, Ivy, and other rambling creepers, allowed to grow in natural wildness. This would form an impenetrable, as well as a highly picturesque barrier, against the inroads of both man and beast, besides being one of the best for game covers; and the interior might be fitly occupied by spineless underwood and shrubs, interspersed with strong free-growing herbaceous plants, a race far too much neglected in ornamental forestry. The well-known aversion that cattle and sheep have to passing over rough stony surfaces, even when by no means thickly interspersed with thorny vegetation, argues well in favour of this wild-fence notion; and, if fairly tried, it will doubtless be found cheap and effectual, as well as ornamental. As with ordinary hedges it would, of course, require temporary outside fencing.

Nurses.—As regards these, wherever the landscape effects of group planting are intended to be early and continuous, the nurses employed for sheltering the young permanent plants should be either the same or of the faster-growing kinds that assimilate with them in general appearance, for the obvious reasons, that they give the required shelter soonest, and they are the most remunerative as thinnings. For example, the Larch, as a nurse for the Larch; the Scotch Fir for itself and other true Pines; the common Sycamore for its own kind, as well as for others of the Acer family; the Turkey Oak for others of its genus; and the Ash, in addition to sheltering its own relations, will make a passable nurse for the Walnut and others having similarly divided leaves. As a nurse for the Silver Fir and the darker coloured Spruces, the Balm of Gilead or Balsam Fir is especially suitable, from its dying out generally at from 25 to 30 years of age, and thus obviating the tendency that too often exists among woodmen to spare trees after their presence becomes hurtful to their neighbours. When the early effects of group planting are not deemed paramount, the Larch will prove a profitable nurse, in situations not calculated for its long-enduring healthy existence. In order to get the greatest number and value of thinnings from a given space, pruning, by shortening or cutting in the side branches of the nurses, so as to prevent them interfering injuriously with the reserves and with one another, as well as for stimulating their upright growth, is a treatment deserving of notice, which was recommended so far back as 1825 by W. Billington, superintendent of planting in the Forest of Dean; and in 1841 by the late Gavin Cree, of Biggar, whose somewhat different mode has since been very successfully practised on the estate of Sir John M. Nasmyth, in Peeblesshire, as well as on that of the Earl of Stair, in Midlothian, and elsewhere.

Applying some of the preceding remarks to near-at-hand examples of avenue treatment, you will, on visiting Sir Walter Scott's monument, and the renowned Edinburgh Meadows, have opportunities of estimating the arboricultural taste and skill of our city rulers. At the former, you will see avenue trees selected with the utmost disregard to their adaptation for the soil and situation; the kind

being the common or Wych Elm—one of the most capricious of ordinary forest trees—each with a stem of a few feet, surmounted by a besom-like head of numerous contending branches, as if (should they ever attain to sufficient sizes) for the easy ascent and comfortable accommodation of city roughs when viewing passing processions. At the latter, where, according to R. Maxwell, of Arkland, Mr. Hope, of Rankeillor, commencing about 1722, "raised beautiful hedges and trees, made rich meadows and pleasant walks, where gentlemen and ladies resorted;" and which, in "Campbell's Journey through North Britain," 1810, are described as "a Mall lamentably unlike St. James's, being shamefully neglected avenues, where there was no longer pleasure in wandering among broken-down hedge-rows and blasted trees;" a description highly applicable to their management up to the present time, as you will see by their general appearance, and especially by that of the murderously mutilated, ill grown, distorted, unsightly avenue of trees which cuts in two the lengthy expanse of grassy meadow, and regarding which so much has of late been said and written.—"Transactions of the Scottish Arboricultural Society."

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE EXHIBITION.

MAY 29TH.

THIS was, on the whole, an interesting exhibition, pot Roses, stove and greenhouse plants, Azaleas, Heaths, and new and rare plants being well represented. Orchids were also shown in excellent condition, and there were some fine collections of plants staged for effect, as well as small Palms, Ferns, and other graceful plants in pots, suitable for dinner-table decoration.

Stove and Greenhouse Plants.—Of these, excellent specimens came from Messrs. Jackson, of Kingston, who had *Boronia pinnata*, well flowered; *Dracophyllum gracile*, 4 feet in diameter, and a mass of snowy blossoms; *Azalea petuniæflora*, 4 or 5 feet in height, and well bloomed; the yellow-flowered deep green-leaved *Erica depressa*; *Clerodendron Balfouri*, in excellent condition; *Hedera fuchsoides*; *Phenocoma proliferum*, and the soft rosy-flowered *Pimelea Hendersoni*. These varied from 3 to 5 feet in diameter, and were all well grown and flowered. Mr. B. S. Williams had good plants of *Allamanda grandiflora*, *Erica tricolor Wilsoni*, *Clerodendron Balfouri*, and a noble plant of *Hedera tulipiferum*, profusely bloomed, and fully 5 feet in diameter. In the same group were excellent specimens of the scarlet-spathed *Anthurium*, and *Bougainvillea glabra*—the last a striking plant, when in good condition, as this was. In the amateur's class, Mr. Ward, gardener to F. Wilkins, Esq., of Leyton, had well-grown specimens of the *Anthurium Scherzerianum*, *Erica Cavendishii*, *Dracophyllum gracile*, *Ixoraamboynensis*, and *Hedera tulipiferum*, also a well-flowered *Aphelexis macrantha purpurea*, and one or two other plants. From Mr. Chapman and Mr. Peed likewise came good collections of well managed plants. Among those from Mr. Chapman were *Ixora Prince of Orange*, a fine kind, bearing great trusses of orange blossoms, the foliage being as good as that of *coccinea*. *Aphelexis macrantha rosea*, well flowered. Mr. Peed had two well-grown *Francisceas*, namely, *F. calycina* and *F. confertiflora*, both profusely bloomed, and a well-furnished plant of the crimson and white-flowered *Clerodendron Balfouri*. The same group also contained *Eriostemon scabrum* and *E. buxifolium*, and a fine plant of the orange-yellow *Azalea sinensis*. Conspicuous amongst foliage plants, which were well represented, were some magnificent *Dracænas* staged by Mr. Wills. They consisted of *D. Weismanni*, a slender-habited plant, with bronzy-crimson-margined leaves; *D. Baptiste*, with broad bronze-green and brown foliage; *D. Mooreana*, well known as one of the best of all dark-leaved kinds; *D. Sheppardi*, a plant of robust habit, the bright green oblong leaves of which are irregularly streaked or margined with orange-red; also *D. amabilis*, *D. regina*, *D. excelsa*, *D. Youngi*, and the bronzy-black-leaved dense-growing *D. Dennisoniana*. Mr. Williams, of Holloway, and Mr. H. Ley, of Croydon, had also well-grown and interesting groups of new or rare foliage plants. In the first-named collection we noticed *Dracæna Fraseri*, a robust dark purple-leaved form with crimson-margined foliage; *D. amabilis*, *Ficus Parcelli*, a fine plant, 5 feet in height, and bearing small hairy fruit; *Croton majesticum*, and the bright golden variegated *C. Weismanni*; also excellent plants of the crimson-flowered *Dipladenia Brearleyana*, *Aralia Veitchi*, *Kentia Mooreana*, and the delicate fresh green-leaved *Adiantum gracillimum*. From Mr. Ley came a small but well-grown group, in which were a robust, pectinate, fresh green *Zamia Lindenii*, *Gymnogramma decomposita*, an elegantly cut gold Fern, *Martinezia erosa*, and a very distinct and effective pinnate-leaved Palm named *Calamus Puyano*, a kind with an elegant drooping habit and stout petioles, formidably armed with stout brownish spines arranged in interrupted whorls. Mr. Legge, Mr. Chapman, and Mr. Child, also furnished effective groups of foliage plants.

Azaleas and Cape Heaths.—These were both fairly represented, the plants of which the different collections consisted being mostly the same as those described in our last number. The principal prizes for Azaleas were won by Mr. A. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham, who had remarkably well-flowered plants.

Roses in Pots.—These were fairly represented, the principal exhibitors being Messrs. Paul and Sons, of Cheshunt, and Mr. C. Turner,

of Slough. In the amateur's class Mr. Ellis staged unusually well-grown pot Roses, which were deservedly much admired both by judges and visitors. Messrs. Paul furnished well-bloomed plants of Celine Forestier, Edward Morren, a fine full rosy variety; Paul Verdier, deep rosy-purple; Madame Willermoz, white; Madame Victor Verdier, rich velvety-crimson; Charles Lawson, deep rich rose; Madame Margottin, pale sulphur; Camille Bernardin, rich deep crimson; and Alfred Colomb, rosy-crimson. Mr. Turner had La France, a charming Rose of a delicate peach colour; Miss Ingram, a distinct blush-white variety, and very fragrant; Madame Margottin, Celine Forestier, Charles Lawson, and Juno, all well-known and deservedly favourite Roses. In the class for twenty specimens Mr. Turner contributed a well-bloomed group, the most remarkable plants in which were Celine Forestier, Anna Alexieff, and Madame St. Joseph. Mr. Ellis furnished six superbly-flowered specimens of John Hopper, Souvenir d'un Ami, General Jacqueminot, La France, Celine Forestier, and Victor Verdier. Mr. J. Moorman was a very good second with somewhat smaller plants, including an excellent example of the new white Hybrid Perpetual Madame Lacharme, bearing eleven blooms, Beauty of Waltham, Madame Willermoz, and Anna Alexieff.

Orchids.—Of these, Mr. B. S. Williams and Messrs. Jackson both had beautiful groups, and Messrs. Child, Ward, and Budd represented the amateur growers. Mr. Williams had good specimens of *Cattleya Mossiae* superba, *Odontoglossum citrosimum* roseum, with three fine spikes; *Dendrobium crystallinum*, *D. densiflorum*, and well-bloomed plants of *Anguloa Clowesii*, *Laelia purpurata*, and *Odontoglossum Pescatorei*. Messrs. Jackson contributed good plants of *Vanda suavis*, *Cattleya Mossiae*, and *C. Mendellii*, all very effective, *Dendrobium Parishii*, *D. macrophyllum*, and the always welcome *Odontoglossum citrosimum*. Mr. Morse, of Epsom, had well-bloomed plants of the snow-white Lady's-slipper (*C. niveum*), *C. caudatum*, *C. Loweii*, and the now seldom seen *Camarotis purpurea*. In the amateur's class, Mr. Ward had *Pescatorei's* *Odontoglossum* well bloomed; a superb specimen of the glossy brown-flowered shaggy Lady's-slipper, *Phalanopsis grandiflora*, in fine condition; the golden-flowered *Oncidium ampliatum*; and the *Odontoglossum vexillarium*, bearing seventeen rosy flowers, described in our last week's report. Mr. Child staged *Trichopilia coccinea*, *Aërides Fieldingii*, *Vanda suavis*, and an attractive plant of *Dendrobium Farmeri*. Mr. Budd, Heatherfield, Sydenham Hill, had *Phalanopsis grandiflora*, *Oncidium phymatochilum*, and a good plant of *Oncidium ampliatum majus*.

Table Plants.—Among these were some fine specimens, many of which had the surface of the soil covered with *Selaginella* and small Ferns. Mr. T. Lambert, gardener to H. W. Segeleke, Esq., Herne Hill, had elegant little specimens of *Cocos Weddelliana*, *Dracaena gracilis*, *Adiantum cuneatum*, *Thrinax elegans* (one of the prettiest of all the fan-leaved Palms), *Calamus palimbanicus*, and the yellow-striped *Hyophorbe Verschaffeltii*. Mr. Wills and Mr. Hudson, Champion Hill, were equal second, and Mr. G. Wheeler had a very well grown collection. Mr. Wills had *Terminalia elegans*, *Croton Weismanni*, a good plant for the purpose, as its netted leaves shine like burnished gold under artificial light; and *Aralia Veitchii*. In Mr. Hudson's group we noted a good *Pandanus Veitchii*, which looks well under gaslight, the elegantly-cut green-leaved *Jacaranda mimosæfolia*, *Croton Johannis*, and *Euterpe edulis*—the last, when young, one of the most attractive of small Palms. Mr. B. S. Williams furnished an effective little group; in which were *Pandanus Veitchii*, *Aralia Veitchii*, and the still more elegant *A. leptophylla*, *Cocos Weddelliana*, *Dracaena Baptistii*, and *Kentia Fosteriana*, an elegant Palm.

Miscellaneous Subjects.—Messrs. Jackman, of Woking, sent a well-grown group of new and beautiful Clematises in pots; among which the following were remarkable, viz., *J. P. Gassioti*, a large six to eight-petalled flower, nearly white suffused with soft lilac; *Mrs. Hope*, a delicate lilac; *Fair Rosamond*, white shaded with lilac; and *The Queen*, a fine six-sepalled flower of a delicate lilac-purple colour. Mr. Wills staged an attractive collection of new and rare decorative plants, consisting of Ferns, Palms, Dracaenas, and *Cephalotus follicularis*. Mr. B. S. Williams had also an effective group, in which there were new and rare Ferns, Palms, Orchids, Cycads, and other decorative plants. Mr. John Laing, Forest Hill, contributed a well-arranged group of stove and greenhouse decorative plants, and some fine-foiled bronze and zonal Pelargoniums, which were much admired. Messrs. Jackson showed a group of the white-flowered *Saxifraga nepalensis*, which had been grown in the open air, and merely sheltered from rain when the flowers were about to open. Messrs. Carter & Co., of Holborn, staged a well-grown group of their new pyramidal *Mignonette*, and a fine basket of *Coleus Duchess of Edinburgh*, one of the most beautiful kinds ever introduced to our gardens. A good collection of hardy herbaceous plants came from Mr. Parker, of Tooting, and Mr. Ware, of Tottenham, had some excellent blooms of Pansies, as did also Mr. Hooper. Mr. R. Collier, gardener to R. H. Bristowe, Esq., Wavertree, near Sydenham, furnished half-a-dozen pans of *Selaginellas*, among which were *S. hortensis*, *S. rubicaulis*, *S. umbrosa*, *S. Mertensi* and its variegated variety. Some highly-coloured and compact-habited herbaceous *Calceolarias* came from Messrs. Dobson & Sons, of Isleworth; and Mr. Waters, gardener to A. Mongredien, Esq., also sent a well-grown group of these popular summer decorative plants. Mr. James showed six splendidly grown fancy Pelargoniums, the finest in the exhibition; and a variegated-leaved fancy Pelargonium, named *Alice*, came from Mr. Smith, nurseryman, Isleworth. Its leaves are pale green, distinctly margined with creamy-white, its flowers being white, with a bright rosy-lilac blotch. A group of seedling show and fancy Pelargoniums, all of excellent quality, came from Mr. Foster.

ROYAL HORTICULTURAL SOCIETY.

JUNE 22.

GREAT SUMMER SHOW.

CONSIDERING the financial difficulties with which the Society is beset, and the reluctance with which prizes already won have been paid, this was a much better exhibition, of both fruits and flowers, than might have been expected. New plants, indeed, were unusually numerous and striking, and, as in these the principal interest seemed to be centred, we will begin our report with them.

First-class Certificates were awarded, on this occasion, to the following:

Clematis Lord Nevill (Cripps).—This is a vigorous-growing variety, with large pale green foliage, and crisped eight-sepalled flowers, each 5 inches in diameter. The colour is a rich velvety-blue, each segment having a purplish bar down its centre. It is one of the most distinct and promising of the new kinds.

Polystichum lepidocaulon (Williams).—This a distinct and effective Fern, sometimes called *P. Hookeri*. In habit it reminds one of a *Cyrtomium*, the simple rhomboidal pinnæ being of a bright glossy green, and the rachis curiously prolonged into a caudal proliferous appendage.

Oncidium curtum (Bull).—A free-flowering and beautiful Orchid, with ovoid two-leaved bulbs and an erect branched spike of brown spotted flowers, the lip of which is of a rich golden-yellow margined with brown spots, the calli being rich purple. In shape the flowers remind one of those of the well-known *O. sarcodes*, but the plant is quite distinct from that kind.

The following received Second-class Certificates:

Pelargonium Prince of Wales (Bull).—A robust-habited semi-double variety, with bright rosy-scarlet flowers of a velvety texture, having a whitish eye. It has a dense habit, and looks as if it would prove a useful free-flowering kind for decorative purposes.

Lilium Hansoni (Wilson).—This is a beautiful Japan Lily, fully 4 feet in height, having bright green leaves in whorls, and bearing seven or eight bright orange-yellow brown-spotted flowers in a terminal spike. It appears to be nearly related to *L. maculatum* or *L. avenaceum* of the "Botanical Magazine," and is, in every respect, a first-class Lily, and one which is likely to become a general favourite.

Clematis Lady Alice Nevill (Cripps).—A distinct and effective variety, robust in habit, the foliage being of a bright glossy green. It has eight-sepalled flowers, which are about 6 inches in diameter, of good form, and freely produced, the colour being of a delicate lilac or mauve-purple.

New Plants.—Mr. Bull deservedly obtained the premier award for the best group of twelve new plants, conspicuous among which were *Croton majesticum*, remarkably well coloured; *Aralia Veitchii*, nearly 5 feet high, and well furnished to the base; *Kentia Mooreana*, from 4 to 5 feet high, its gracefully-arched foliage being of a deep glossy green; *Anthurium crystallinum*, with velvety green leaves, veined with silver; *Dracaena Hendersonii*, with bright green foliage, splashed and striped with rosy-lilac and creamy-yellow; *Phyllotanium Lindeni*, a broad-leaved Arad, 4 feet in diameter, its hastate leaves being deep green, boldly veined, and netted with ivory-white; *Croton imperiale*, a glossy, blunt-leaved, and distinct habited plant, well furnished with green leaves, margined with golden-yellow, the mid-rib being of a bright rosy hue; *Dracaena Goldiana*, a distinct and effective plant, with oblong or cordate deep green leaves, banded with zebra-like stripes of silvery-grey; *Pritchardia grandis*, a deep glossy green, dense habited, fan-leaved Palm, as rare and valuable as it is effective and distinct; *Dracaena Baptistii*; *Pleocnemia Leuzeana*, a distinct and delicately-cut Fern; and *Croton spirale*, a bronzy-green-leaved species, each leaf twisted like a corkscrew. Mr. W. Bull also staged *Odontoglossum Roezlii album*, a new Orchid, to which the first prize was awarded. In the class of six new plants the same exhibitor also obtained the first prize. In this exhibition we noticed *Blandfordia princeps*, a distinct grassy-leaved plant, with erect spikes of bright orange-yellow flowers; *Croton picturatum*, an elegant drooping plant, with yellow-spotted bright green foliage, hastate at the base; *Pritchardia grandis*, *Dracaena Goldiana*, *Lomaria dobroydensis*, and the white-margined *Dracaena canescens*. For a single new plant in flower Mr. Bull was likewise first with the new *Blandfordia princeps*, in admirable condition. Mr. Bull, in the class of six new Crotons, showed beautiful plants of *C. spirale*, *C. majesticum*, *C. undulatum*, finely coloured; *C. volutum*, each leaf curled like a ram's horn; *C. Weismanni*, and *C. Youngei*. These plants, to which a first prize was awarded, varied in height from 2 to 3 feet, and were about the same in diameter. Amongst other rare plants, Mr. Bull showed examples of *Anthurium Scherzerianum album*; *Pilocereus senilis*, a scarce Cactaceous plant, usually called the Old Man Cactus, covered with long white hair; and several new Palms.

New Plants sent out since 1872.—For the prizes offered by Mr. Bull, under this head, several competed. Messrs. Thynne, of Glasgow, were first with excellent examples of *Dracaena Shepherdii*, *D. Fraserii*, *Croton majesticum*, *Macrozamia plumosa*, *M. spiralis eburnea*, *Encephalartos villosus ampliatum*, and others. Mr. Wimsett was second with a well-grown group, in which we noted the finest *Maranta Makoyana* we have ever seen, a good plant of *D. Fraserii*, and an excellent *Dæmonorops palimbanicus*. In the amateur's class, Mr. Croucher was first with well-grown specimens of *Dieffenbachia nobilis*, 5 feet in height; *Dæmonorops palimbanicus*, a splendid specimen, 12 or 14 feet in height; *D. metallica*; *Kentia canterburyana*; and the elegant pinnate-

leaved *Guilielma utilis*, one of the most useful of new Palms. Mr. C. Legge was second. In the class for growers who have not previously won any of Mr. Bull's prizes, Mr. C. Legge was first with a well-grown group, in which were a well-flowered specimen of the bright rosy-crimson *Dipladenia Brearleyana*, *Dracæna Baptistii*, *D. Shepherdii*, *Dieffenbachia nobilis*, *Croton majesticum*, and others. Mr. Coomber, gardener, Fitzroy Park, Highgate, was second; and Mr. E. Pilgrim third. A similar prize set apart for nurserymen who have not previously taken prizes offered by Mr. Bull, was awarded to Mr. Wright, Lee, Kent, for a really excellent group of plants, among which were *Maranta Makoyana*, *Dæmonorops palimbanicus*, *Croton majesticum*, and others.

Stove and Greenhouse Plants.—Mr. Kemp, Albury Park, Guildford, showed a well-arranged group of half-specimen plants, the best among which were *Aphelexis macrantha purpurea*, 2 feet through; *Hedera tulipiferum*; well-bloomed plants of *Acrophyllum venosum*; *Boronia serrulata*, 2 feet in diameter; *Clerodendron Balfouri*, *Dracophyllum gracile*, and *Erica Cavendishiana*. Four splendid specimens of *Dicksonia antarctica* came from Mr. Wills; their trunks, which were 8 or 10 feet in height, were just throwing up magnificent crowns of fresh green fronds. Half-a-dozen large specimen *Azaleas* came from Mr. Ratty, The Hoo, Sydenham, who had *Burlingtoniana*, a fine bright semi-double rosy variety; *Iveryana*, white; *Criterion*, pale rose, margined with white, and delicately spotted; *Extrani*, bright rose; and others. In the nurserymen's class for eight plants, Messrs. Ivery, of Dorking, were first with well-flowered plants, among which were *Flag of Truce*, one of the best double white kinds; *Chelsoni*, scarlet; *Forget-me-not*, silvery rose; *Charles Encke*; *Tricolor*, white, striped with pale scarlet; and *Oracle*, a distinct small round-petalled flower, of a bright rosy-lilac colour, and very effective. Messrs. Ivery had also a well-flowered group of smaller plants. In the class for twenty fine foliage plants, Mr. Bull was first with well-grown plants, artistically grouped for effect. Among these, the most striking were *Pandanus Veitchii*, *Croton Veitchii*, *Aralia Veitchii*, a superb specimen; *Dracæna lentiginosa*, with purplish foliage and a habit similar to *D. australis*; *D. Goldiana*, *D. regina*, *D. ferrea variegata*, brilliantly coloured; *Croton Weismanni*, 4 feet in height and well coloured; *Geonoma Seemanni*, and *Paullinia thalictrofolia*, a shield-shaped plant, fully a yard across. In the same group were also fine plants of *Dion edule*, with soft glaucous pectinate leaves; *Phormium Colensii variegatum*, *Cycas imperialis*, with delicate light green frond-like leaves; *Dæmonorops cinnamomeus*, *Cocos nucifera*, *Cycas revoluta*, and the novel-looking *Bowenia spectabilis*. Mr. Wills showed a fine collection in the same class, in which there were, besides many others, *Cicca disticha*, a bright green-leaved plant, with pinnate foliage, and a habit similar to that of a *Sumach*. *Xylophylla latifolia*, with fresh green pinnate leaves, the margins of which were fringed with tiny flowers; *Aralia fastigiata*, with distinct Ivy-green drooping leaves; *Aralia pulchra*, with long-stalked umbrella-shaped clusters of radiating glossy leaflets; *Cocos Weddelliana*, *Cycas revoluta*, *Curculigo recurvata variegata*, and others. Of Palms, good collections came from Mr. Wimssett and Mr. Bull. The former had *Cocos Weddelliana*, *Geonoma Verschaffeltii* (a fine decorative Palm, with irregular cut foliage, the young growth being tinted with purplish-brown), good plants of the graceful *Thrinax elegans* and *T. elegantissima*, *Latania rubra*, *Areca lutescens*, and *Calamus palimbanicus*. In Mr. Bull's group were the rare *Acanthorrhiza Warszewiczii*, a distinct habited Palm, of *Licuala*-like growth, the upper surface of its radiate foliage being of a bright and glossy green, and the under surface silvery or glaucous. In the same group were handsome specimens of *Verschaffeltia splendida*, *V. melanochætes*, *Oncosperma Van Houtteana*, *Thrinax nobilis*, and others. In the class of six decorative Palms Mr. Wills was first with large specimens of *Latania borbonica*, *Chamaerops humilis*, *Hyophorbe Verschaffeltii*, *Seaforthia elegans*, and others. Of *Dracenas* Mr. Bull had a beautiful collection, in which were good specimens of *D. Baptistii*, the foliage of which is regularly spiral; the rare and distinct *D. Goldiana*, fully 2 feet in height, the zebra-like markings of grey on a dark greenish ground being very bright and effective; also fine plants of the robust-habited *D. Fraseri*, *D. regina*, *D. Mooreana*, *D. Weismanni*, *D. Rex*, *D. Shepherdii*, *D. amabilis*, *D. magnifica*, and the slender bronzy-leaved *D. triumphans*. Mr. Wills furnished a good group, for which a second prize was awarded. Mr. Douglas, Loxford Hall, staged two effective collections of Orchids, among which we remarked the rich lilac-tinted *Masdevallia Harryana*, two plants of the crimson or blood-coloured variety named *M. Whitbourniana*; two strong plants of the North American *Cypripedium spectabile*, on one of which were four large and rich rosy-lipped flowers; the chaste *Dendrobium Bensoniæ*, represented by two well-flowered plants; and there was also a robust *Cattleya Warnerii*, with five or six strong spikes of lilac-sepalled purple-lipped flowers. Associated with these were also good examples of *Dendrobium thyrsiflorum*, *D. Farmeri*, a well-flowered *Oncidium ampliatus majus*, and a strong plant of the singular long-tailed *Oncidium phymatochilum* bearing a branched spike fully 4 feet in length. Cycads were shown by Mr. Croucher and Mr. Bull.

Miscellaneous Subjects.—From Mr. W. Bull came six small potfuls of well-bloomed Lilies. Mr. Parker had, among hardy plants, fine examples of crimson, rose, and rosy-scarlet varieties of *Pæonia officinalis*; the snowy-white-flowered *Iberis corifolia*; *Cypripedium spectabile*, *Lupinus polyphyllus magnificus*, with five spikes of bluish-purple flowers; a good plant of the elegant *Thalictrum rubrum*, and some *Pyrethrums*. Mr. Dean, of Ealing, contributed *Campanula garganica*; the lovely blue *Lithospermum prostratum*; *Scilla Peruviana alba*; *Viola Mulberry*, a free-flowering bedding variety of a maroon-purple colour; *Aquilegia chrysantha*; and others. Mr. Dean had, also, cut spikes of the giant white *Brompton Stocks*, which were very fine, and

deliciously fragrant. Messrs. Ivery and Parker had fine collections of Hardy Ferns. Mr. B. S. Williams furnished a well-arranged group of flowering and foliage plants, to which a silver medal was awarded. A gold medal was awarded to Mr. Wills for a fine bank, of about 100 feet in length, consisting of Palms, Orchids, Ferns, *Dracenas*, and flowering plants, the whole margined with *Creeping Jenny*, which imparted quite a novel and pleasing effect to the arrangement. Messrs. Veitch & Son staged an effective group of *Ixias* and *Sparaxis*, *Iris*, and other bulbous plants, the colours being rich and distinct. Mr. Bull sent a new velvety-scarlet *Pelargonium*, with a pale-coloured eye; to which a second-class certificate was awarded, and the same exhibitor also showed two plants of his new *Pelargonium Beauty of Oxtou*. Messrs. Kelway & Sons, Langport, contributed two fine stands of *Pyrethrum* flowers, as did also Mr. Parker, who had, moreover, a beautiful collection of cut blooms of German *Irises*. Messrs. Cripps & Son, Tunbridge Wells, showed some striking new *Clematises* in excellent condition, conspicuous among which were *Maid of Kent*, a sturdy habited plant with deep green leaves, and satiny-lilac or mauve-tinted flowers 6 inches in diameter, well borne up on stout stalks; *Duke of Edinburgh*, a vigorous plant with rich violet-purple six-sepalled flowers; and *Blue Perfection*, a free-flowering pale bluish-lilac variety of good form, the sepals being flat and neatly rounded. The same exhibitors also showed a new *Cratægus* named *C. filicifolia*, a kind with tender green-lobed foliage, elegantly fringed, and *Quercus striata*, a Japanese variegated variety, with coarsely-serrated lance-shaped deep green foliage, banded with paler green. Messrs. Barron, Elvaston Nurseries, Borrowash, had *Cupressus Lawsoniana elegantissima*, a beautiful golden form of the *Lawson Cypress*; also *Retinospora tetragona aurea*, and a miscellaneous collection of Conifers, among which were *Abies Sieboldi nana*, *Chamaecyparis sphaeroidea aurea*, and *Picea (Abies) concolor*, a kind intermediate, apparently, between *P. nobilis glauca* and *P. Parsonii*; it is an effective glaucous-leaved American species, discovered by M. Röezl. G. F. Wilson, Esq., of Heatherbank, Weybridge, sent *Lilium Hansonii*, a variety with bright green whorled leaves and a terminal spike of bright orange-yellow flowers spotted with dark brown; it seems nearly related to *L. avenaceum*, and, like that species, the style is slightly declinate. A second-class certificate was awarded to it. Mr. Thomson, Clovenfords, sent a splendid cut spike of *Vanda suavis*, bearing nineteen fully-expanded flowers, which are said to remain four or five months in perfection. Messrs. Veitch staged their new hybrid *Cypripedium selligerum*.

Fruit and Vegetables.—For Muscat of Alexandria Grapes Mr. W. Bones, gardener to D. McIntosh, Esq., Havering Park, was first for medium-sized well-coloured clusters. Mr. Douglas, of Loxford, also showed some well-finished bunches in the same class, likewise three well-coloured bunches of Buckland Sweetwater, for which a first prize was awarded. Mr. T. Bannerman was first in the open class with Foster's Seedling which was good for the season, and Mr. Douglas was second with Canon Hall Muscat, the berries of which were large and fine. Mr. Earley obtained the first award for Red Frontignans. Mr. A. Grant, gardener to J. B. Glegg, Esq., Withington Hall, Cheshire, was awarded a first prize in the open class for a fine Sugar-loaf Pine, Mr. F. Miles being second with a good Queen; the last-named exhibitor also had the best two Smooth Cayennes shown, and a good fruit of the same variety came from Mr. Harris, gardener to Mr. J. H. Vivian, Singleton, Swansea. To Mr. Douglas was awarded a first prize for Black Hamburg Grapes, and Mr. Brush, gardener to Lady Hume Campbell, who was second, also had finely-ripened bunches of the same variety. Mr. Gilbert, of Burghley, obtained a first prize for Melons with Read's Hybrid Scarlet-flesh, and Colston Bassett Hybrid in the class for green-flesh. Mr. Stevens, gardener to J. B. Elliott, Esq., was second in both classes with Oulton Park, green-flesh, and Malvern Hall, scarlet-flesh. Mr. Miles was first both for Peaches and Nectarines, with good dishes of Stirling Castle and Elrue. The same exhibitor was also awarded a first prize for black and white Cherries, the kinds being Black Circassian and Elton; and he also obtained a first prize for Figs with Brown Ischia. Mr. Pottle, gardener to Sir R. Wallace, Sudbourne Hall, Derby, was second with White Marseilles. Mr. Douglas received a first prize for twenty-five Strawberries, the variety being British Queen, and Mr. Douglas was also first with President. Mr. Miles staged a fine basket of Chillies and a box of large Tomatoes, for which an extra prize was given. In the class of six dishes of Peas shown for Messrs. Sutton's prizes, Mr. Pragnell was first with William the First, First Crop Blue, Sutton's Emerald Gem, Sutton's Ringleader, McLean's Little Gem, and Sutton's Bijou. Mr. Brown was second with Blue Peter, Prizetaker, Early Premium Gem, Little Gem, and White Gem. For the four best sorts of Melons and four sets of Cucumbers, shown for prizes also offered by Messrs. Sutton, Mr. Read, The Gardens, Arley Hall, Northwich, was first, with Melons—Golden Perfection, Hero of Bath (Sutton), Read's Hybrid, and Sutton's Royal Horticultural Prize; Cucumbers—Duke of Connaught (Sutton), Marquis of Lorne (Sutton), Tender and True (Veitch), and Telegraph (Rollisson). For the prize offered by Messrs. Carter & Co. for Peas, Mr. Pragnell was again first, with Carter's First Crop, Maclean's Blue Peter, Extra Early, Premium Gem, William the First, Carter's White Gem, and Laxton's Unique. Mr. Gardiner, Lower Ealington Park, Stratford-on-Avon, sent a dish of Grosse Mignonne Peaches; Mr. Booth, Osmaston Manor, furnished several Melons; Messrs. Carter sent samples of their new Fern-leaved garnishing Parsley—alluded to in another column. A new Plum, called Improved Orleans, came from Watt's, Devizes, and is said to be well adapted for pot-culture; Mr. Batters, gardener at Chilworth Manor, sent a very fine smooth-leaved Cayenne Pine-apple.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

A BEAUTIFUL ROCK-GARDEN.

A REPRODUCTION of some of the grandest forms of Nature on a greatly reduced scale, without losing their breadth or character, is the secret of the successful creation of artificial rock-work. In mountains the scale is generally so gigantic that actual reproduction would be impossible. What should, therefore, be aimed at is to copy, on a small scale, the great features of the original, as a miniature painter would represent on 4 square inches of sheet ivory one of the vast gallery pictures of Rubens. Attempts are sometimes made in rock gardening to turn to account the natural rocks which may occur on the spot ready to the hand of the landscape gardener; but rocks thus presenting themselves are not always easy to deal with in this way. Their surfaces, in all probability, present too small a number of fissures and irregularities for the reception of the plants with which it is sought to clothe them, and very large bare places will be the result. In an Alpine valley the scale is so enormous that vast spaces of naked rock form a picturesque contrast to the intermediate spaces luxuriantly clothed with many forms of Alpine vegetation. But within the limits of a rock-garden, on even a very extensive scale, there is little room for great spaces which must necessarily remain useless as regards the purpose in view—that is, the formation of an area suitable for the growth of a rich collection of Alpine plants. Rocks that crop up in a garden, when left to themselves and only planted with a few Ferns and Brambles, or scattered with the seeds of Wallflowers and wild Pink, can scarcely be overrated as picturesque and valuable adjuncts to the wilder portions of open ground in shrubberies. When it is sought to make them the nucleus of a rocky Alpine garden, perfect success is not often achieved, and with good taste, horticultural knowledge, and a natural sense of the picturesque, better results may often be obtained by purely artificial means. I have been led to these remarks by the present appearance of the finest mass of purely artificial rock-work that it has ever been my good fortune to meet with. I might, indeed, have spoken in the plural, and said masses, for the noble composition of rocky scenery I am alluding to contains several distinct chasms or valleys, above which rise great angular pinnacles, grouped in a natural and effective manner; while, in the deepest parts, small sheets of water occur, in which some of the boldest portions of the work are reflected with charming effect. All this is, however, quite secondary to the exquisite clothing of Alpine vegetation with which these masses of rock are by skilful management so abundantly and luxuriantly clothed. I say skilfully, with due appreciation of the value of the word, because much more than merely persistent and plodding care has been exercised in the production of such a result. The faces of the different portions of rock have been made to present themselves to every variety of aspect, so that each plant may enjoy the amount and duration of sunlight that its constitution requires. There are sheltered and cave-like nooks for modest and delicate plants that under a scorching sun would perish. Near the water, great depths of peat soil or rich loam are provided for moisture-loving plants of various kinds, each being provided with its exact requirements; while, in parching weather, artificial showers from invisible fountains gently moisten the more exposed portions of the work like a gentle rain. But, as I have said, these picturesque and at the same time skilful preparations for a rocky Alpine garden become quite secondary to the garden itself when the brilliant masses of Alpine flowers, now in their greatest luxuriance, meet the eye. The great variety of these choice gems of the vegetable kingdom, which have been here brought together and made to flourish as luxuriantly as in their native regions, is so extensive and so interesting that their home is not long dwelt upon after the first glance. Its perfectly natural appearance is perhaps one of the chief causes of this. We find ourselves in a beautiful rocky valley, filled with the

loveliest Alpine flowers which at once arrest and rivet the attention. The lovely mountain *Myosotises*, the flowers large and beautiful, and softly blue, luxuriate in the crevices of these rocks; and, flowering, as they do, close down among their foliage, which clings to the stone, they resemble large jewels formed of masses of turquoises. There is another closely allied plant, also in flower at the present moment, which nearly eclipses this mountain *Forget-me-not*. It is the lovely *Eritrichium nanum*. Its flowers very closely resemble those of the *Forget-me-not*, being of the same soft blue colour, though perhaps slightly deeper in tone, the flower being almost identical in other respects. The chief peculiarity distinguishable at a glance is the exceeding smallness of the foliage, the leaves being so narrow and close-growing that they form a tuft, like a clump of Moss, upon which the flowers are thickly set, and are crowded so closely together as nearly to conceal the foliage. Conspicuous objects, too, are the abundantly-flowered clumps of mountain Pinks, especially *Dianthus glacialis*, the flowers of which are as large as a shilling, of bright metallic rose colour delicately marked, and so abundant that on their short foot-stalks, not 2 inches high, they form a crowd of flowers, literally two deep, over the whole plant, each flower half covering the other. *Dianthus neglectus* is an equally compact and free bloomer, and, by its greater depth of colour, forms a charming contrast to *glacialis*. *D. alpinus* is another species of a similar character, quite distinct in both leaf and flower from any other. A score of other beautiful species of this genus, of a more or less Alpine character, are now in full bloom on this rockery. A patch nearly a yard across, of a beautiful azure *Pentstemon (humilis)* is formed by a mass of exquisite little plants scarcely 3 inches high, of most attractive aspect. The face of the rock in some places is quite golden with the bright yellow of the dwarf Alpine Wallflower, growing almost as closely to the rocks as a Lichen. On the face of other stones of this picturesque pile the *Pinguicula* raises its erect stem from the solid rock itself with apparently no other root-hold than the pores of the stone. In lower and moister places, several species of *Trollius* flourish, especially a new and double variety of brilliant orange-chrome colour. There are two large clumps of the rare English Orchid, *Cypripedium Calceolus*, in one of which I counted thirty blooms, and the plants were growing so vigorously, that many of them had two and three flowers on a stem. The fine Siberian *Cypripedium*, crimson-flowered, and perfectly hardy, was flowering in another nook. Several other kinds of terrestrial Orchids form fine patches of rich purple at various points, some of them being extremely rare. Tufts of rock *Cistus* of many colours are everywhere covered with showers of bloom—some white, some orange, whilst others are yellow and brilliant rose colour. Nearly all the mountain Poppies—yellow, orange, and white—too, are now in their glory. Large masses of *Lithospermum prostratum* appear in conspicuous places, and the intense metallic blue of the flowers is almost too dazzling to look upon. But it is useless to attempt an enumeration of the Alpine plants now in bloom here, almost every genus of that class of plants being represented in this magnificent collection; one or two more, however, I must mention:—The beautiful *Edraianthus*, bearing a *Campanula*-like flower, but with delicately-slender glaucous foliage, almost thread-like in form, represents a genus which will form a valuable addition to the list of rock plants. The bell-flowers are of a peculiarly graceful form—there are three species in bloom here, one a dark purple, and the other two of distinct shades of soft lavender. Another extremely attractive and very neat-growing little plant is *Æthionema coridifolium*, closely related to the *Iberis* family, but more beautiful than any of them. Another attraction to me was the very pretty dwarf *Ramondia pyrenaica*, and lastly the interesting little dwarf Lily, *Lilium kamschatcense*, scarcely 3 inches high, the flower being of an intensely dark ruddy-brown, with large brilliant yellow anthers glistening in the depths of the bells like sparks of fire. It is needless to add that an immense variety of graceful hardy Ferns, many of which I had not seen before, add a feathery grace to the rocks of this miniature Alpine region. It is, without doubt, the most beautiful and extensive rock Alpine garden planned. It is the unaided creation of Mr. James Backhouse, and

is the result of eighteen years of skilful planning and incessant working, and the story of its development is quite an "art romance." The carriage of the great masses of rock from considerable distances; the invention of rough but effective machinery for lifting them finally into their respective positions; the break down of the lifting machine just as one of the heaviest stones was nearly raised to the apex of one of the compartments, and was suddenly hurled "in horrid ruin and confusion down;" and the overcoming of a thousand other difficulties, would form a very interesting chapter in the annals of horticulture.

H. N. H.

York, June 9.

Garden Sticks and Labels.—About thirty years ago, labels, cut out of sheet zinc in triangular and rectangular forms, were sold by a Mr. Thompson, of Fenchurch Street, London (both name and address, I believe, I give correctly), together with a fluid for writing on them, the ingredients of which were given to the public a few years later in one of the horticultural periodicals of the day, and are the same as those given at p. 397 of THE GARDEN. Of late years, Mr. Yeats, of Mortlake, has improved upon these labels, both in the variety of their form and in the brilliancy of the fluid which he supplies with them. I cannot but think it a great benefit to the grower to be able to put on his labels any name he pleases, an advantage those of Mr. Yeats possess in common with Messrs. Maw's terra-cotta labels mentioned in my former communication, and with the wooden labels of Messrs. Blackith, of Cox and Hammond's Quay, Lower Thames Street, whom, for want of knowing his useful productions, I was then unable to mention. He provides both labels and garden sticks; the former in the two forms required for pots and patches of flowers, and for attaching to trees; the latter of all heights, from one foot and upwards, for plants that require support. Although both sticks and labels can be easily made out of stout laths, selecting the straightest for the sticks, I doubt if many persons could be found who would not prefer getting them ready made from Messrs. Blackith at the very moderate price at which they are offered. The sticks will be found especially useful, and well worth their price. I have lately ascertained that the modern zinc label, now sold by seedsmen and others, originated with Mr. Yeats, and was introduced by him sixteen years ago; to his neatly furnished plant markers I was unable to make anything more than a passing allusion when I last wrote on this subject. It is only right that he who originates should have, not only the full credit of invention, but also the largest share of public favour.—B. S.

Haricot Chocolat.—Now, when the different ways of forcing French Beans, and the different varieties suited for that purpose are attracting much attention, it may be well to mention that the above named variety has proved the most productive for forcing in the neighbourhood of Paris, according to the last "Journal of the Central Society of Horticulture of France." We hope Mr. Gilbert, Mr. Temple, and others of our good forcing gardeners, will try it.

Thorn Trees Leafless for a Year.—Last summer, being exceptionally hot and dry, a number of red and white Thorns, planted in clumps in the Park here, did not put forth leaves, and were apparently dead. This year, however, they are all bursting into leaf, and are none the worse for a season's rest. The same thing sometimes happens with Apple and Pear trees, therefore, as long as the wood continues fresh, such trees should not be destroyed.—J. GROOM, *Henham Hall, Suffolk.*

Horse-radish Poisonous to Cattle.—An instance of cows being made violently ill, and one killed, from eating a few roots of Horse-radish thrown out of a garden is given in the "Rural New Yorker" for May 15th.

Fruits that Thrive in Nova Scotia.—Mr. C. E. Brown, of Yarmouth, N.S., after many trials, says the following Apples, out of all the varieties of the Crabs, are the only sorts that can, so far, be recommended for the coast lines and the cold regions of the province, namely, Duchess of Oldenburgh, Gravenstein, Green Sweet, Hubbardston Nonesuch, Keswick Codlin, Primrose, and Wagener.

The Judas Tree (Cercis Siliquastrum).—This and its white variety, as well as *C. canadensis*, are now amongst the most effective of flowering shrubs in lighting up our shrubberies. Bushes of these studded with rich masses of their lovely Pea-shaped blossoms are most attractive, and it is surprising how seldom they are met with in shrubberies, where their distinct inflorescence is remarkably effective. These deciduous trees grow freely and compactly, forming famous bushes in sheltered places, and I do not see, therefore, why it is so sparsely distributed.—G. WESTLAND.

Bertolonias.—Of these M. Van Houtte has raised three charming hybrid varieties, all plants with short erect stems, bearing large opposite ribbed leaves, beautifully striped and spotted. B. Van Houttei has large leaves, possessing a rich velvety ground colour, traversed lengthwise by distinct bars of beautiful magenta, and dotted all over with hundreds of spots of the same colour. B. Mirandæi is similar to the foregoing, only the leaves are not marked with bars, but are uniformly dotted with crowds of magenta spots on a dark olive-velvet surface. B. Marchandii has dark velvety leaves, striped with silver bars. These Bertolonias are remarkable for the brilliancy of their markings, which are strikingly beautiful.—M.

Stealing Alpine Plants from the Royal Botanic Gardens, Edinburgh.—A man named Murray, residing at Durie, Fife, was charged the other day with stealing fifty Alpine plants from the Botanic Gardens, Edinburgh. Accused pleaded guilty, was fined £5, with the alternative of fifty days' imprisonment, and ordered to procure £10 caution or suffer other fifteen days' imprisonment. The fine was paid, and the caution found.

NOTES OF THE WEEK.

— GREYIA SUTHERLANDI is now in flower in the great temperate-house at Kew. It has been much spoken of recently, but is not likely to become popular as an ornamental plant.

— STRAWBERRIES are ripe a fortnight earlier than usual, contrary to what might have been expected. Those in the London markets come mostly from Devonshire and Kent, and are, as yet, poor in flavour.

— THE thick stately stems of *Lilium giganteum* are singularly effective at this season, even long before their flowers open. In Professor Owen's garden, in Richmond Park, this Lily is again preparing to flower strongly. It seems to thrive as well as ordinary hardy Lilies among American shrubs in peat soil.

— WE have received Part I. of the "Transactions of the Massachusetts Horticultural Society," for 1875. It is, as usual, remarkable for the value of its purely horticultural matter. The society keeps to its own subjects, and does not discuss matters of merely botanical and fungological interest, and this seems to us a merit.

— OUR fruit-growing readers will find interesting matter in the paper by Mr. Hovey, of Boston, which we publish this week. It is particularly valuable in giving us the first account we remember to have seen of the best American-raised Pears. These are well worthy of a trial in Europe, already enriched by various American varieties of great value, such as Bloodgood, Seckel, and Clapp's Favourite.

— It may interest fruit-growers to know that the competition for Messrs. Veitch's fruit prizes is fixed to take place on the 21st of next month, in the Royal Horticultural Society's garden at South Kensington. The prizes are twenty-four in number, and vary from £1 to £15. They are offered for collections of fruit, and for Grapes, Pine-apples, Peaches, and Nectarines. The competition is limited to British gardeners.

— It will be seen, by an advertisement in another column, that entries for the forthcoming exhibition in the Lower Grounds, Aston Park, will close next Thursday. The profits of the exhibition are to be devoted to the building fund of the Midland Institute, where 2,000 students (chiefly artisans) are educated annually; £30,000 are required to be raised in order to extend class-rooms, &c., so as to accommodate a larger number than that just named. Of this sum £22,000 has already been subscribed.

— WARM and sunny as the weather now is Mr. Meston is busily engaged in planting Box, Hollies, Aucubas, Conifers, Phillyreas, and various other evergreens. They are prepared by well watering the balls two days before, the plants are taken up in the evening, transported very early on the following morning, the planting being effected as early as possible. Wet litter is put round the roots to prevent the destruction of the young roots by the dry air—good watering and a little shading in the case of valuable specimens, follow as a matter of course.

— THE current number of the "Botanical Magazine" contains coloured plates of the following new or rare plants:—*Kniphofia Macowani*, a dwarf form of *Tritoma* from the Cape, growing about 18 inches in height, and bearing spikes of bright orange-red flowers; *Crocus Crewei*, a pretty little Greek bulb, with small creamy-white flowers, the outer segments being yellowish behind, and streaked with purple; *Dracæna Smithii*, a rather tall-growing, green-leaved African species, bearing dense branched spikes of yellow flowers; *Balbisia verticillata*, a Chilian or Peruvian geraniaceous plant of slender habit, having whorled leaves and conspicuous bright yellow Poppy-like flowers; *Masdevallia Estradæ*, an elegant little Orchid from New Granada, having bright green spatulate leaves, and solitary white purple-blotched flowers with yellow tails, borne singly on slender scapes, 4 or 5 inches in height; *Viburnum Sandankwa*, a not particularly showy Japanese shrub, with oblong serrate leaves, and terminal clusters of whitish flowers suffused with pale rose.

— AT the Centennial International Exhibition, to be opened in Philadelphia on the 10th of next May, and closed on the 10th of the following November, every facility will be afforded for a full and complete display of fruits, as well as of models in wax and plaster of such as are perishable. Of small fruits, there will be certain classes, as Strawberries from the South, ready for exhibition on the opening day; and the variety and quantity of fruits of all kinds will be presented in an increasing scale as the season advances; but the most important display will, as a matter of course, be made during the months of September and October. Fruits of similar character will be classed together, in order that a more satisfactory conclusion may be arrived at as to the respective merits of like productions from different soils and States; thus, all Grapes, from whatever source, will be placed in one position; the same with Apples, Pears, and the entire list of cultivated and wild fruits and nuts. In this way creditable evidence of the resources of each State, in respect to fruit culture, will be furnished.

THE INDOOR GARDEN.

DICTYOGRAMMA JAPONICA VARIEGATA.

THIS, one of the rarest and best of all warm greenhouse Ferns, has been introduced to our gardens from Japan by Mr. B. S. Williams, of Holloway. With *Dictyogramma*, or, as it is more frequently called, *Gymnogramma japonica*, we have been acquainted for some years, but the plant of which the accompanying is an illustration, is a variegated variety, and quite new; its distinctive character consists in the fronds being prettily marked on both sides of the mid-rib by a series of pale green blotches, which form a striking contrast with the deep green ground colour. On young plants the fronds are from 12 to 18 inches high, furnished with one or two pairs of linear-lanceolate serrulate pinnæ, and a longer terminal one, as in *Pteris cretica*, with which, however, this has no affinity. As the plants get older and more vigorous these pinnæ divide, so that the fronds become bipinnate, the pinnules being of similar form to the pinnæ, but rather smaller, and the pinnæ and pinnules being always few in number. The venation is reticulated in the costal half of the pinnæ or pinnules, while the veinlets of the outer half running out to the margin are straight and parallel. The sori are naked, produced in transverse lines corresponding with the lines of the venation. This is decidedly one of the most effective new Ferns of the year, and it is one which is by no means difficult to cultivate. B.

PELARGONIUMS.

THERE are a great many ways of propagating these. The Cape varieties may be propagated by means of roots, as may also some of the fancy kinds. Another plan is to propagate by means of buds. In that case, a vigorous shoot is split down the centre; every bud has about half-an-inch of the stem left below it, from which roots will proceed. These will grow if placed in shallow pans filled with loam and sand, and set in heat. Pelargoniums are, however, readily propagated by means of cuttings taken off from the middle of May to the beginning of September. These may be struck in the open ground without any trouble except that of watering them once, as soon as the cuttings are planted, in order to settle them firmly in the soil. They require no shading, and will be well rooted in about six weeks from the time they were inserted, and can be either taken up and potted, or left until August or September, when they must be potted off for the winter in rather poor soil, which will check growth, and cause them to go to rest for the winter. In potting, use plenty of crocks for drainage, as too much water in winter will cause many of the plants to rot. Plants propagated in this way are much stronger and better than those raised under glass. Hundreds of cuttings can be taken from Pelargoniums during the summer months; they should be about 4 inches long, and firm at the base. Let each have a heel if possible, which should be smoothed off with a sharp knife; cut off three or four of the bottom leaves, and put in the cuttings at once, before they dry, in any fully exposed ground that is available—a border facing the west being perhaps best. They may be put in in rows 6 inches

apart, and 4 inches from cutting to cutting. I have seen flower beds in which Pelargonium cuttings, pricked in all round, had a very beautiful appearance in August and September. Every cutting will grow and flower abundantly, and such small-flowering plants have a very pretty effect. If the weather happens to be very dry, a little water may be given for the first few days, and after that they may be left alone until rooted, which will happen soon enough to enable you to pot them off by the end of September, and have a good stock for bedding next summer, or for pot-culture. If these young plants are not allowed to bloom during the time they were making their roots, most of them will bloom during the winter in a moderately heated greenhouse. In taking up bedding Pelargoniums, remember that every old plant is worth a dozen young ones. Old plants with stems of stout well-ripened wood, make excellent specimens that bloom early; in fact, Pelargoniums improve with age, if thinned and properly treated. The Pelargonium does not require a very rich soil—manure, indeed,

does it little good, though some few dwarf-growing sorts require a richer soil than others to bring the blooms to perfection, and in the culture of large specimen plants, manure-water is of much value. For ordinary culture, however, there is nothing like well-rotted sods, or sound loam with a slight admixture of sand. A good compost can be made of sods from an old pasture, which should be piled up in a heap and exposed to the atmosphere, and it should be chopped and turned every three months, until it is about twelve months old. At the last turning, or just previous to its being used for potting, a little sharp sand should be intermixed with it. The process of potting specimens that have flowered must be conducted with care, and should be accomplished when the young shoots have made an inch or so of growth. Then turn out the ball and shake away as much soil as possible from the roots. The roots should then be pruned just sufficiently to enable them to be accommodated in pots two sizes smaller than those in which they flowered. In these pot them firmly, water them well, place them in a cold pit, and keep them close for a week at least; then give air gradually, and at last expose them freely, but

Dictyogramma japonica variegata.

not to heavy rains or frosts. The successive pottings must be regulated by the state of the plants. Those potted at the end of July should be finally shifted at the end of October, and should be allowed to push for bloom during the winter in order to make a brilliant spring display; but the later sorts, potted in July and August, should be shifted on till November, and be put into blooming pots about the end of January, or not till February or March if they bloom late, or prove backward in growth. The main point to be aimed at is, to have plants to bloom in succession, and these several pottings will always effect this. In order to keep the plants in health and vigour, give them room in the house; let there be a free circulation of air, summer and winter, and an average temperature of 45° during the latter season, with a rise to 50° or 55° during sunshine, or when a brisk fire is made up to drive away damp and secure a thorough change of air. I would recommend amateurs to turn their attention a little more to the uses of Zonal and nosegay Pelargoniums for greenhouse decoration; the

value of these plants is not so well known as it ought to be, many having but little conception of the beautiful shades of colour that exist among them. These plants are extremely useful for winter decoration, and possess great powers of continuous blooming. In fact, no other class of plant will bloom so long at one time without appearing shabby, and no other plants can be cultivated with so little trouble. Only a small greenhouse is needed, and no great expenditure in the way of fuel is necessary; they merely want protection from frost, with good soil, water, and plenty of light. There will be no trouble with greenfly, red spider, thrips, or scale. The best varieties are Ferdinand de Lesseps, Ianthe, Jean Sisley, H. M. Stanley, Cremorne, Florence Fraser, Harry Burley, Zenobia, Payne's Perpetual, Tyersall Rival, Rose of Allandale, Sir Charles Napier, Madame Hoste, Marginatum, Alice Spencer, Lucy, Bella, Mrs. Lowe, Mrs. F. Fytche, Matilda and Master Christine, Lord Macaulay, Jessica, La Vivandière, Corsair, Lady Belper, Mrs. Musters, Nelson, Richard Cœur de Lion, Wellington, Mr. Gladstone, Polly, and King. A great many more varieties could be added, but they would not improve the list, which includes those I have grown, and can safely recommend.

HENRY TAYLOR.

AURICULAS, OLD AND NEW.

THERE is one thing remarkable about Auriculas, and that is, that the old sorts grown nearly fifty years ago are still the best flowers, with but few exceptions. On comparing a list of the premier flowers exhibited this year at Manchester with another given in an old horticultural journal for the year 1834, I find that the best flowers of that year are to be found high in the list referred to. Taking green-edged flowers first, Colonel Taylor (Leigh) and Freedom (Booth) had the highest marks in 1834, and they are still the best green-edged flowers; indeed, Colonel Taylor had the premier prize as the best green edge, the other day, in the show at Manchester. Grey-edged flowers have been much improved since 1834; none of the old flowers approach George Lightbody (Headly) or Richard Headly (Lightbody), two grand flowers which are now becoming common; and Alexander Meiklejohn, a new grey-edge, apparently a seedling between Conqueror of Europe and George Lightbody, is also a magnificent flower, and one which took the premier prize at Manchester as the best flower in the show. Privateer (Grimes), Ringleader (Kenyon), Complete (Sykes), &c., are still shown in the prize collections, and they held the highest positions in 1834. In that year the flower that obtained the highest number of marks in the white-edged class was Glory (Taylor), and this is still one of the best. Pillar of Beauty (Hughes) was the second-best white-edge. In selfs there has been much improvement; still the self that took the premier position at the National Auricula Show, Othello (Netherwood), was a popular flower in 1834. The highest on the list in that year was Flora's Flag (Grimes), the second-best being Metropolitan (Redmain). Now, on looking over the lists of other florists' flowers, such as Pinks, Carnations, Pelargoniums, or Dahlias—the Dahlia, by the way, was at the height of its popularity in that year—I find that not one of the flowers are now in the lists. It is not to be supposed that these old Auriculas are more easily to be obtained than the new sorts; in fact, they are more difficult, and not to be bought in the country. The following is a list of the best varieties, new and old:

GREEN-EDGED.

Admiral Napier (Campbell).
Apollo (Beeston).
Duke of Wellington (Dickson).
Freedom (Booth).
Champion (Page), very rare.
General Neil (Traill).
Alderman Wisbey (Headly).
Lady Richardson (Gairns).
Lycurgus (Smith).
Prince of Greens (Traill), new and rare.
Prince of Wales (Ashton).
Colonel Taylor (Leigh).

GREY-EDGED.

Colonel Champneys (Turner).
Conqueror of Europe (Waterhouse).
General Bolivar (Smith).
George Lightbody (Headly).
Alexander Meiklejohn (Kay).
George Levick (Walker).
Miss Giddings (Read).
Ne Plus Ultra (Fletcher).
Richard Headly (Lightbody).
Ringleader (Kenyon).
Robert Traill (Lightbody).
Lancashire Hero (Lancashire).
Alderman C. Brown (Headly).
Unique (Dickson).
Unique (Maclean).
Mary Ann (Fletcher).
Maria (Chapman).

WHITE-EDGED.

Catharina (Summerscales).
Glory (Taylor).
Smiling Beauty (Heap).
Favourite (Taylor).
John Waterson (Cunningham).
Model (Gairns).
Ne Plus Ultra (Smith).
True Briton (Hepworth).
Countess of Wilton (Chatham).
Omega (Turner).
Arabella (Headly).
Bright Venus (Lee).

SELFS.

Blackbird (Spalding).
Crown Prince (Turner).
Charles J. Perry (Turner).
Eliza (Sims).
Formosa (Smith).
Othello (Netherwood).
Lord Clyde (Lightbody).
Master Hole (Turner).
Mrs. Smith (Smith).
Mrs. Sturrock (Martin).
Vulcan (Sims).
Petronella (Headly).
Pizarro (Campbell).
Metropolitan (Spalding).
Topsy (Kay).
Lord Lorne (Campbell).

This list contains nearly all the best flowers that have been

exhibited this year. I finished potting this year on the 18th of May. The drainage becomes choked, and the rich surface-dressing applied in February becomes sour, and it is as well, therefore, to turn the plants out of the pots, and to re-pot as soon as possible after the blooming time is over. The compost used is not rich: a fourth-part of rotted manure, and a sufficient quantity of leaf mould and sand is added to the turfy loam to keep it open. Thorough drainage is essential. I find that if any of the plants become waterlogged they soon show it. Ventilation is the point next in importance; give all the air possible at all times, from now until October; remove the lights from the frames night and day, except when it rains. A gentle shower will do no harm to the green-leaved sorts, but it splashes the meal on the foliage of those that have white leaves. Propagation is slow work in the case of some of the varieties; others increase rapidly. When in Scotland last year, Mr. Meiklejohn, one of the largest growers, showed me a plant of Alexander (Stretch) that had not thrown an offset for six years; it had a long stem, and showed buds where the leaves had decayed. Now, in a case of this kind cut the head off, and pot it in a small pot in some light material; do not water it for twenty-four hours. Place a bell-glass over it closely for a few days at first, afterwards tilt the glass a little, and with care this top will soon throw out roots, while the old stump will also speedily show signs of life, and many cuttings will be obtained from it. As to cleanliness, green-fly is a serious pest, and must not be allowed on any of the plants. Remove it with a small brush, or by fumigating. J. DOUGLAS, in "Florist."

A PLUMOSE CYCAD.

(MACROZAMIA PLUMOSA.)

THIS is one of the most graceful of all Cycadaceous plants for general decorative purposes, its green feathery leafage possessing all the freshness and beauty that belong to the most elegant of Ferns, combined with the permanence and stately aspect of some of our Palms. This fine Cycad grows well in a moderately warm greenhouse or conservatory, where, intermixed with other plants, it will prove to be of the utmost service. It has been recently imported from Queensland by Mr. William Bull, to whom we are indebted for the illustration of it which appears on p. 483. From a small ovate stem, the scales of which are woolly, rise the erect spirally-twisted leaves, which are from 2 to 2½ feet long, and have a flattened petiole. These leaves are furnished nearly to the base with narrow linear leaflets, which are set at intervals of about a quarter of an inch, and are from 6 to 8 inches long. The plant is remarkable for its distinct and elegant character. It has been awarded a first-class certificate by the Royal Horticultural Society.

GLAZED POTS THE BEST.

THE green slimy coating which so very quickly forms on the outsides of pots, in moist warm stoves especially, has long been felt to be an unsightly nuisance in well-ordered gardens. It entails much unproductive labour in plant culture. This is more especially the case where soft, river, or lake water is used, and this is the best kind of water for plants. The amount of rubbing and scrubbing required to keep pots clean is very great, for no one with an eye to order and cleanliness can long tolerate pots coated with slimy green. To prevent this troublesome form of vegetation from growing on the outsides of pots, two years ago we had a quantity of pots glazed outside—every part of them exposed to the eye—all the outside and about an inch of the inside from the top—thus leaving the portion of the pot in contact with the soil and roots just like ordinary pots. So far as greening is concerned it has been a perfect success; and, the colour being a quiet brown, the pots are more unobtrusive and pleasing in appearance than ordinary pots when clean. It is our intention to extend the system to all pots in moist houses at least. It saves an immense amount of labour, and we never had any doubt as to its effects on the cultivation. The common idea of air getting at the roots or soil through the sides of an ordinary garden pot, even when clean, to say nothing of when its pores are filled up with green slime, is not to our mind an appreciable point in practice. Besides, it may be accepted that sufficient air penetrates the ball up through the drainage and from the surface of the soil; and it is not, as a rule, the order of Nature that air gets to the roots or food of plants from a lateral direction. As to the stoppage of evaporation from the sides of pots, we look upon that in moist stove plants as certainly a small evil, generally speaking; and in the case of many plants it is a positive advantage. Rapid evaporation cannot in very many cases be regarded as a gain. The glazing of ordinary pots thus increases their cost about a third, but

they are more durable; and if any other cheaper process could be invented in order to keep pots clean it would be a great point gained in appearance and cleanliness. We have experimented by dressing the outside of pots with silicate and calcium, and the result has proved a failure; though the pots so dressed kept longer clean, they ultimately became green. It will be in the recollection of many that Mr. Beck, of Isleworth, many years ago was a successful prize taker at the London shows with *Pelargoniums* grown in small slate tubs. And those who have visited the Kibble conservatory in the Glasgow Botanic Gardens will have noticed how well tree-Ferns, &c., thrive in galvanised iron tubs, which are very light and, of course, very durable.—“The Gardener.”

TWO-SPATHED FLAMINGO PLANT.

THE annexed illustration is a good representation of this singular monstrosity, of the history of which I can give but little or no information. It was detected on one of a pair of seedlings purchased by me a year or two ago from Messrs. Veitch, and is interesting, owing to its being the first double-spathed form, as far as I can learn, in which the second spathe overlaps the other, the sport known and exhibited some years ago under the name of *Anthurium Scherzerianum Daviesi* having the second spathe at the other side of the stem, and altogether distinct from the ordinary spathe. This

Two-spathed Anthurium.

did not, I believe, prove constant, but reverted to the common variety. I only hope my plant will again produce a similar double-spathed flower next season.

W. E. GUMBLETON.

Belgrove, Queenstown.

Orchids in Bloom at Kew.—The following Orchids, rarely met with in private collections, are now in flower at Kew, viz:—*Arethusa bulbosa*, so beautiful a plant that one could wish it was more plentiful; its solitary nodding flowers are borne on slender scapes, 3 or 4 inches in height. The sepals and petals are of a bright amethyst-purple, and closely resemble the same organs in the old *Bletia verecunda*, while the lip reminds one of that of *Pleione lagenaria*, being slightly convolute, and having three-fringed lamellæ down its centre, while the sides are streaked with amethyst-purple. *Bletia verecunda* (B. Shepherdii) is now flowering freely in the same establishment, its bright purple flowers being borne on great branched spikes or panicles fully 4 feet in length. This plant is well worth growing for cut bloom, as the flowers last fresh a long time. Several plants of the white-lipped *Oncidium pulchellum* are blooming freely, as is also a small specimen of *O. andigenum*, a plant nearly related to *O. cucullatum*, the chief difference being that the ground colour of the flowers, which are purple spotted, is yellow instead of white, tinged with rose. A plant of *Bifrenaria aurantiaca* bears two spikes of bright yellow flowers, barred with rich brown, and is both distinct and ornamental.—B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Seemann's Adiantum (A. Seemannii).—This noble Maiden-hair Fern has pinnae from 3 to 4 inches in length and more than 2 inches in width, borne on fronds about 2 feet long. It has been introduced by Messrs. Veitch, and deserves a place in every stove in which Ferns are grown.—B.

Acanthoriza Warscewiczii.—This is a rare and beautiful Palm from Costa Rica. The leaves are divided into two, three, or more segments, each segment being elegantly curved inwards, giving it the form of an inverted keel, furrowed at regular intervals with less conspicuous furrows between the deeper ones; above, the leaves are a bright glaucous green; below (by which the beauty of the plant is greatly enhanced), they are covered with a silvery down.—Q.

THE FLOWER GARDEN.

WALLFLOWERS.

MR. SHIRLEY HIBBERD gives some good advice about Wallflowers, in the “Gardeners’ Magazine.” “That Wallflowers,” he says, “should abound in beds and borders; on walls and ruins; in the reserve ground, and in the front lines of the kitchen garden, is of course most proper; but just come with me for one moment, and I will show you a place for Wallflowers which usually produces nothing at all, although if it were a Wallflower garden properly so-called the produce of the flowers sent to market would every year pay all the rent. We will first go amongst the plant-houses, and observe that many of them have brick walls of from 3 to 5 feet high that nourish nothing at all on the outside, and might be declared incapable of any out-door service by such as suppose it impossible to grow good plants in hard gravel. The finest Tomatoes have been grown here in a hard gravel walk, the roots having to search for their food amongst the stones and broken bricks and tiles of which the substratum of the walk consists. Let it be understood, then, that all these unoccupied walls rising out of hard walks are just the places for the very best of the Wallflowers, and especially for the old Double Yellow, which in a few years will, in such a soil and situation, rise to a height of 3 or 4 feet, and make a splendid return in the way of cut flowers from Candlemas to Midsummer Day, according to the season. They should not be nailed to the wall, but must be planted in the gravel, with a good soil to give them a start, at from 6 to 9 inches from the wall, and for ever after must take care of themselves, unless they grow inconveniently large, in which case the pruning knife provides some slight remedy. Every aspect, due north and bleak east inclusive, will suit Wallflowers. A further search in the same spirit will reveal bits of gravelly starving waste here, there, everywhere, and they may be all clothed with Wallflowers, if not overhung with trees or excessively damp in winter. The greatest cold ever experienced in Britain will not hurt the Wallflower, but damp, heavy shade, very rich soil, and a close atmosphere are its worst enemies; hence, although it may thrive at the foot of a wall, it would, if it could speak, ask to be planted on the top of it, for the song of the Wallflower is ‘Excelsior.’ In visiting gardens, one sees many failures as well as successes with this useful plant. It is a matter of the utmost importance to secure good seed, but the next thing to do is to manage it properly. I repent me that I did not pen these notes earlier, for it is my rule to sow Wallflower seed some time before the 15th of May, and I find that those I have of late been rejoicing over were sown on the 29th of April. This is a cold soil and a damp locality, and all herbaceous plants that have to stand the winter require careful management, or they disappear. On the chalk and on dry sandy soils anywhere, the seed may be sown any time in May or the early part of June, but I should say that Midsummer Day is the latest moment allowable; for, if they do not make a good growth and become well hardened before winter they will not flower freely in the spring. Our rule is to sow a few rows in the kitchen garden, and, as soon as the plants are large enough to handle, we transplant them into rows a foot apart and the plants a span apart in the row. By the middle of October they are stout and shrubby, and they are then lifted with good balls and put into their flowering quarters, where they become well established before the winter compels them to rest. It is not at all necessary to raise a stock every year, for the plants live any number of years if left alone; but, for bedding purposes, an annual supply is necessary, and the best thing one can do when they have done flowering is to throw them away. To let them stand in the beds is, we will say, out of the question, and to transplant them does not pay, because they want nursing at a time when there is more work than can be properly got through, and our best course is to reduce it by any legitimate means. Now, by raising a crop of Wallflowers from seed every year we reduce to a minimum this part of the work, and have the best show at the cheapest rate. But wherever the plants can be allowed to remain several years, and they are really good to begin with, they should no longer be regarded as annuals, or even as herbaceous plants. They then become flowering shrubs, and acquire a position of the highest importance in the garden. As to the sort of Wallflowers, that is another and a more important matter. Not many of our amateur gardeners are aware of the fine strains of Wallflower that are obtainable. If a particularly interesting example of the improbability of plants is wanted, we cannot do better than direct attention to the Wallflowers; for between the wild plant on the castle wall and the large-flowered variety of the garden wherein Wallflowers are a speciality, the difference is immense. It is a fact of considerable importance that there are many bad sorts of Wallflowers to be found in gardens, as there are also some remarkably good ones. I saw a short time ago, in the garden of my friend, Mr. Crute, Sutton, Surrey, a wall crowned with the most perfect examples of blood-coloured Wall-

flowers I have even seen, the colour being a deep sanguineous crimson, the flowers large and single, and the plants all one height, averaging from 10 to 12 inches. Such a strain is a treasure, and I can match it with a yellow that is the best of its kind that has ever come under my notice. This is called New Golden Tom Thumb. I know not its origin, but as I had the seed from Mr. Cannell, of Woolwich, I suppose it is obtainable at seed-shops. The plants are all exactly alike, as if turned out of the same mould, and we have not seen one "rogue" in a large piece of them. The average height is 9 inches, the growth compact and bushy, branching freely from the base, but making twigs rather than branches. The flower-buds have a most distinct character, being pale green, and inclining to whitish; the flowers are large, smooth, of a rich full, but soft orange-yellow, and the leafage is a brilliant grass-green without the slightest trace of any glaucousness. For all ordinary bedding purposes this, I take it, is the best Wallflower. We have also what we suppose to be a good strain of Belvoir Castle, dwarf yellow, but it lacks uniformity. The best of the plants are of dwarf bushy habit, with smallish leaves, which show a slightly glaucous gleam; the flower-buds are just tipped with brown; the flowers are produced in profusion, and the typical colour is clear canary-yellow, but a few come with streaks of brick-red, and those that are pure yellow are of two or three shades. As I have seen this same strain at Belvoir, it appeared purer than I have it; but if it were purified to the same extent as Tom Thumb it would be equally valuable, for its clear light yellow tint is as valuable in its way as the rich orange-yellow of its rival. It is commonly believed that it is impossible to raise good double Wallflowers from seed, but that is a mistake. I have had many a batch so thoroughly double and so splendid in colour that if one could but be sure of the seed, there would be no occasion for the rather tedious business of raising the old Double Yellow Wallflower from cuttings. When you have good seed it is as easily managed as Double Stocks, and one great point is to select the plants that are to remain carefully, so as to get rid of the bad colours and the single and semi-double kinds. It may be that a good strain of seed will produce varieties equal to the old Double Yellow, but I should be sorry to throw away that well-tried friend in order to put my trust in seed for the future. The habit of the plant is perfect, it makes a great shrub if encouraged by judicious shifting and pinching and allowed time to grow. To make stock of it a little gentle forcing should be resorted to, and the result will be plenty of soft shoots that will make the best cuttings, that may be struck with ease in a very mild heat. We do it in a more simple way. About the middle of June any number of cuttings may be taken from plants that have not been forced, and these are dibbled into pans of sandy soil, covered with a bell-glass, and put into a Cucumber-house, a green leaf being put over the bell-glass if the Cucumbers do not shade the cuttings effectually.

American Violets.—Of the twenty species of Violets, native to the Atlantic States, I have cultivated four which flourish well in the garden. Three of these have leafy, branching stems; the downy yellow Violet, with dark green leaves (*Viola pubescens*); and large white Violet, sometimes purple beneath (*Viola canadensis*), and the graceful pale blue spurred Violet (*Viola rostrata*). These bloom for a long time, and, if slightly shaded, the flowers are very large. The Hooded Violet (*Viola cucullata*) differs from these in having no branches. It bears each leaf and flower on a long scape rising directly from the root like the stalk of a Tulip. It bears an abundance of dark blue flowers in May and June, which are largest in a moist spot. It will grow anywhere. Its habits are so peculiar that it must be kept away from delicate flowers, for it greedily takes all the room it can get, and the thick, knobby root-stocks ramble over the ground, half in and half out, making, with the luxuriant foliage, a perfect mass of solid vegetable matter. As if this were not enough, after the showy blue flowers are gone, it continues all summer to produce quantities of seed from curious little flowers which grow directly upon the root, and consist only of an immense pistil surrounded by stamens.—"Cultivator."

Humea elegans purpurea.—This is higher coloured than the common variety, so much so that grown in the open air it merges into red in the deepness of its rose colour. Few plants are more graceful than the Humea, indoor or out. The catalogues mostly say they are very fragrant. Well, in so far as that means a powerful odour, pleasant or otherwise, the catalogues are right. Many are extremely fond of, others equally averse to the fragrance of Humeas. They give out little or none unless their leaves or flowers are bruised; if untouched they hardly reveal their proximity by their scent. They should be sown in the March of one year for flowering in the summer of the next. It is a good plan to grow them outdoors throughout the summer months at distances of 2 feet by 6. This for the first year, for final effect 6 or even 10 feet apart will be close

enough. Take up and pot them at the end of September, wintering them in a temperature of 45° to 50°. Shift them, if they are to be grown in pots, into 12-inch pots, using good loam to pot with in January; water freely as soon as growth commences, never in fact allowing them to get dry, and the plants will flower through the later summer and autumn months. For open air purposes plant out at the end of May. Place a stout stick to keep the plants upright, water in dry weather, and they will flower freely and prove highly ornamental from July to October or later. Tall flowering plants are often lifted and carefully potted before winter, and prove most useful for conservatory decoration. Occasionally too, a few plants will miss flowering; and if such are taken up and potted they will make trees the third season, each branch being like a common-sized Humea, and the whole plant like a dozen of the normal type knocked into one.—"Villa Gardener."

Percentage of Good Novelties amongst Seedlings.—The percentage of improved novelties amongst florists' flowers, that is to say, the results of cross-breeding amongst this particular class of plants, is thus stated by a correspondent of the "Gardeners' Magazine":—"Mr. Keynes, of Salisbury, sows every year, and has done for many years past, 30,000 Dahlia seeds, and he has averaged about ten named flowers every year for some twenty years or more, which is a very small percentage—it is one-thirtieth per cent; in this case it would seem that many good flowers must be lost, for 30,000 seedling Dahlias ought to give at least thirty varieties worth naming, or, say, one-tenth per cent. The late Mr. John Salter estimated that seedling Chrysanthemums worth naming averaged one in 2,000 plants, or one-twentieth per cent. Mr. Downie gives 500 Pentstemons or Phloxes to get ten first-rate novelties, this being at the high rate of 2 per cent. In the raising of plants that admit of manipulation, such as Pelargoniums, the rate is still higher, the result, no doubt, of the control the raiser exercises. In the case of Dahlias and Chrysanthemums the raiser has not much control, but he selects the seed-parents and watches over the growth of the seed, and that is control to some extent. There are cases in which the cross-breeder goes direct to his work, and, having in his mind's eye exactly what he wants, ensures it right off; but this is not an everyday business."

White Silene.—This is now in flower with me. Its foliage is small, and the blooms, which rise to a height of 7 inches, are borne on slender stems, and produce a pretty effect. They are five-petalled and serrated. Possibly some of your readers can give me its name.—A. D.

Dianthus High Clere.—This hybrid Dianthus is a useful plant for mixed borders. I have two plants of it now in my border, each of which has about twelve flower-stems, and each stem is crowned with fine trusses of bright rosy-carmine-coloured blossoms.—N. H. P.

Clematis ovata.—This showy-flowered species from Carolina forms a dense bush 2 feet in height, and bears deep blue flowers 3 or 4 inches in diameter. Associated with Vesta or other large white kinds, the different colours would have a striking effect.—B.

Bedding Pansies.—Are cuttings of these better than seedlings, and, if so, when should they be put in? Do seedlings come true to colour, and which are the best varieties of yellow, blue, and white for early spring blooming?—ENQUIRER.

Banksian Roses.—We have here two large plants of the white and yellow Banksian Roses, some 25 feet in height, growing in front of the Orange-house. The white is not so profusely bloomed as the yellow; nevertheless both are objects of exquisite beauty, which must be seen to be appreciated.—R. GILBERT, *Burghley*.

Flowering of an Old Variegated American Aloe.—An Aloe (*Agave americana variegata*), which has been carefully preserved for upwards of ninety years, is now showing bloom, and may be expected to be in full blossom, as near as one can judge, in about a fortnight or three weeks. How can I best protect the flowers so as to keep them in perfection as long as possible?—JAMES HARVEY, *Windhill Lodge, Bishop Stortford*.

Double-flowered Silene pendula.—This, unlike the double Cinerarias, is really worth growing, as its semi-double and double flowers are larger, of a richer colour, and continue in beauty much longer than those of the single kind. Indeed, this plant has in addition the merit of furnishing useful flowers for cutting, as many of the blooms are as double as those of a Pink. Lovers of spring gardening will find this double variety worthy of attention.—D.

Brompton Stocks.—These are very beautiful in borders at this time of the year, but are more abundant in small gardens than in the parterres of the rich. The giant scarlet, however, so massive and withal so fragrant, is worthy of a place in any garden, large or small. Not less beautiful, too, but much rarer, is the Giant White, a grand Stock that, when well grown, will produce marvellous spikes of bloom. I have seen them on plants 3 feet in height, 12 inches in length, and equally fine all round. This year my plants are not so large as I have had them, but I have already put out several hundred to flower next year, and, as these are getting established, I shall look for a grand display.—A. D.

Alyssum saxatile.—As a yellow early summer flowering plant, I know none to equal this, blooming, as it does, from the beginning of April until the end of May, and sometimes longer. Planted 6 inches apart, the heads of bloom meet and form an unbroken line or mass of intense yellow. In order to have it in good condition for next spring, preparation should be made at the present time. The bloomless side shoots, which are produced plentifully at this time, make the best cuttings, needing only to be pulled off and dibbled into growing material in some cool shaded place, either in or out of a frame, keeping them a few inches apart, when they form good plants for transferring to the flower beds in autumn. The beginning or middle of October is a suitable time to place them there, and their position should be near the edge, as they seldom attain a greater height than that of 4 inches.—J. MUIR.

New pyramidal Stock var. Mauve Beauty.—This magnificent novelty is the result of several years' careful selection, and has commanded general admiration for its great beauty. It has a true pyramidal free-branching habit, and forms a dense pyramid of flowers; colour, a lustrous pale mauve; it is a grand variety for exhibition purposes. It can be grown as an intermediate variety, if sown in August and September; and the fine examples of this stock shown at the Royal Horticultural and the Royal Botanic Societies' meetings in March, 1872, were so treated.

BOTH SIDES OF SPRING GARDENING.

The description of the spring flowers at Belvoir (see p. 450) makes us all desirous to possess such treasures; but, unfortunately, there is a dark side to the picture, to which attention is directed by another correspondent (p. 437), whose thoroughly practical exposure of the folly of attempting too much in the way of ornamental gardening will meet with a ready approval from many a gardener, especially where the double system of bedding is practised both in spring and summer. The usual time for bedding out—that is about the middle of May—is one of the busiest seasons of the year, both in pleasure grounds and kitchen and forcing gardens; whilst, at this time, wall trees, if not daily attended to, may be expected to receive permanent injury. Before the system of spring gardening came into fashion, the flower beds were, at planting time, in that condition in which a good kitchen gardener likes to see his seed-beds—moist and friable; but when just cleared from a crop of spring flowers, they are dust-dry and impoverished, and there is scarcely time to manure, dig, and water them, much less to pulverise, or get the soil in good tilth for planting—in fact, nothing short of removing it bodily and substituting for it fresh loam, can supply fitting beds for either *Calceolarias* or *Verbenas*; while, put in as well as the means will allow, they perish by hundreds. It is no wonder that succulents are getting so popular; for, unless a bedding plant will flourish on an ash-heap or house-top, it stands a poor chance in flower beds now-a-days. Some complain of the shortness of the autumn display, but how can it be otherwise, while two crops a year are grown on the same beds? I have seen lovely ribbon borders of Pansies and Daisies just about at their best—in fact, a cloud of blossom—removed to the kitchen garden, to make room for the next occupants. Surely, therefore, it is inconsistent to expect a continuation of bloom in autumn under such circumstances, more especially where the plants used for summer bedding all come into flower at one time. Under natural conditions, plants are continually coming into flower in succession—the Primrose and Wood Violet are succeeded by Wild Hyacinths, Veronicas, &c. For my part, I shall always admire gardens like the beautiful

one at Frogmore House, where the velvety undulating turf is enriched by an occasional bed, here and there, of hardy Azaleas, Kalmias, and Heaths; and where the trees and shrubs are in themselves objects of special attraction, just enough of spring, summer, and autumn flowers being grown to give colour to the scene. Under such conditions, the effect is always pleasing, and the reverse of that presented where bedding-out forms the chief attraction.

Henham.

JAMES GROOM.

The Artificial Bog at Glasnevin.—In this bog one may see many species of plants gathered together from far off districts. *Pinguicula grandiflora* is here in abundance, and quite as much at home as in its native localities. Those acquainted with the common

variety need only to be told that this is larger in all its parts, and well named *grandiflora*. For the information of those who wish to collect it, I will give, as far as I know, the localities in which it has been found:—In Kerry, Kenmare, Lusk, Mangerton, Brandon, and at Killarney it is very common, almost to the exclusion of any other. Interspersed over the bog in great profusion is the beautiful Bird's-eye Primrose (*P. farinosa*); this is a rare plant, and easy to naturalise in such a place as is here provided, for though not absolutely a bog plant, it must at all times have abundance of moisture. *Orchis latifolia* major is growing here in great luxuriance. I would not be surprised if the celebrated *Disa grandiflora* would grow and flower well in this bog; it corresponds as nearly as possible to the description given of its natural habitat, and as the *Disa* is plentiful in the gardens, it might be worth while to risk a plant, with a little protection for the first winter. It would be the more desirable to try the *Disa* when we see the success which has attended the *Sarracenia purpurea*, which has not only stood severe winters in this bog, but is at present in bloom, and, if I mistake not, will ripen seed. There are many other rare plants perfectly naturalised here, but those mentioned are those most worthy of remark at present, being in bloom, and I think I have said enough to cause your

Macrozamia plumosa (see p. 180).

readers when visiting the gardens not to forget the bog; and if they go into it with as much enthusiasm as I did they will have considerable difficulty in getting out of it again.—“Gardener’s Record.”

The Fox-glove, both Wild and Cultivated.—The wild Fox-glove of our hedge-rows is a favourite and pleasing summer flower growing here and there singly, or in clumps by the sides of the lanes, or in the woods; but its decorative qualities are best seen when growing in large masses. Wild Foxgloves seldom differ in colour; rarely is one seen that is not of the common red kind, and if one that is really distinct were found it probably would be torn from its roots and borne away in triumph. Garden varieties are not so circumscribed in this respect. In these the colours vary much, and include pure white, cream, rose, red, deep red, and other shades.

The great charm, however, of the garden varieties lies in pretty throat markings, consisting of spots and blotches of deep purple and maroon, and these, when seen in large flowers, make them resemble those of a *Gloxinia*, hence the name *gloxinioides*, applied to some finely-spotted kinds. The garden plants are more robust, the stems stouter, and the flowers much larger than those of the wild kind, and, altogether, they make at the present time truly grand border flowers. The seed being small, it is best sown in pans or boxes under glass early in May, and when the young plants are well up they should be placed out of doors to get thoroughly hardened before finally planting out. Where planted in shrubbery borders it is well to make clumps of three plants; as they produce a finer effect than when set singly. Not unfrequently the Foxglove blooms two years in succession; but, in all cases, it is well to sow a little seed annually.—ALEX. DEAN, *Bedfont*.

Climbing Roses after Flowering.—Will some of your contributors kindly tell me how to treat the *Maréchal Niel* Rose, now that it has finished flowering? It appears to me to be one requiring special treatment. It has flowered well this year, but the blooms were not so large as they were last year. As it is said that it ought not to be pruned at all, I contented myself with giving it some of Standen's manure, with plenty of clean water, and syringing it. The tree is planted in the border of a house about 20 feet long, and gets no heat in winter. It has nearly covered the roof; but it is getting very naked of shoots towards the bottom, which detracts from its beauty. I find my climbing Roses all apt to do that; but I begrudge cutting them back. I have a fine climbing *Devoniensis*, which is rampant in growth, but has the same fault; the buds appear to be blind. *Maréchal Niel* only flowers once a year with me; but it ought to bloom in the autumn, ought it not?—A. OWEN.

Origin of Polyanthuses.—How these old-fashioned flowers were first raised seems still to be an open question. I have raised some pretty kinds from seeds of our Meadow Cowslip; while, on the other hand, from seeds of the true or large-petaled *Polyanthus* I have raised Cowslips and plants resembling, to some extent, the true *Bardfield Oxlip*, but none of the specimens had even a resemblance of the wild *Primrose* of our hedgerows. I have had many plants in my garden bearing a very close resemblance to the Cowslip, from which I have no doubt they were originally procured. There are also thousands of specimens in cultivation called *Polyanthuses* which are nothing more than the pink variety of the *Primrose*. From the wild *Primrose* I have also raised many pretty varieties, but it is a remarkable fact that, if they are allowed to grow or are neglected, not manured, or frequently transplanted, they quickly revert to the old-fashioned but still favourite *Primrose*.—J. R.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Japanese Primrose in North Wales.—My plants of this out of doors are now magnificent, some of them being 2 feet 8 inches in height. Ought the large old plants to be taken up, divided, and re-planted at the proper time, or ought they to be left undisturbed? They are two years old.—A. O.

Windflowers at Kew.—*Anemone pennsylvanica* is now blooming freely at Kew, each bloom being about the size of a shilling. *A. sylvestris*, or *Snow-drop Windflower*, is also in bloom, and at first sight reminds one of a dwarf form of *A. japonica alba*, but the leaves are much more finely divided.—Q.

Iris reticulata not Flowering.—I have some plants of this that do not flower, and should be glad if any of your readers would tell me the reason, as I am very fond of the plant.—H. P. [Probably the plants require to get stronger. This charming *Iris* flowers freely in warm sandy soils; in fact, we know one garden where it is becoming almost a weed.]

Aubrietia Hendersoni.—Amongst spring-blooming plants, this *Aubrietia* must always occupy a prominent position from its neatness of habit, and the great profusion with which its lovely tinted violet-purple flowers are produced. It is unquestionably the most effective variety of *Aubrietia* that I have grown, and is one of those exceptional plants which cannot fail to please.—G. WESTLAND.

Packing Flowers for Travelling.—I was present lately at the opening of a box of Rose-buds (*Maréchal Niel*) in Covent Garden Market, and noticed that they were packed in short Grass, evidently taken from a mowing machine—the box being quite full. If care be taken that the Grass is neither too dry nor too wet, I believe that many delicate flowers, packed in this way, would travel long journeys in the hottest weather and arrive as fresh as if just cut.—W. T. P.

Viola pedata.—In reply to Mr. Dean's question (see p. 450), allow me to state that *Viola pedata* flowers freely, both introduced plants of it and those obtained from seed. I have seedlings of this *Violet* two years old in flower, and the third year they never fail to bloom well. There is another closely allied Canadian species called *Viola pinnata* sometimes sold for *pedata*, which does not flower, at least I have never seen it do so, although it always bears an abundance of seed-vessels.—T. S. WARE, *Hale Farm Nurseries, Tottenham*.

The Giant Scarlet Poppies.—These noble plants (*Papaver orientale* bracteatum and their varieties) are not at all sufficiently used, considering their magnificent effect in the flower garden or shrubbery when judiciously placed. They are perhaps seen to best advantage on the margin of a low shrubbery. They push up boldly among the shrubs, and with their great bright flowers light up the garden in a splendid manner. Another point in their favour is that they will grow without attention in any soil, and their foliage is somewhat Fern-like and graceful.—A. DAWSON, *The Cedars, Chiswick*.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Planting Celery, Sowing Peas, Endive, &c.—The main crop of Celery should now be planted, choosing showery weather for this operation, should such occur within reasonable time, as when the ground is moist and the weather dull the roots lay hold of the new soil more quickly than they could be induced to do by artificial watering. The last sowing of Peas may now be made where these are required as late as they can be had; but, unless in open favourable situations, the produce of such late sowings is precarious. Give them, as previously advised, plenty of room, by sowing thinly and having the rows placed far apart. Where Endive is required early, a little of the *Green Curled* variety may now be sown; but, as this early-sown crop is liable to run to seed, it is not well to have too much of it. Where Broad Beans grow strongly when they come into flower, they will be benefited by having their tops nipped off. This has the effect of concentrating the efforts of the plants to form pods instead of making useless growth.

Planting Broccoli.—Winter and spring Broccoli should now be planted, and if the plants have been treated as advised some time ago, they will now be fit for putting out. In the case of Broccoli, it often happens that with only a moderate frost great quantities of it perish. Except in extremely low damp localities, this is more attributable to the way in which the crop has been treated than to the kinds grown being tender or the situation at fault. In order to impart to the Broccoli that hardy condition of growth which is indispensable to its standing a severe winter, it should be planted widely apart; if planted too close, it is certain to be weak and soft, and almost sure to succumb on the first occurrence of severe weather. If the land on which it is to be grown is of average quality and fairly manured, the plants should stand a yard apart each way. Where ground is limited, this may seem extravagant, but it is false economy to run the chance of losing the greater portion of the crop through an attempt to grow more than the space at command will permit. On poor inferior soils, where the plants will not attain full size, they may stand 2½ feet apart.

Fruit.—Should the weather keep dry, Strawberries on light shallow soils will require water. This fruit succeeds best on heavy lands, and amateurs are often baffled in their attempts to grow it where the soil is of an opposite character. Under such circumstances, a plentiful supply of water, not only at the time when the fruit is swelling, but after it is gathered, is essential to the well-being of the plants, in order to enable them to make good growth, and produce large plump crowns for another year. Continue to remove all Raspberry suckers that make their appearance round the base of the plants, retaining only sufficient shoots for next year's crop. These may vary from four to eight, according to the strength of the plants. By removing all superfluous shoots those that remain will be much stronger than they otherwise would be, and in a better condition to produce heavy crops than when all the shoots that make their appearance are allowed to remain for no other purpose than to be cut away at pruning time. In gathering Gooseberries and Currants for bottling and similar purposes, a portion should be taken from each tree, instead of, as is often done, stripping the whole from some bushes and leaving others to carry all that have set. Thinning hardy fruits does not receive that attention from us that it does in France and in the Channel Islands. With us the cost of labour has doubtless much to do with this matter, especially where large breadths are grown; but, with the limited number of trees cultivated by amateurs, there is no excuse for such neglect. Apples, and in some places Plums, this season have set in such enormous quantities that, unless reduced by timely thinning, they never can possibly come to perfection. Some Plums, as *Victoria*, for instance, will set in great quantities, and remain until after the stoning process is complete, but, before ripening commences, they will fall off in such numbers, as to literally cover the ground. Ere this takes place they will, however, have so exhausted the trees as to leave them unable to swell off those that remain at anything like the size which they ought to attain, and in such cases the quality always suffers in proportion. Apples should in like manner be thinned; in the case of culinary varieties, where the trees are not so excessively laden, a good deal of the necessary thinning may be done by removing for use a portion of the crop as soon as the fruit is large enough, but under no circumstances leave a superfluous quantity too long on the trees. Dessert kinds where they are too thick should be thinned as soon as they have formed their pips. When this process is complete they will show what portion of the fruit will fall of their own accord. Pears, where still too thick, after they have cast off such as fall naturally, should in like manner be thinned.

Chrysanthemums.—These indispensable autumn flowering plants should be at once transferred to their flowering pots, the most suitable sizes of which are those of 10 or 12 inches in diameter. As

they get large and the soil is filled with roots these plants require great quantities of water; therefore, the pots must be well drained. Grow them in good loam, to which add one-fifth of rotten dung and a little leaf-soil, with sand sufficient to keep the whole porous. Chrysanthemums do not like light potting; therefore, make the soil firm, and do not fill the pots too full or the plants are almost sure to suffer afterwards through the want of space sufficient to hold water enough each time it is applied. With pots of the size advised there should be $1\frac{1}{2}$ inches space betwixt the surface of the soil and the top of the pot. Plunge the plants out of doors in an open place where they will get plenty of sun and air, but, where they will not be so much exposed as to get broken by the wind. The best material for plunging in is coal ashes, but, if these cannot be had ordinary soil will do. Tie each plant out as soon as potted, so as to lay the foundation for the future specimens, and to prevent their being injured by the wind; do not continue longer to stop the shoots. Give sufficient, but not too much water, until the roots have become established.

Primulas, Cinerarias, and Zonal Pelargoniums.—Both Primulas and Cinerarias, if sown as advised, will shortly be fit for placing in thumb pots, in soil consisting of three-fourths good loam and one-fourth rotten dung and leaf soil in equal quantities, with a good sprinkling of sand; when potted, put them into frames facing northwards, as these plants cannot bear exposure to full sunshine, to break the rays of which, when very bright, shade with a piece of netting or thin canvas. Cinerarias should stand on a bed of ashes that will hold moisture and maintain a humid atmosphere about the plants. They cannot endure being placed on shelves exposed to drying currents of air. Place Primulas on inverted pots, so as to keep them up near the glass, or they will become drawn and long in the leaf-stalks. After potting, keep the lights closely shut down at night, with only a little air on during the day until they have commenced to grow freely, after which give air plentifully night and day. Zonal Pelargoniums are useful for winter flowering, but they require to be specially prepared for this purpose. Last autumn-struck cuttings should now be placed in 6-inch pots, in ordinary loam, and at once plunged in coal ashes in an open situation, where they will be fully exposed to the sun. If older plants, that have been cut back, are used for the purpose, they will require a little larger pots, but, on no account, must they have too much root room, as the object is not to get large plants but such as are stout in growth and thoroughly ripened; it is not possible to make them too hard, as in that condition they flower through the winter with a little warmth, instead of running to leaf, as would be the case if they were vigorous and full of growth. Keep all flowers which they throw up during the summer removed as soon as they make their appearance; plants treated in this manner through the summer will bloom freely up to Christmas in the windows of an ordinary room where a fire is kept up, bringing them indoors about the middle of September, after which it is not safe to leave such plants out, as, if only slightly injured by frost, their flowering is interfered with. There are many amateurs who have not much convenience for plant-growing but who like to have their windows gay with flowers, and one of the greatest difficulties with which they have to contend is the destruction of aphides, to which their plants are subject, and which are not easily killed by fumigation where no proper place is at hand to apply it, and where only a few plants happen to be affected, the operation often gets put off until they are half spoilt. In such a case as this, the most simple and convenient remedy is to get an ounce or two of common Scotch snuff, and dust it over the affected plants, for which purpose use a bit of fine gauze, formed in the shape of a small bag; if this is found to be too open, use the gauze double, and, in applying the snuff, lay the plants down on their sides over a newspaper—by this means there will be no waste, the paper catching all that does not stick to the leaves. There is one thing to be observed in this as in all other methods of destroying insects on plants, and that is the snuff must be applied in such a way as to reach every affected shoot and leaf, otherwise the destruction will only be partial. Allow it to remain on for a few days, after which the plants may be again laid on their sides, and the snuff washed off by syringing with clean water.

Vineries and Peach-houses.—Continue to treat Vines in their several stages of growth as advised in previous calendars; look well to the foliage being free from red spider, as upon this, to a considerable extent, will depend the condition of the fruit when ripe, and also the state of the wood for next year's crop, as, next to over-cropping, nothing tends to weaken the constitution of the Vine so much as allowing its foliage to suffer through the ravages of red spider. If the use of the syringe has been continued daily, as recommended some time back, there is not much danger of this pest being troublesome; if, on the other hand, little water has been thus applied, it may now be expected to make its appearance. When

discovered, the affected leaves should be carefully sponged with clean water, on both upper and under surfaces, in addition to a subsequent thorough syringing. Allow Peaches to be fully exposed by removing all leaves that shade them. Syringe the trees daily, in order to keep the foliage clean.

Indoor Fruit Department.

Vines.—Encourage free growth in the case of all young Vines planted out this season, by closing the ventilators early in the afternoon, so that the temperature may remain about 90° for an hour or two at that time. Damp all bare surfaces, and use the syringe freely where the slightest indication of the presence of insects can be detected. Do not let the growths on one-year-old spring-planted canes become crowded, which they are apt to do about this time. The leading rods, which may have been allowed to grow to make a quantity of foliage for forming roots, should never be permitted to come nearer than a foot of each other, and the lateral growths produced on these must be kept in to the first leaf. Where only one or two canes have been taken from each root, the secondary growths may be left longer, their length being regulated by the space there is around them. Vines planted last season and brought into growth early without forcing will now be getting well established. Bunches will be appearing on the strongest rods, and the number left on must depend on the capabilities of the Vine. Some may be allowed to bear two, and others four and five, but it is always best to crop lightly when at this age, or the Vines will be liable to become prematurely impaired in health; no bunch should be left on the leading shoot, the great object being to get that as perfect as possible for next year's supply. Those who have plenty of Grapes on older Vines will lose nothing by not fruiting young Vines of this age till next season; but temporary ones, planted along with them, may be cropped heavily, as some of them may have to be dispensed with next spring. Those planted two years ago should produce some fine Grapes this season. The size of the bunch and strength of the Vine should determine the weight. When well regulated, a bunch on every alternate shoot on the lower portion of the rod is an average crop for ordinary Vines.

Pines.—Successional plants, intended to furnish supplies about October and November, should now be showing fruit; with mid-summer light and air, little difficulty need be experienced in bringing the fruit well and rapidly up when it is formed, but bottom-heat must not be neglected, as, even at this time, it is of great advantage to the healthy condition of the young fruit. With a little attention, the desired bottom-heat may be derived from the plunging material alone. If the fruiting plants are amongst others not so far advanced, those showing fruit should be taken out and plunged in a bed by themselves; but, before doing this, work in some new plunging material, and a little fire-heat for a night or two will start a bottom-heat sufficient to keep about 85° for a long time. When they are not re-plunged, the material, which may have subsided, should be watered and firmly well pressed up to and around each pot.—J. MUIR.

Peaches.—To prevent ripe fruit falling to the ground and getting spoilt a good plan is to suspend a herring-net under the trees in a series of founces or doubles so as catch the falling fruits and yet not allow them to fall too far and perhaps knock against each other, as they would do if all fell into one part of the net. Succession-houses may be kept closer and warmer than those in which the fruit is ripening and syringed more liberally. Houses in which the fruit is stoning should be carefully attended to during bright hot weather, giving abundance of ventilation early; a slight shade would also benefit the trees at mid-day during hot weather. At this stage, at which an overstrain would have the tendency to cause the fruit to drop, see to the final thinning of the fruit in orchard-houses, and take care that the borders are abundantly moist as a precaution against red spider and blight; for, sure enough, those enemies will at once attack a tree in distress. The crop must also suffer if the roots be dry, and if the fruit gets stunted from dryness now no after management will bring it up to the required standard. The front ventilators may be kept open day and night when the wind is south or south-west.—W. D. C.

Flower Garden and Pleasure Ground.

The greatest possible order is now indispensable in this department, and the growth of the various climbing plants used for covering wire-work of any kind, walls, pillars, or arches, must therefore be frequently regulated. Stake and tie up tall-growing plants, and peg down such trailers as the various kinds of Verbena and Petunia. In geometrical flower gardens the height and habit of the plants used should be well considered, as this is quite as necessary as is the proper arrangement of the various shades of colour; therefore every effort should be made to keep all lines well defined and even in height; while, the judicious disposal of standard plants, or single specimens grown in any desired form, will have the effect of pre-

venting anything like monotony. Let all such plants be carefully and neatly staked; for, if this operation is unskilfully performed, a bad effect will be produced. Beds and borders planted in the carpet style will require unremitting attention, as regards regulating the growth of the plants employed in that way; strong shoots must be stopped and pinched back, in order that the surface of the beds may be covered as soon as possible; and care must at the same time be taken to preserve the pattern or plan of the beds, the divisional or marginal lines of which are generally formed by some of the most compact-growing succulents, such as the *Echeveria secunda glauca*, *Sempervivum californicum*, &c.; while the various shades of colour required to fill in and complete the pattern, are furnished by such plants as the various species of the high-coloured *Alternantheras*, the Golden-Feather *Pyrethrum*, or *Stellaria graminea aurea*. The latter appears to be an exceedingly useful plant for this style of gardening; but for small beds it will probably be found to be less manageable than the *Pyrethrum*, and the shade of colour is the same, or nearly so. For the production of neutral tints, the various *Sedums* will be found useful; and if it be considered desirable to use flowering plants at all in carrying out this style of planting, the most useful for the purpose will be found among the dwarf *Lobelias* of the pumila section. Since we have had the benefit of some refreshing falls of rain, annual flowers of all kinds have made considerable progress, and will require thinning out wherever they are found to be too thick upon the ground. As has been formerly stated, a flower garden, furnished or planted chiefly with a good selection of these plants, need be little, if at all, less interesting than others where ordinary bedding plants are alone used. Various kinds of deciduous shrubs will now be out of bloom, and should be cut back when it appears necessary. Hedges, formed of the tree Box, and of Privet, or other free-growing plants, will require clipping at this time; and, to keep such hedges in good order, it is necessary to perform this operation twice, or even three times, during the season.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

The May-bug and cockchaffer are very plentiful in some localities this season, and often do great damage to Roses coming into flower; for they eat all the tops off the petals of the flowers as they open. They lurk under the foliage or in the centre of an open Rose during the day-time; and, by carefully looking over the plants, a great many may be destroyed. They are amongst the most destructive garden pests that exist. The grub lives in the ground, feeding on the roots long before transformation takes place. Also see to picking off all caterpillars. Aphides can be washed off by means of forcible applications of the syringe, and the use of Quassia-water. All who intend to exhibit cut Roses should go over their plants, and thin out the clusters to one bud every two or three days, so as to get the flowers open at one time, and improve their size by thinning out at intervals. The exhibitor has a better chance of getting the flowers open to the day than by trusting to thinning all flowers at one time. If he requires a stand consisting of, say, twenty-four varieties, he should select about forty of his best Rose-buds to cut them from; thin out the cluster to one bud, and this should always be the top or centre bud of the cluster. By repeating this operation about three days afterwards an even collection of flowers may be secured all in perfection at one time. Water freely, as Roses require feeding well if wanted for exhibition purposes. For outdoor Roses stable manure-water is as good as any that can be used. If the days are very hot and the sun's rays powerful it is advisable to use paper shades or the edges of the petals will be destroyed, and the Rose will thus be damaged for exhibition. Pot Roses out-of-doors will be found, in many cases, to be slightly attacked by mildew, which should be at once stopped by sulphur or Ewing's mildew destroyer.—H. G.

The Wild Goose Plum.—It is a curious fact that in America, where our European Plums are, for the most part, killed by the Curculio and the borer, this kind is said to escape. Its great value consists in its early maturity; it ripens from the 17th to 25th of July, a time when most markets are almost without a supply of fresh and attractive fruits. Secondly, it is of good size, form, and colour, being of the brightest light crimson, $1\frac{1}{2}$ inch long by 1 inch deep. Thirdly, the excellent quality of its fruit for eating, sauce, and preserving, is remarkable. It can be taken from the tree as soon as it begins to colour, while still hard, packed, and shipped to distant markets; it ripens perfectly while on the way, and will keep for some time after it is fully ripe. The tree is vigorous in growth, highly ornamental, and easily propagated, and when budded on the Peach, on which it grows perfectly, does not throw up suckers, and has no objectionable features.

THE GARDEN OF THE ELYSEES.

A TYPE of a large class of Parisian private gardens is that of the palace now occupied by Marshal McMahon. The too frequently accepted notion is that, given a small garden in a city, it should be geometrical in design. This was exemplified in our own stiff and stony Kensington. Frequently persons alluded to the difficulty of treating this garden in any other way. But there are only apparent difficulties in the way, as anyone can see by examining such gardens like that we now illustrate. Here we have streets, high walls, houses, and all the other impediments to good effect in landscape gardening, and yet a quiet fresh charming result is produced. It is always easy by judicious planting, to hide objectionable surroundings, and, both in Paris and London, many deciduous trees attain almost as noble proportions as in their native forests. Then in those French town gardens they have a way of covering objectionable surfaces with a lovely mantle of Irish Ivy, so carefully pinched and tended that in winter or summer the effect is charming. In this way trellises, high railings surmounting walls, gates, &c., are not only rendered inoffensive to the eye, but really made to add to the charms of the garden by the great extent of rich glossy verdure which they support. There are cool shady walks here, too, quite as refreshing in their way as many away from cities, and there is fresh Grass kept green at this season with abundance of water, and there is a pleasant and open lawn—though a small one. The absence of the idea that we should be excessively geometrical accounts for this. Without the little open lawn as a foreground, so to speak, the garden picture would be, to a great extent, lost. It is instructive to compare this picture with one of the old Dutch or other geometrical gardens frequently represented in old engravings, or with some modern English geometrical gardens, sometimes supposed to be "original" in design, but which are simply reproductions from times when people had not half a dozen kinds of evergreens—when simple conventional figures were sufficiently appreciated to be worth delineating on the ground. In these private French gardens it is unusual to have any regular or formal set of beds, and this we think a great improvement. One half the miserable formalities existing in our gardens arise from the presence of a series of formal "figures," or beds, which have to be filled once or twice a year, in the hope of making them look somewhat presentable—a result seldom obtained. Natural or artistic they can never be. If one desires to place some favourite plant in one of these beds, the chances are that it may not be done for fear of violating the unity of character which the whole should possess. A beautiful garden may be made without a set of formal figures of any kind, and by the adoption of one or more types of beds, such as circles and ovals, placed here and there in the spots we desire to embellish with flowers, either singly or in groups. This is the way now common in many recent French gardens. The very common mistake of forming small pools of water near a house exists in French gardens as in our own; and usually the water is stiff in outline, and not by any means an addition to the charms of the garden. The wise landscape gardener will not attempt that which he cannot do well. In a small garden no satisfactory effect can be produced from water, except in the form of a clear rivulet. S.

The Nomenclature of Hardy Plants at Kew.—The nomenclature in the herbaceous department here is capable of improvement, judging from the following from the "Gardeners' Chronicle":—"The bed of Aquilegias evidently needs re-naming, as a dark blue is named *Aquilegia glandulosa alba*; a reddish-peach kind, *A. Whitmanniana alba*; and *A. blanda azurea alba* is the purest white in the whole bed." Anybody acquainted with the garden, and at all familiar with plants, knows that the same kind of neglect is observable in the case of many other families. With the most liberally-endowed and probably the most accomplished botanical staff in connection with any existing establishment, the public have a right to expect more than this. In the herbaceous part of the Garden of Plants, at Paris, every plant is labelled as accurately as in an authoritative work, or in a good herbarium. We may add, that a botanical garden does not fulfil its simplest and most essential object if it does not show us plants properly named. No such errors as the above are evident in many nurseries or private gardens, devoid as these usually are of any trustworthy means of identifying plants.

VIEW IN THE GARDEN OF THE ELYSEES.

THE FRUIT GARDEN.

AMERICAN PEARS.

By C. M. HOVEY.

I WAS much interested and highly pleased with M. Jamin's "List of Pears worth growing," given in your last volume (1874, p. 455), and his general remarks thereon. No one is better able to impart information upon the subject than M. Jamin, and no one has done so more completely. At no fruit-growing establishment in France was I so much gratified as at M. Jamin's, and when there I added many kinds to my collection which he recommended as desirable sorts. Among them was one very fine summer Pear which he does not notice, viz., the St. Menin, or Omar Pasha; this I received from M. Jamin in 1845, and in 1855 I purchased, among other new Pears, the Omar Pasha, which proved to be the same. It is a good sized Pear, very high flavoured, and really excellent, but does not keep long. I consider it much better than any of the August Pears which he names, except Williams's Bon Chrétien, which, with me, is a September Pear. Much has been said in reference to Pears being adapted to particular localities, but though some sorts are fastidious, I am of opinion that the greater part will grow wherever good culture is given them. What has always puzzled us Americans is that Knight's Monarch should still be rated as a fine Pear in England, as, with us, it is worthless, and we see M. Jamin tells the same story. I had supposed, many years ago, that the kind which I cultivated could not be the true one; and in 1844 I selected some trees of it in London, several of which I planted, expecting great results. But from that day to this I have never seen a Pear of it fit to eat, and have grafted over all the trees but one. The only reason that I can see why Knight's Monarch does not succeed with us is that our climate is not cold and damp enough for it. Mr. Knight was unfortunate in selecting the Crassane as the parent of his seedling; had he taken Williams's Bon Chrétien the result might have been different. I was somewhat surprised to find that many of the Pears which we grow sometimes very fine, as standards or dwarfs, require a wall in France. I had the impression that where the European Vine will grow, the Pear would flourish without assistance. Of the several varieties of Pears which M. Jamin specially names, I have found the following excellent here as standards:—July: Summer Doyenné (Doyenné d'Été) and Beurré Giffard. August: Williams's Bon Chrétien (Bartlett). September: Doyenné Boussoch, Beurré Superfin, Beurré Hardy, Louise Bonne of Jersey, and Fondante d'Automne (Belle Lucrative). October: Beurré Bosc, Marie Louise, Beurré d'Anjou, Doyenné du Comice, Beurré Clairgeau, and Duchesse d'Angoulême. November and December: Winter Nelis and Joséphine de Malines. These are all the Pears on M. Jamin's list that I have found profitable or trustworthy for cultivating as standards, for I wish to have it understood that all our trees are standards or dwarf standards. Some of the others grow well enough, but are poor Pears, and some of them can only be grown in favoured localities, under high culture; in fact the following have been discarded, and some of them placed by the American Pomological Society among the rejected sorts, viz., Bergamotte d'Été, Beurré Gris, Van Mons, Doyenné Gris, Soldat Laboureur, Bergamotte Crassane, Figue d'Alençon, Orpheline d'Enghien, Beurré d'Hardenpont, St. Germain d'Hiver, Passe Crassane, Bergamotte Fortunée, and Bon Chrétien d'Hiver. Bergamotte Fortunée is thought to be about as good as a Turnip. In California the Easter Beurré and Glou Morceau are fine, and grand Pears they are when grown as California alone can produce them. Now, you may ask, if we reject so many once fine Pears, what we have with which to supply their place? Well, our answer is American Pears, of which we have now over one hundred fine sorts. A few of these appear in English catalogues, but only a few, and I am surprised that they are so little known to your pomologists. To be sure they have nearly all been introduced to notice since 1835, and some of them within ten or twelve years—nearly long enough to get well known, even abroad, though it takes a long period to find the real value of a new Pear. We hardly want a better Pear than Doyenné du Comice, or even Beurré Hardy or Beurré

Superfin. It will be a long time before these are excelled. But what cultivators do want, even if not quite up to this high standard, are kinds that can be relied upon—such as will bear a full and certain crop under ordinary culture, attractive in appearance, excellent in quality, and kinds that will find a ready sale in the market. This is what we have been aiming at; and, when our climate is considered, we have made good progress. I should like to see them fairly proved in England. I will name and briefly describe such as we have found to be of the character just named, premising that I do so after a careful trial of from twenty to thirty years; and as some idea of what that trial has been, I give you the number of kinds of Pears from which we have gathered one or more bushels of fruit each year, and the whole crop for the last ten years:

Year.	Varieties.	Whole crop. Bushels.	Year.	Varieties.	Whole crop. Bushels.
1865 . .	94 . .	711	1870 . .	85 . .	938
1866 . .	101 . .	728	1871 . .	120 . .	1,016
1867 . .	75 . .	531	1872 . .	105 . .	683
1868 . .	70 . .	744	1873 . .	135 . .	1,637
1869 . .	70 . .	594	1874 . .	130 . .	1,154

All the trees were perfect pyramids ten years ago, but have been pruned to 3 or 4 feet, in consequence of the lower limbs obstructing the walks, upon each side of which they are planted, just 6 feet apart, and 3 feet from the edge, the whole making a continuous line, if in one row, over a mile long. At the quarter-centennial of the American Pomological Society, held in Boston, September, 1873, we exhibited 328 varieties, our entire collection exceeding 500.

July and August.

The only Pears which ripen in July in Massachusetts are the old Amiré Johannet and Doyenné d'Été.

Manning's Elizabeth.—This is not, correctly speaking, an American Pear, but an adopted one, as the scions were sent by Van Mons, in 1833, to the late Mr. Manning, with several others, under numbers, Dr. Van Mons requesting Mr. Manning to name them, should any of them prove good. This was the only one of any value. It is a very beautiful and very fine Pear; small, but sugary, melting, and exceedingly rich. It is golden-yellow, and just one-half of the Pear, transversely at the crown end, is of a deep rich crimson, usually edged with a line of russet, and the remainder golden-yellow. It ripens about the 10th or 15th of August. The tree is only a moderate grower, and of somewhat regular yet open habit, but a good bearer.

Brandywine.—A most delicious variety, of good size, shaped like Beurré Giffard, much russeted, possessing a decided vinous and piquant flavour, full of sugary juice. The tree grows even more close than a Lombardy Poplar, with vigorous long branches, and every other year they are weighed down with the crop. One of the very best. Ripens about August 20th, and is a native of Delaware.

Boston.—A very remarkable Pear, coming nearer to the old White Doyenné than any Pear when gathered in proper time and house ripened. If allowed to hang on the tree too long, it becomes mealy. Of good size and Doyenné-shaped. Skin, clear golden-yellow, with a polished waxy surface, and a cheek of pale blush. An enormous bearer every other year. Tree, very vigorous and of good form. This Pear bears upon the tips of the new shoots, and if these are shortened more than half, the crop is lost. Ripe, August 25th, and will keep two weeks.

Bloodgood.—A Pear of decided character, of fine flavour, with a yellow skin, mottled and traced with russet. Ripens August 25th. The tree is a slow grower, of fine habit, and a heavy bearer.

Moyamensing.—A summer Pear of much excellence, in the old Doyenné style, every Pear having a slight suture on one side like a Peach. It has a smooth yellowish-green skin, very melting, but does not keep long. The tree is moderately vigorous, erect, and productive, the fruit ripening August 20th.

Clapp's Favourite.—One of our newest Pears, as large or larger than Williams's Bon Chrétien, and ripening from August 25th to September 7th. It combines the qualities of the Flemish Beauty and Williams's Bon Chrétien, and has not the disagreeable musk of the latter. It is very handsome, with a broad deep crimson cheek. It should be gathered

early, and it is not a long keeper; but, for its season, is the largest and among one of the best. Tree, very vigorous, and a good bearer.

Sterling.—Another very handsome Pear of roundish form, good size, with a lemon-yellow skin, and bright red on the sunny side. It is not strictly first-rate, but is better than Citron des Carmes or Bergamotte d'Été. The tree has an open, rather spreading habit, and bears a heavy crop, which will keep two to three weeks.

These may be considered the choicest of our summer Pears, but the following are good:—Deardorn's Seedling, Osband's Summer, Ott, Muskingum, Tyson, Cushing, Julienne, Harvard, &c.

September.

Hanners.—This is an early St. Germain, having all the qualities of that fine old Pear when in perfection. It is of good size, yellowish-green skin, juicy, melting, refreshing, and excellent. It is a vigorous-growing and fine-shaped tree, producing abundantly, but the fruit does not keep long.

Adams.—A fit companion to Williams's Bon Chrétien, but of regular and handsome form, exceedingly beautiful, with a waxy-yellow skin, and fine rosy cheek. It has a rich vinous flavour, very melting, and keeps a long time. The tree is only moderately vigorous, but of a good pyramidal shape, and bears well.

Excelsior.—This fruit has the general appearance of a Bon Chrétien, but is not so large, and has a skin thickly covered with dark points. It is remarkably vinous and rich, and has quite a new and peculiar flavour. Bears in clusters, and is very productive. The tree is irregular, with peculiar Apple-tree-like wood.

Andrews.—This is a Pear that has been known for fifty years, and can be traced back nearly a century, yet is now as perfect as when I first knew it. It is sometimes called the Water Lily Pear, the skin having the delicious fragrance of the flowers of our Nymphæa. It is one of the best September kinds, has an oily skin, rich juice, and a delicate aroma. It succeeds the Bartlett (Williams's Bon Chrétien). The tree is a very slow grower, in consequence of its great productiveness, and the fruit keeps well.

Moore's.—This is a fine Pear, and would stand very high but for its habit of falling from the tree, and its liability to be worm eaten. Why every fifth Pear should be wormy, when other Pears growing next to it should be perfectly free is a curious fact. Probably these pests select the best. It ripens in succession up to October 15. Very large, very beautiful, and very excellent. Twelve perfect specimens make the most attractive dish of Pears we ever saw. They should be gathered early. Tree vigorous and erect.

Besides these select sorts we have the Cabot, Collins's, Edmond's Buffum, Knight's R. I. Seedling, Lodge, Ontario, Johannet, &c.

October.

This is the month with us—rich in fruits, as M. Jamin says of September—and the sorts are so numerous that the fruit grower must be very careful in his selection, unless he has plenty of space. In fact, it is hard to reject any, so fine are the sorts. I place at the head of the best the

Sheldon.—A roundish russet Pear of long size, combining all the high flavour of Gansel's Bergamot, without its grittiness, with the rich juice of the Doyenné Gris, from which I have supposed it was a seedling. You never tire of eating it, and the large size and keeping qualities of the fruit, as well as the productiveness and beauty of the tree, all stamp it as the best October Pear.

Pratt.—This ranks nearly as high as, but is an altogether different Pear from, the preceding. But its excellence consists in its melting sugary quality and juiciness rather than its flavour. The tree is a magnificent one, growing erect, and yet the fruit is so abundant and heavy that the upright limbs bend till they nearly touch the ground with their weight, and there are no small Pears—a fault with too many sorts. The skin, yellow, traced with pale russet.

Hull.—Another enormously productive and very fine fruit, not remarkable for flavour, but melting, sugary, and rich, like the Doyenné. The tree is spreading, and slightly pendulous, of vigorous growth, and bears large crops of fruit.

Swan's Orange (erroneously called Ononduga).—A Pear almost identical with Beurré Superfin, except in colour and shape. It has the same rich sharp acidity which is so much liked by real Pear lovers. But the Swan's Orange, as its name indicates, is of a rich deep yellow, very handsome, and attractive. It should be gathered early, or it loses much of its excellence. The tree is vigorous, and is a regular bearer every year.

Seckel.—This was sent to the London Horticultural Society in 1818 by Dr. Hosack, and described, with a coloured plate, in the "Transactions of the Society," and is too well-known to need any description.

Merriam.—One of the most popular, though not one of the finest, Pears. Large, round, russety, bearing enormously, and when gathered in time, coming very near to a first-class Pear for excellence, as it is first in every other quality. It may be gathered and handled like Russet Apples, keeps four weeks, and is rarely in good order till gathered two weeks. If left on the tree too long, it becomes mealy. The tree is very vigorous and spreading.

Washington is a small but luscious Pear, very beautiful, with almost the exact appearance of the Forelle or Trout, the red cheek being covered with the spots peculiar to the latter. It is as delicious as it is beautiful. The tree is moderately vigorous and productive.

Other October sorts are the Heathcot, Tea, Mount Vernon, Kirtland, Oswego Beurré, Huntington, Admirable, &c.

November.

Kingsessing.—This is another large, handsome, and good Pear, similar in shape and about the size of a medium Duchesse, with a yellow skin and red cheek, keeping a long time, and of excellent quality. The tree is very vigorous, erect, and bears abundantly, its only fault being that the very heavy fruits are subject to be blown off in high winds, its short stem not yielding to the breeze like the long and slender-stemmed sorts.

Abbott.—The French have a Pear which they call Beurré d'Amanlis (Long de Moukowsky), or Almond Pear; but of all the varieties we have ever tasted, the Abbott has the most pronounced Almond flavour. It is a very beautiful Pear, with a waxy yellow skin and red cheek, and, when properly grown, is a good medium-sized fruit. Its only fault is that it bears so enormously that the fruit requires thinning-out to attain a large size. The tree grows like a Lombardy Poplar, and the fruit keeps from two to four weeks.

Fulton.—One of our oldest American Pears, but yet not extensively cultivated. It originated in Maine, and is very hardy, but the tree is only a very moderate grower, and fine young trees are always difficult to procure. It is best to graft on strong old stocks. It is an abundant bearer. The Pear is roundish, flattened, has a very rich deep russet skin like Beurré Bosc, and is nearly or quite equal to that Pear in quality.

Howell.—Here we have a really excellent November fruit, of large size, pyriform shape, a clear waxy skin of a lemon colour, often touched with light red in the sun, and profusely covered with minute specks. It has no very noticeable flavour, but is full of a very brisk sub-acid juice, refreshing and rich. The tree assumes a somewhat open, irregular shape, and the long branches, when loaded with fruit, nearly touch the ground. It comes in just after the Urbaniste, when there are but very few good Pears, which gives it additional value.

December.

Our winter Pears are yet few, but these few are good, and though accessions to winter sorts are the least desirable, we hope for some addition of new kinds as good as Dana's Hovey, which will keep well till April. Winter Nelis, Beurré Langelier, and Caen du France are about the only foreign kinds which produce fruit except in favourable localities and under favourable conditions, and then with uncertainty; but when the Columbia, and, soon after, the Lawrence were introduced, we were sure of plenty of fruit. The Hovey now fills the early winter season with the most luscious of all Pears.

Lawrence.—This is a Pear quite unlike any of the French or Belgian varieties. It is not buttery, like the Glou Morceau

or Easter Beurré; nor is it watery, like Beurré Langelier. It has a good consistence of flesh, yet is perfectly melting; it has no marked flavour, but is a mass of rich sugary juice—too sweet for some Pear lovers. The fruit is of a good size, clear lemon-yellow at maturity, with a very thin and tender skin, which will not bear rough handling without discolouring its surface. The tree grows freely, much branched, rather slender wood, and rather slow in coming into bearing, but producing very heavy crops. It usually keeps up to the middle of January.

Columbia is a huge Pear, in shape and appearance like a Lemon, with a long stem, and is a very juicy and refreshing Pear, keeping well till February or March. It is very apt to be blown off the tree in any high wind, which renders it ineligible for exposed situations. The tree is a very strong grower, of spreading habit, and a good bearer.

Dana's Hovey.—This variety concludes our list of our select autumn Pears. What the Greengage is to other Plums, or the Muscat to other Grapes, that the Hovey is to other Pears. It is not much larger than the Seckel, and, when gathered in October, has a dull greenish, quite uninviting, look, but as it begins to mature the green changes to brown, and the brown to russet, till, just at the period of eating, they become of a ruddy golden hue, really charming to look at. They are then more like huge drops of confectionery than Pears, the mere cutting of one setting free the delicious aroma, and perfuming the air. The tree is as marked as the fruit, strong, and stocky, with very blunt shoots, and leaves almost as thick and glossy as a Camellia, bearing in clusters, uniform in size, and good size if well thinned, a single tree producing 8 bushels. It begins to ripen December 10th, and continues up to the middle of January.

Curious as it may appear, yet it is a fact that scarcely one of the Pears we have described will grow upon the Quince stock. Some will grow for a few years and then stop; others will not budge a foot. Therefore all these must be grown on the Pear stock. As regards the character of the Pears which M. Jamin enumerates, and which I have stated are comparatively worthless with us, my experience is just the same as that of M. Jamin, who states (p. 458) "that it is only when grown on a wall that most of them (the winter Pears) produce fruit worth speaking of. We should therefore," he further says, "reserve our walls for them to the exclusion of other varieties, which will do pretty well in the open ground." All the kinds I describe do perfectly well as standards in any situation. There are few or no wall Pears in America. I have a line 200 feet long of single cordons, trained obliquely, comprising sixty varieties, just coming into bearing, and I hope for good results. All these Pears have been described and figured in the "Magazine of Horticulture," and several of them with coloured plates in the "Fruits of America," but I hope this brief account will not be without interest to your pomologists.

Boston.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Sea Apple.—Can any of your readers inform me what this is like, and where it is to be found? When touched by the finger, I have been told, it explodes like a puff-ball.—*QUERIST.*

Four Good Forcing Strawberries.—We have this season forced thirteen varieties of Strawberries, and from among them I can strongly recommend the following four, viz.:—Vicomtesse Hericart de Thury and Keen's Seedling as early kinds, and President and Princess Alice Maud as late sorts. If a fifth is required, add Sir C. Napier.—*W. M. STICKLAND.*

Aphides on Currant Bushes.—This pest has again made its appearance in this neighbourhood. The best and cheapest remedy for it is to cut off the curled ends of the shoots and then wash the bushes vigorously with the garden engine. There is nothing like a stream of clean cold water for dislodging insects and cleaning fruit trees of all kinds. If we had time to do this often enough, no insecticide would ever be required.—*E. HOBDAK, Ramsey Abbey.*

Chinese Peaches.—Some varieties of these, according to Dr. Kellogg, grow to the height of 40 to 50 feet, and produce fruit of great size. Marco Polo saw a Peach in the district of Cang-chew that weighed 2 lbs. In general, the larger sorts are considered to be of inferior flavour, although some Peaches in the Emperor's District are said to be as exquisite and meltingly delicious as the best European kinds. Chinese gardeners have the secret art of preserving the fruit gathered in October until January, as perfect in flesh and flavour and as smooth as in the fresh state. It should be noted that in China Peaches are budded upon stocks raised from seed of the choicest varieties.

THE KITCHEN GARDEN.

FORCING FRENCH BEANS.

It was some time after its appearance in *THE GARDEN* that I observed Mr. Gilbert's expression of surprise (p. 416) at the statement that I had 300 pots of French Beans. Like your correspondent, "Ca Canny," he is evidently fond of a joke flavoured with sarcasm, when he says that I must have acres of glass to accommodate such a number, unless they were of the smallest size; but I rather understated the number than exaggerated it, for one of my men tells me the number was nearly 400. Anyone who has a pit covered with a dozen lights and heated with hot-water pipes (manure linings answers well for spring work) can easily have 300 pots of 24 and 16-size, if he makes use of such compact-growing and free-fruited kinds as Osborn's, and others which I place side by side on trial. My few remarks were intended to prove that Osborn's was the best of any—indeed, I have seen no French Bean anywhere grown under any system which can surpass this kind as a free bearer, or for compact habit and excellent quality. It was recommended to me a number of years ago by the late Mr. Thomas Osborn, whose word could always be relied on. I bought a packet, planted it out in a brick pit, and was greatly pleased with the crop. I never had the fortune to get it true since till this season, when I secured a quantity from Messrs. Veitch. It may startle Mr. Gilbert when I tell him it was to economise glass that I potted so many French Beans at one time. It is well known that when a Bean is grown out in the open ground, and has all that it requires, it will produce pods for at least four or five weeks in succession, and why should we not expect the same under glass? The kinds referred to have produced abundantly to the end of May, the roots having grown through the pots into the plunging material, and have defied red spider from the amount of nutriment drawn into the plants, thus reducing the labour of watering. Besides growing quantities on the good old established system, practised by Mr. Gilbert so successfully as to get a peck from forty pots at one picking, I plant out many in pits, either from small pots, or as one would plant in the open ground. As the pits can be spared between the crops of early Potatoes, Asparagus, Tomatoes, &c., and late Melons and Cucumbers, a number of French Beans are brought forward in Vineries or elsewhere ready to fill the structure as soon as the other crops are cleared out. The surface soil is removed after the Beans are finished—the Melons or Cucumbers are in large pots, ready to fill the positions where they are to yield their supply. They are often plunged in the pots and allowed to root through into the soil. After they are done with, the pits give shelter to Lettuce; later, French Beans, or bedding plants, till they are prepared for forcing in the early part of the winter. We thus secure at least four crops in one year from the same structure. I think planting out French Beans in the open bed is not practised so generally as it ought to be. I was pleased, the other week, in passing through the gardens at Canford, in Dorsetshire, to observe that Mr. Dick plants out his French Beans in pits, and grows them as simply as Potatoes. By planting out, the returns are greater, red spider is less to be dreaded, and labour is economised.

Blenheim.

STRAW-MAT PROTECTORS.

THE article written by Mr. Williams, of Ormskirk, on the construction of Potato protectors was re-published in America by the "Agriculturist," a widely-circulated periodical, and the mode advocated has been adopted as a great improvement by some of the leading cultivators there, one of whom writes as follows, in reference to the construction of straw mats on the same principle:—"As the mats needed for covering hotbeds, cold-frames, &c., are required to be of a different size from the Lancashire screens, as well as of less thickness and weight, a different frame is necessary. To make this I procured ten strips, each 7½ feet long, 2 inches wide, 1 inch thick, and four pieces of the same material 4½ feet long, for cross pieces. Each end of the long strips was "halved," for half its thickness. Two of the cross-pieces being laid down, five of the long strips were placed, one in the middle, one for each side, and the other two equidistant from the centre and side strips, as in the diagram, and firmly nailed, this made one half the frame; the other half was made in the same way, and the two hinged together at one end as in the drawing. The space between the long slats, when the two parts are shut together, is 1 inch. To keep the frame from springing apart, after being filled with straw, a hook and screw-ring was fastened on each side at the centre, and two on the end. The frame was now finished, and after laying it upon a pair of tressels, it was filled with straw laid cross-wise and evenly, with the butt-ends projecting beyond the frame an inch on each side. The halves, being fastened by means of the hooks, it is set on end and kept in an upright position by

any convenient support, and is ready to be sewed. The needles used are about 5 inches long and half-an-inch thick, and can be made of any light wood, as the mats, being only an inch thick, do not require such strong needles as those described in April. The sewing is done in four places, the stitch being the same as described for the Lanca-

Frame for making straw mats.

shire mats, with the addition of tying each stitch, making a simple tie each time the thread is put through. This tied stitch is very secure, and prevents any slipping of the twine. This differs from the other mats, you will observe, in having the straw laid crosswise and the sewing done lengthwise, as shown in the illustration by the dotted lines. After the sewing is finished the projecting ends of the straw are cut off even with the frame, which may be readily done with a strong sharp knife. For hot-beds the mats are made 7 feet long, in order that there may be 6 inches to hang over at each end; the frames are made 6 inches longer, as so much is lost in the length by the taking up in sewing. Their width, $4\frac{1}{2}$ feet, allows two mats to cover three 3-foot sashes. These mats are light, flexible, and strong, and can be made about twice as quickly as by the old style of weaving them. Two men with a little practice can readily make ten mats in a day; while, according to Mr. Peter Henderson, two men, by the old plan, can only turn out five mats a day."

Potatoes of American Origin.—In consequence of our offering various silver cups and other prizes for American Potatoes this season, an enquiry has arisen amongst intending competitors as to which sorts, of the great number of varieties in cultivation, were of American origin. In order, therefore, that no confusion may exist upon this point, and that no exhibitor may be disqualified by the exhibition of sorts not American, we furnish the following list of Potatoes which have been introduced to this country from America:—Alpha, Eureka, Snowflake, Brownell's Beauty (syn. Vermont Beauty), Extra Early Vermont, Compton's Surprise, Early Gem, Late Rose, King of the Earlies, Climax, Bresee's Peerless, Bresee's Prolific, Early Goodrich, Garnet Chili, Peachblow, Early Rose. The foregoing names stand about in the order of their date of introduction, the newest varieties being first. —HOOPER & Co., Covent Garden.

The New American Potatoes.—Last spring, I purchased one pound of Snowflake and Eureka Potatoes. Of Snowflake, I had three tubers to the pound; but, being small in size, I was rather disappointed with them. I placed them upon a dry warm shelf in the potting-shed, until all the eyes were sprouted. On counting them, I found that thirty-eight eyes had started. After cutting them into sets, I laid them on dry sand for a few days, in order to get rid of the superfluous moisture. After that, on putting the sets into the scales, they were 3 ounces short of a pound weight. I treated the Eureka precisely as I had done the Snowflake, and found it to be 4 ounces short of a pound. The whole of the Snowflakes sets came up beautifully; but, to my disappointment, within the last ten days, more than half of my plants have shown curl in the leaf, which eventually becomes dried and yellow, and finally drops off, leaving the stem bare. The Eureka, growing side by side, exhibits extraordinary vigour. At two places in this neighbourhood, where the Snowflake is grown this season, the same symptoms have occurred—even worse in one case than in mine. Have any of your correspondents, who grow the Snowflake, observed any symptoms of what I have described. —J. T.

Value of a Garden to a Farmer.—I hold it to be a sober fact that the garden is too often neglected—that it does not profit anyone to so neglect it, for among its products are to be found health-inspiring food, increase of comfort, and a higher satisfaction of mind, together with full compensation in material value. Have we need to ask whether these rewards are well worth the seeking? One hour spent in such a garden, each day at the fittest time, would nearly, if not quite, afford all the labour required. The real pleasure derived from seeing the garden luxuriant in growth, without a weed showing its head, would pay over and over again. I regard it as beyond a doubt that the farmer who will make his garden bring forth thus abundantly, and does not permit weeds to check the tender plants, will so learn from the garden as to gather larger and cleaner crops from less grounds.—"Cultivator."

TREES AND SHRUBS.

HARDY AZALEAS.

THESE are now beautifully in flower, and are so fresh and fragrant that they ought to be more generally grown in shrubbery borders than they are. We saw some magnificent masses of them 8 or 10 feet in height in full flower at Belvoir the other day, and Mr. G. F. Wilson has just sent us some charming trusses of flowers of these Azaleas, which are now making a fine display in the rock-garden at Weybridge. The colours are rose, buff, orange, and orange-buff, and when intermixed with tender young foliage it is difficult to imagine anything more beautiful. In every variety of this plant, when grown well in any deep rich soil, intermixed with Rhododendrons, the different tints of yellow, red, and orange, have a pleasing

Ghent Azalea.

effect among the white, rose, and purple tints of the latter plant. Another attraction possessed by these Azaleas is that the foliage becomes bright yellow and crimson in the autumn. B.

Burrs on the Elm.—Last week I saw, when walking through Bersham Park, in the neighbourhood of Wrexham, a large Elm, the upper part of which was destroyed by burrs. At a distance, it had the appearance of a huge stag's horn; and must have borne no fewer than one hundred burrs. It is allowed to remain undisturbed, as the owner of the property considers it rather ornamental than otherwise. Such excrescences, are, I have no doubt, caused by birds picking off the buds in spring, when another set shoots out, which gives rise to an immense number of small branchlets. This effect may also be seen in the peculiar accumulation of twigs which occur, bird-nest-like, in Birch trees; except that, in the case of the Birch, the bark is not composed of the thick suberous layer which is seen in the Elm. The latter always thickens, or swells, when injured; but, in the Birch, its effects are simply to increase the number of small twigs, without the swelling of bark.—J. R.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Abelia triflora.—This is now flowering profusely on an east wall at Kew, each shoot being terminated by a cluster of Bouvardia-like white flowers and delicate rosy buds. It reaches the top of a wall about 10 feet in height, and its flowers are very sweet-scented.—Q.

The Evergreen Honeysuckle (Lonicera semperflorens).—In sheltered positions this is a most useful Honeysuckle. It has opposite waxy-looking leaves and bears clusters of bright orange-scarlet flowers, which may now be seen in great beauty at Kew.—B.

The Monterey Cypress (Cupressus macrocarpa) as a Side-side Plant.—Amongst the numerous varieties of Cypress which we possess, none equal this for planting near the sea. In this locality (Lynne Regis) it flourishes and grows amazingly, and retains its beautiful dark green colour in spring, when many of the allied species are of a rusty brown hue, caused probably from the action of the sea breezes.—H. MUNRO.

Rhododendrons and Kalmias.—I have not seen such a fine display of blooms on hybrid Rhododendrons for four years as there is this season. Here, in the south-west, they are in full flower and uninjured by frost. Kalmias are also covered with flower-buds ready to open, and of these there will be a grand show in another week or two. These grow magnificently on pure sandy loam rather dry, where Andromedas would die.—W. D. C.

Late Leafing of Ash Trees.—My attention has been called to the fact of the Ash trees being very late in getting into full leaf. Even yet (June 7th) many of them are very bare, and none in the state we usually have them at this time of the year. The foliage of Oaks and other trees is good, and has been all along during the spring quite as early as usual, and young trees, notwithstanding the dry spring, are growing rapidly. For some years Ashes have not been thriving well in this district (the south-west of Scotland) and many trees by no means old have died.—W. H. M.

COMPOSITION AND PROPERTIES OF WATER.

By DR. VOELCKER.

LIKE pure and fresh air, good and wholesome water is an indispensable element for maintaining health and contributing to the comforts of life. It has been surmised that waters which have their origin in crowded cities or in their immediate neighbourhood, must contain ingredients incompatible with their use as a beverage or for general domestic purposes. The sudden outbreak of cholera, and the prevalence of typhoid fever and other infectious diseases in certain localities, have long been associated in the popular mind with bad water and impure air; and there can be no doubt of the great influence which the purity of air and water exerts on general health. An examination of a large number of samples of water both from towns and from the country leads me to the conclusion that towns, as a rule, are supplied with pure drinking water and water better suited for general household purposes than country districts, where the water supply is often not only deficient in quantity, but frequently largely impregnated with sewage and yard and house drainage, thus rendering it unwholesome and unfit for drinking purposes. There are many villages with no other source of supply than shallow wells; and even the country residences of the nobility and landed proprietors I find frequently are supplied with unwholesome water, or water much less pure than that in use in most towns. The purity and suitability for general household purposes of spring, river, and well waters, in the first place, are influenced by the chemical composition of the rocks of the locality in which they originate; and in the second place the properties of natural waters are more or less affected by local sources of contamination, such as the proximity of the well to a cesspool, a house or yard drain, a stable yard, or a dung pit. If a water emits a strongly disagreeable smell, or if it is more or less coloured yellow, or if it is turbid, or if it shows flocculent, floating particles of organic matter or living organisms, no chemical examination is requisite to prove its unwholesome character and unfitness for drinking purposes. It, however, frequently happens that fairly bright and barely coloured water, emitting no smell whatever, nevertheless may be impregnated with an amount of organic impurities and certain saline ingredients which will render it unfit for drinking and cooking purposes. By a careful chemical and physical examination it may be decided without much difficulty, in many cases, whether or not water is fit for drinking, and which of a number of samples is best adapted for general domestic purposes. In other instances the analytical indications are less decisive, and the water will have to be pronounced of a suspicious or doubtful, or, at all events, not perfectly wholesome character. The principal varieties of natural water are rain, spring, river, and well water. These may be conveniently placed in two groups, and described as soft and hard waters. There is, however, no distinct line of demarcation separating the two groups, for the difference between hard and soft water is one of degree and not of kind. Speaking generally, a water is called soft if it contains per imperial gallon not more than 12 or 15 grains of fixed constituents, the greater part of which consists of carbonate and sulphate of lime and magnesia. If there are more than 8 or 10 grains of lime and magnesia compounds in the total fixed residue, and the amount does not exceed 16 grains, the water is said to be moderately hard; and if the earthy matters exceed 16 grains in the gallon it is considered decidedly hard.

Soft Water.

In Nature, water is never found perfectly pure. The impurity of the water is frequently visible to the eye. Fine suspended red clay often imparts a reddish colour to rivers flowing through rocks of red marl, which contain much oxide of iron in their composition; occasionally it appears milky, from fine particles of white clay, which settle with difficulty or only imperfectly after long subsidence. In other instances, river water is contaminated with town-sewage, and then appears muddy and more or less dark-coloured. It is generally brown where it issues from boggy lakes or passes across a peaty country, and in that case seldom is perfectly clear and colourless. Besides the visible impurities taken up from the rocky and other materials which water meets with in and upon the earth, there are others which are held in solution, the presence of which cannot be detected by the sense of sight. The brightest, clearest, and perfectly colourless spring and river waters are never chemically pure; they all contain in solution a greater or less quantity of saline matter and earthy constituents, which are left behind as a fixed residue when the water is evaporated to dryness. The water which descends as rain, having undergone a species of natural distillation, is, if collected in clean vessels and in the open country, the purest and softest of all natural waters. On evaporation to dryness it scarcely leaves any fixed residue. It is contaminated only with exceedingly small quantities of carbonic and nitric acid and ammonia, and light floating particles of impurities washed by it out of the air during its

descent. Rain-water collected in towns or smoky localities, such as manufacturing or coal mining districts, contains, in addition to the traces of atmospheric impurities just named, soot and other mechanical impurities, or constituents dissolved from the materials of the roofs of the building upon which the rain falls. Rain-water collected in towns is always more or less dirty from suspended or mechanical impurities, and generally more or less yellow-coloured by soluble organic matter. In a filtered state rain water is the softest natural water, and most useful for washing purposes or for the feeding of steam boilers. It absolutely prevents boiler incrustations, which cause so much inconvenience, when hard waters, largely impregnated with lime-salts, have to be used in kitchen boilers and steam generators. Rain water, however, is insipid and wanting in the peculiar refreshing taste so much prized in fresh and bright spring-water. On keeping, moreover, the organic impurities enter into decomposition and impart a disagreeable smell to it, which can only be effectually removed by filtration through a charcoal filter. In view of the great advantage of having the command of soft water for washing purposes, arrangements should be made in every country house for the collection of rain in suitable reservoirs. The rain-water may be gathered in water-tight cemented brick-tanks, or it may be stored conveniently in wooden tanks or a number of large barrels. But it should not be kept in tanks lined with sheet-lead, which would be rapidly corroded; and as this poisonous metal passes into actual solution in the shape of oxide of lead, rain-water collected in such tanks should on no account be used for drinking purposes. Amongst the purest natural waters hitherto examined are the waters of several lakes in the north of Scotland and of Cumberland. These waters contain only a small proportion of solid matter per gallon; they are very soft in consequence, and excellent for washing purposes. At certain times of the year they get coloured by peaty matters, which, besides rendering them rather unsightly, give them an unpleasant taste. The waters of Loch Katrine, which furnishes Glasgow with a copious supply of excellent water, has been repeatedly analysed, at all periods of the year, by different chemists, and has been found exceedingly soft and good for general household purposes. These waters are bright and pure, and entirely unexceptionable in point of aëration and colour. Their usual temperature when taken up was from 50° to 52°, showing that their sources are deep-seated and that they preserve the average temperature of the whole year. Their taste betrays no organic taint, but evince great purity, although they appear rather flavourless and somewhat rapid to persons habituated to the use of hard waters. Wells sunk in deep sandy soils or in silicious rocks generally furnish soft waters. Although soft water is greatly preferable to hard for washing or cooking purposes, or for supplying steam boilers, it frequently happens that soft spring and lake waters, especially when much charged with carbonic acid and well aërated, exert a corrosive action upon lead, and become contaminated with soluble lead compounds. It is true that the amount of oxide of lead dissolved by the action of soft waters upon leaden pipes or the sheet-lead linings of water tanks, rarely amounts to more than one part or less in ten millions of the fluid; but, although such small quantities of lead probably will not do any positive injury to persons who take the water habitually, even traces of lead are undesirable in potable waters. Most waters which corrode lead usually act more or less energetically upon metallic iron. The storage of soft water in iron tanks, and its conveyance through iron pipes are frequently attended with inconvenience, for the hydrated oxide of iron, produced by the action of the water upon iron, gives a reddish-brown colour to the water, and renders it muddy to an extent which entirely prevents its use for household purposes. With a view to preventing the corrosive action of soft water upon iron, it has been recommended to substitute galvanised iron for plain cast or sheet iron. I find, however, that galvanised iron is not an efficient protection against the corrosive action of water; and instances have been brought under my notice in which tanks made of galvanised iron were attacked more rapidly than plain cast iron tanks. In galvanising iron it is difficult, if not practically impossible, to cover the surface of the iron with metallic zinc so completely as not to leave here and there small particles of iron of a rough surface unprotected by zinc; and it appears to me that a true galvanic action is set up by the water in contact with the two metals—iron and zinc forming a galvanic pair—in virtue of which action the iron is more rapidly corroded than in the case of ungalvanised iron tanks.

Hard Water.

That springs rising in granitic regions, or in localities where primitive rocks, little acted upon by water, prevail, or which have their origin in siliceous strata, furnish soft water, we have seen. On the other hand, springs which rise in the oolite or chalk formation, and all waters which flow over calcareous rocks, or pass through soils abounding in lime, are always more or less largely impregnated

with carbonate and sulphate of lime and magnesia. It is chiefly to the lime and magnesia, in combination with carbon or sulphuric acid, that what are called hard waters owe their property of curdling soap. Perfectly pure or soft water, in contact with chalk or limestones (carbonate of lime) is capable of dissolving only a very minute quantity of these materials; one gallon of water taking up no more than 2 grains of carbonate of lime. This earthy impregnation is said to give the water 2° of hardness. Most natural waters, however, contain more or less carbonic acid gas, which is a good solvent of carbonate of lime, forming with it soluble bicarbonate of lime. Spring waters in the chalk formation often contain as much as 16, or even 20 grains and upwards, of carbonate of lime in the gallon. Such waters are generally bright and sparkling to the eye, and agreeably sweet to the taste. When boiled they become milky, and leave a sediment which incrusts the insides of kettles and boilers. The explanation of the change which hard waters undergo on boiling is found in the fact that the second equivalent of carbonic acid in the soluble bicarbonate of lime is only loosely united with carbonate of lime. At the ordinary average temperature of the air, hard water contains bicarbonate of lime in a state of perfect solution, but on raising the temperature to the boiling-point of water the carbonic acid, which holds the carbonate of lime in solution, is driven off, and insoluble carbonate of lime is then precipitated, as a sediment, in consequence, with the exception of the two grains which are held in solution by the water itself. The carbonate of lime, dissolved by carbonic acid and curable by boiling the water, expresses its temporary hardness. An artificially prepared hard water, containing 13½ grains of carbonate of lime to the gallon, was observed to decrease from 13·5° to 11·2° of hardness merely by heating it in a kettle to the boiling-point. Boiling for five minutes reduced the hardness to 6·3°, fifteen minutes to 4·4°, thirty minutes to 2·6°, and one hour to 2·4°. The softening effect of boiling does not therefore appear all at once, but the greatest proportional effect is certainly produced by the first five minutes' boiling. In addition to carbonate of lime, hard waters generally contain sulphate of lime and not unfrequently nitrate of lime, and occasionally chloride of calcium. These salts of lime are dissolved in water without the intervention of carbonic acid gas, and therefore remain in solution although the water is boiled, and impart to it permanent hardness. Soft water readily produces a lather with soap; hard water, on the other hand, destroys much soap before a lather is formed. Soap may be regarded as a soluble compound of soda with fatty acids. With lime these fatty acids form insoluble compounds, and hence it is that hard waters are deprived of lime or softened at the expense of soap. The carbonate of lime in water decomposes about ten times its weight of soap in washing, and other salts of lime act injuriously upon soap in proportion to the lime they contain. Carbonate of magnesia and other salts of magnesia act upon a solution of soap in a similar manner to lime salts. On adding a solution of soap to hard water white curdy precipitates are produced, and no lather appears until the lime and magnesia in the water are completely thrown down by the soap solution. The production of lather by the addition of measured quantities of soap solution of a known strength thus affords a good indication of the degree of the hardness of a water. Each degree of hardness indicates 1 grain of carbonate of lime or its equivalent of other soap-destroying earthy compounds, in an imperial gallon of water. The quality of the water supply as regards hardness varies greatly in different towns. The waters supplied by the Metropolitan Water Companies contain from 19 to 24 grains of solid constituents in the gallon, and vary in hardness from 14 to 15 degrees. As an example of a moderately hard water, the water supplied by the New River Company may be quoted. An imperial gallon of this water contains:

	Grains.
Earthy carbonates	12·58
Sulphate of lime	2·41
Chloride of sodium	1·28
Nitrate of magnesia	2·08
Silica and oxide of iron and alumina	·38
Oxidisable organic matter	·32
Total solid constituents per gallon	19·05
Degrees of hardness before boiling	14·4°
„ „ after boiling	4·2°

The water further contains per gallon:

Actual or saline ammonia	·001
Organic or albuminoid ammonia	·003

Wells sunk in the chalk formation usually furnish bright, sparkling, perfectly colourless, and excellent drinking waters, remarkable for their absence of organic impurities. Deep chalk springs, or artesian well waters, however, are generally hard, and not so well adapted for washing or cooking as for drinking purposes. Deep chalk well water generally has a uniform temperature through-

out the year of 50° to 52° Fahr., and thus possesses a desirable coolness which recommends it for drinking purposes. The only and obvious objection to chalk spring water is its hardness, which, when the water is first drawn, is generally from 16° to nearly 18°. A portion of the carbonate of lime, which occasions the hardness, is deposited from the water, when exposed to the atmosphere, with facility, from the escape of carbonic acid gas, and thus by simple storage in reservoirs or tanks for a few days the water becomes much softer. When hard waters are used in steam boilers they rapidly produce a stone-like incrustation or fur, which interferes with the economic generation of steam; and, if not removed from time to time, may become the cause of boiler explosions. Spring and well waters, in districts where Lias clay, Wealden, or Oxford clay abound, are sometimes charged with so much saline matter as to give them a decided mineral taste and to impart medicinal properties to them. A spring of that character occurs in a clay bed at Parton, near Swindon. This spring is used, with considerable benefit, as a remedy for a variety of disorders; and, in addition to the usual constituents of mild saline waters, such as sulphate of soda (Glauber salt), sulphate of magnesia (Epsom salt), and chloride of sodium, the water contains a considerable amount of carbonate of potash, and appreciable proportions of iodide of sodium and bromide of magnesium, which constituents do not occur in ordinary potable waters, and to which, no doubt, its medicinal virtue is partly owing. The alkaline carbonate gives it a strong alkaline reaction.

The best Water for Household Purposes.

The properties which are esteemed of most value in water for drinking and general domestic purposes are:—1. Freedom from putrescible organic matter. 2. Freedom from constant, or even occasional, discolouration by clay and vegetable matter, with perfect brightness and clearness. 3. Freedom from smell and disagreeable taste. 4. Softness. 5. Coolness. Water suitable for all domestic purposes should not contain an excess of saline and earthy matters, and, generally speaking, not more than about 25 grains of solid substances in the imperial gallon. The less lime and magnesia salts it contains the better it is for washing, or cooking, or the generation of steam in boilers. A moderate amount of mineral matter, or even a sufficient amount of earthy carbonates to render water decidedly hard, does not interfere with its use as a beverage, for it may be safely stated that no sufficient grounds exist for believing that the mineral contents of ordinary hard spring-waters are injurious to health. The amount of lime and magnesian salts in chalk-springs, and in waters having their origin in calcareous strata, must be greatly exceeded in general by the quantity of the same salts which enters the system in solid food; and it is a notorious fact that chalk-springs, which seldom contain less than 15 or 16 grains of carbonate of lime, are universally considered to furnish perfectly wholesome, and indeed the choicest drinking water. It is true that chalk-springs are wanting in softness, one of the properties most valued in water; but, on the other hand, the uniform coolness of the water at all periods of the year, its perfect brightness and clearness, freedom from smell or disagreeable taste, and especially its perfect freedom from organic matter capable of further alteration or decomposition, recommend it as an excellent drinking water. In point of softness, the springs in granitic regions, or districts in which primitive rocks prevail, are superior to chalk springs; but, unfortunately, very soft waters are frequently coloured by organic matter, and, as a rule, act upon leaden pipes more energetically, and are more liable to become contaminated with soluble compounds of lead, than hard waters; and this circumstance presents certain disadvantages to the use of very soft waters, such as those from the Cumberland or Scottish lakes. Wholesome and perfectly unobjectionable waters are always bright and free from colour. If a water has a yellowish colour, and at the same time a more or less nauseous taste or smell, no chemical analysis is required to prove its unfitness as a beverage; for such water is certain to contain decomposing organic matter of animal origin, which cannot fail to be a source of serious danger to the health of those who drink it habitually. Light floating particles of suspended organic matter also frequently afford indications of the unwholesome character of water. It is well, therefore, to submit water to a preliminary examination, upon the results of which it will depend whether it is desirable to incur the expense of a thorough chemical analysis. In the first place, I would ascertain whether the water is colourless, or more or less tinged yellow. This may be done by filling a glass tube, 2 feet long and about 1½ inches wide, with the water, placing the tube upon a sheet of white paper, and comparing the colour of the water as seen when looked through the whole length of the tube with the colour of pure distilled water contained in a tube of the same length and diameter. Or the colour may be noted by filling a white Bohemian glass flask, holding about a quart, and placing it on a sheet of white paper, and placing by its side a flask of the same size, filled

with pure distilled water. The best drinking water appears as colourless as pure distilled water. Most river waters show a greenish tint; and peaty waters and waters contaminated with yard drainage or sewage, often appear more or less yellow coloured. By the same experiment the presence of any small floating particles may be readily detected in the water, when the flask is held in front of a dark coloured wall, a strong light falling on the flask from one side or from above. Should the water contain much suspended matter, set the flask aside for a couple of days, and then pour off the clear liquid, or pass it through filtering paper, and examine the colour of the clear or filtered water as before. The suspended matter may be fine clay or marl, and simple filtration or subsidence may render it quite fit for use. In the next place it should be ascertained whether the water has any smell. If it contains appreciable quantities of sewage or decomposing organic matter, it will necessarily have a bad smell; if there are but small quantities of such matters present it is often difficult to decide at once whether the water is free from smell or not, and in that case it is best to fill a large flask or bottle with water, to pour out the greater part of the contents, and then to inhale the air in the partially filled flask or bottle. In this way, and especially if the flask is gently warmed, may be detected a disagreeable smell, which cannot be clearly discerned by the ordinary mode of noticing the smell of water. Another preliminary examination, which anyone may make, is to fill a clean wine bottle quite full with water, cork it down tight, and set it aside for about a week; then draw the cork and notice whether the water gives off a bad smell, or has in any other way undergone a change. At the same time place some water in an open vessel—best a clean glass beaker—cover it over loosely with filtering paper to exclude dust and similar mechanical impurities floating in the air, place the water aside for a week or fortnight, and observe from time to time whether the water remained fairly clear, or whether fungoid growth or the development of plants of the lowest order has taken place. In waters contaminated with even small quantities of sewage the development of vegetable cells and plants of the lowest order is very striking. Lastly, evaporate about one pint of water in a clean small porcelain dish or, better still, platinum capsule; and notice whether the water remains unaltered as regards colour, or whether it turns yellow or brownish on concentration to a small bulk. If a water contains merely traces of organic matter it does not sensibly turn colour on concentration; but, if it is contaminated with an appreciable amount of organic impurities, it turns yellow or brown. Evaporate the water under examination completely to dryness, and notice the colour of the residue. If quite white, like the residue obtained by evaporating to dryness the colourless water of chalk springs, no organic matter is present; but, if the residue is coloured yellow, as is the case with most natural waters, a certain amount of organic matter is present. The organic matter may be harmless, or it may be injurious to health, and in that case requires further examination, which should be entrusted to an experienced and skilled analyst. A good idea of the general character of the organic matter in water may often be formed by noticing the smell which is given off when the residue obtained by evaporating one pint of water is heated over a spirit or gas flame in the dish in which it was obtained, allowing the air free access. Vegetable or peaty matter manifests itself on heating by its peculiar smell; and, moreover, the fumes which are given off, when tested with moistened litmus paper, show a slight acid reaction. Animal organic matter, on the other hand, on heating produces fumes which turn reddened litmus paper blue, and thus have an alkaline reaction; the vapours which are generated when animal organic impurities are exposed to a strong heat possesses the peculiar smell of burned or singed hair or feathers, which characterises all nitrogenous organic matters.

Impurities in Water.

As stated already, in forming an opinion of the sanitary quality of a water, or the merits of a number of samples of potable waters, particular care should be bestowed on the examination of the amount and character of the organic impurities which the water may contain. In towns, no less than in the country, shallow well waters are liable to become contaminated with drainage products containing soluble organic impurities of the most injurious kind to health. In sinking a well, the close proximity of a farm-yard or stable-yard, a cesspool or drain conveying house-slops or sewage, or the neighbourhood of a cemetery, or the depositing place for town rubbish, and all localities where organic filth accumulates, should be avoided as much as possible; and care should be taken to prevent the infiltration of surface water into the well, and by making it water-tight, to exclude percolation from drains near or at some distance from the well. The wells in crowded cities, or the pumps in the close neighbourhood of burial places, are frequently contaminated with organic impurities of the most objectionable character, and are a frequent cause of the outbreak and spread of infectious diseases. Such waters at certain

times of the year are quite bright, free from smell, and scarcely coloured; and their physical properties thus afford no clear indication of anything being wrong with water. At others they give off a disagreeable smell, and appear decidedly coloured yellow. Well waters which do not show a uniform character as regards freedom from smell and taste ought not to be used for drinking purposes. The simultaneous occurrence in water of much common salt, nitrates of lime and magnesia, of much saline and organic ammonia, and of oxidisable organic matter, is an unmistakable proof of the presence of sewage or drainage products. Ordinary spring and wholesome well waters never contain more than mere traces of phosphate of lime; and, according to my experience, phosphates are only found in appreciable proportions in waters highly charged with sewage, or products resulting from the decomposition of animal organic matter. Very soft waters, as mentioned already, not unfrequently contain traces of lead in solution. It may be questioned whether minute traces of oxide of lead exert a positively injurious effect upon health, but there can be no doubt that an appreciable quantity of soluble lead compounds in water affects injuriously the health of man and beast. A remarkable instance of water contaminated with an unusually large proportion of oxide of lead was brought under my notice some years ago. This water on examination was found to contain in the imperial gallon:

	Grains.
Organic matter	5.22
Oxide of iron20
Oxide of lead47
Sulphate of lime	3.14
Carbonate of lime	1.31
Magnesia	1.28
Chloride of sodium	2.30
Alkaline nitrates	2.38
Soluble silica	1.05

Total solid matter (dried at 130° C.) per gallon 17.35

It will be seen that this water contained nearly half a grain of oxide of lead in the gallon; and I ascertained that this poisonous oxide occurred in solution partly as bicarbonate of lead, partly as nitrate of lead. The water was drawn from the leaden supply-pipes connected with a well sunk in close proximity to a manure-heap, which accounts for the abnormally large quantity of soluble organic matter in the water. Drainage from the dung-heap evidently passed into the soft well-water, partly in an unaltered condition, partly oxidised into nitrates, which, in contact with metallic lead, are known to give rise to soluble nitrate of lead. Probably the soluble organic impurities in the water also acted upon the lead and gave rise to soluble lead-compounds. The unfavourable position of the well in this case fully accounts for the contamination of the water with injurious organic impurities, and the still more poisonous lead compounds. The properties of water, which enable it to act at times with unusual vigour upon lead, are little understood, and seem often to arise from the accidental action of local causes, such as the presence of drainings from dung-heaps and decaying organic impurities. These causes are of a kind most to be dreaded in the supply of a single residence, in which, as in the case before us, the whole volume of water may at a time assume the same dangerous composition. The facility with which nitrogenous organic matters are oxidised in porous soils and converted into nitrates adds to the danger of water becoming impregnated with poisonous soluble compounds of lead; for, according to the uniform experience of all chemists who have studied the action of the different constituents of natural waters, no saline matter corrodes lead so readily as nitrates. Most soft waters act more or less energetically upon lead when they are well aerated and impregnated with atmospheric oxygen, which appears to be a primary cause of the action of soft water upon lead, for pure, distilled, or rain water, purposely deprived of air, does not attack lead in any appreciable degree. This explains why some soft waters in contact with lead become impregnated with this poisonous metal, whilst others scarcely attack lead, and may with safety be conveyed through leaden delivering pipes. Hard waters, as a rule, do not act upon lead so readily as soft, especially if they contain carbonate of lime dissolved in carbonic acid gas. The effect of this compound is fortunately to neutralise to an extraordinary degree the usual solvent action on lead which water exercises through the agency of the oxygen dissolved in it. The soluble oxide of lead is converted into carbonate, which, although not absolutely insoluble, appears to be the least soluble of all the salts of lead. Carbonic acid is usually present in moderately hard spring, river, and well waters, and also in most soft natural waters, in sufficient quantity to prevent the solution of a dangerous amount of lead. On the other hand, certain salts, especially sulphates, to which a protecting effect is usually ascribed, do not appear to exercise uniformly that useful property. Hard waters containing an abundance of so-called protecting salts, sometimes corrode lead with remarkable rapidity, but, fortunately, no lead

passes into solution, for the carbonate of lead resulting from this corrosive action is wholly insoluble, even in water highly charged with carbonic acid gas. Even excessively hard waters sometimes rapidly corrode leaden pipes, especially if they have an alkaline reaction. I have in my collection pieces of originally stout leaden pipes, which in the course of less than twelve months were eaten away to a layer as thin as writing paper, surrounded by a thick hard coating of carbonate of lead. Although carbonate of lead cannot pass into solution this dangerous lead compound may be present in water in a suspended state, and in that condition may be mechanically introduced to the system. The practice of filtering water kept in leaden cisterns and intended for drinking purposes cannot, therefore, be too strongly recommended.

Purification of Water.

Spring, river, well, or lake-waters, as it has been shown, are rendered impure to a greater or less extent—1. By suspended animal and organic substances, such as finely-divided clay, marl, flaky organic matters, decaying vegetable matter, and similar mechanical impurities: 2. By soluble organic impurities, which generally colour the water yellow or brownish: and 3. By certain saline matters and soluble earthy compounds, which, in the shape of a more or less considerable and generally slightly coloured residue, are left behind when a measured quantity of any kind of natural water is evaporated to dryness. In other words, suspended—or mechanical, organic, and mineral,—and soluble—vegetable, and animal,—matters, are the ordinary impurities of natural waters, to which have to be added, in exceptional cases, sulphuretted hydrogen, traces of copper, arsenic, or more frequently lead. The means available for the purification of water are:—1. Distillation. 2. Filtration. 3. Precipitative processes, which remove certain soluble earthy compounds.

1. Distillation.—When river, or spring, or sea-water, is kept boiling in a glass retort or metal still, it is converted into steam, which carries with it all the gaseous or volatile impurities that may have been in the natural water, and leaves the whole of the solid saline and earthy matter behind. By suitable cooling apparatus the steam is readily condensed; and if the first part of the distillate, containing most of the volatile impurities, is rejected, nearly pure distilled water is obtained. Except at sea, or for chemical use, this method of purification is seldom resorted to for effecting the purification of water.

2. Filtration.—On a large scale, turbid river-water is effectually clarified by passing it through gravel and sand filter-beds. By this means the mechanical impurities, such as fine clay or marl, dead leaves, and similar accidental impurities, are arrested in the filter-beds, and the water is rendered bright. Filtration through sand also removes to some extent soluble organic matters, which sometimes give a yellowish tint to river-waters, for by passing through gravel or sand, a portion of such organic matters is oxidised, and the filtered water is in a measure deprived of the original yellow tint. The saline and earthy matters dissolved in water, however, are not diminished by sand filtration, or only in a very slight degree. The necessity for this process may be greatly diminished by the use of subsiding reservoirs, which, moreover, have the advantage of exposing the remaining water for a length of time to the oxidising influence of atmospheric oxygen, whereby it is deprived of some objectionable colouring matter. But filtration cannot be entirely superseded, being indispensable as the concluding operation of purification, to remove accidental impurities which may find access to the water, as well as fine particles of clay after remaining for a long time in suspension. For household purposes, turbid and slightly-coloured water may be made bright and almost colourless by the use of the tank or hand filters, which are now supplied in all sizes by the London Water Purifying Company, by Messrs. Atkins, Fleet Street; Mr. Lipscombe, Temple Bar; and other makers of water filters. In most of the tank and hand filters advantage is taken of the well-known property of animal charcoal to remove colouring matter. Vegetable or animal charcoal, moreover, retains effectually every trace of lead which a water may contain, either in solution or in a suspended state, and thus tank or hand filters, in which charcoal is employed as a purifying agent, afford the greatest security against danger arising from the presence of lead poison. In Spencer's Magnetic Carbide Filter, the purifying agent employed is magnetic oxide of iron mixed with carbon. Mr. Thomas Spencer prepares this material by using Cumberland hematite iron ore with a certain proportion of carbon and heating the mixture to a dull red heat in retorts for twenty-four hours. The porous magnetic oxide produced is mixed with coarse sand when used for filtering water, and it effectually removes all organic impurities in a state of putrescence, and any traces of lead that may be present. The most recent invention in water filters has been made by Professor Bischoff, who employs spongy iron as a purifying agent. Bischoff

has experimentally investigated the properties of spongy iron, and, amongst other particulars, found that the organic nitrogen and albuminoid ammonia in water are always much reduced in quantity by filtration through spongy iron, which also diminishes the amount of organic carbon. Filtration through spongy iron thus appears capable of decomposing organic matter. It further removes entirely every trace of lead, and, consequently, is a valuable purifying agent for water. Domestic water filters, on Professor Bischoff's plan, are made by Messrs. Murray & Co., of the Caledonian Pottery, Rutherglen. The spongy iron through which the water is filtered is contained in a stoneware vessel, with a slightly curved bottom. On the top of the bottom is a perforated disc, on which the spongy iron is placed. An opening in the curved bottom is connected with an earthenware pipe, which passes up to the outer side of the vessel to slightly above the level of the spongy iron. Here the pipe communicates with another pipe, passing from the top of the outside of the spongy iron vessel down to the centre of the closed bottom. The latter pipe is open at the top and bottom. An alternate exposure to air and water causes the spongy iron to become oxydised, when it loses more or less of its purifying power. A screw-tap at the lower end of the latter pipe serves to regulate the flow of water through the spongy iron. The spongy iron vessel is placed inside the casing of an ordinary stoneware filter, with perforated bottom, beneath which there is a reservoir for the filtered water. On the top of the perforated bottom is placed a layer, some 4 inches thick, of finely-divided marble or limestone, upon which the water containing some iron in solution flows from the screw-tap. The effect of the limestones is to remove completely every trace of iron from the water. Bischoff's filter has a decided advantage over ordinary water-filters, which soon lose their purifying properties unless the filtering agent is renewed from time to time, whereas Bischoff's filter remains in good working order for years, without requiring the renewal of the spongy iron.

3. Purification of Water by Precipitating Processes.—

An elegant and useful process for softening hard water is that patented by the late Dr. Clark, of Aberdeen. Carbonate of lime is scarcely soluble in pure distilled water, a gallon being capable of holding only about 2 grains in solution. In river or spring-water, however, carbonate of lime is held in solution by carbonic acid, or, in other words, exists as bicarbonate of lime. On boiling, the second equivalent of carbonic acid in the soluble bicarbonate is expelled, and neutral carbonate of lime precipitated. Professor Clark proposed to soften hard water by taking advantage of the property of caustic lime to remove carbonic acid from water. Caustic lime, when added to hard water in sufficient quantity, neutralises the carbonic acid, removes the solvent, and, becoming at the same time carbonate of lime, is precipitated with that originally in solution. In falling down, the precipitated carbonate of lime carries with it a portion of the organic and colouring matter present in most waters, and thus Clark's process not only softens but, in a measure, also deprives hard water of organic impurities. Clark's process is peculiarly well adapted to the softening of chalk springs, which owe their hardness almost entirely to carbonate and not to sulphate of lime, a constituent which cannot be removed by heating as by the lime process, and which renders water permanently hard. The composition of spring or well water from the chalk strata varies but little in different localities. Its hardness rarely exceeds 18°, and pretty uniformly amounts to from 16° to 17½°. Water of that degree of hardness contains in 400 gallons about 1 lb. of carbonate of lime, held in solution by 7 ozs. of carbonic acid gas—1 lb. of carbonate of lime, in round numbers, consisting of 9 ozs. of caustic lime and 7 ozs. of carbonic acid. It is evident, therefore, that the addition of 9 ozs. of caustic or quicklime to 400 gallons of such water will have the effect of depriving it of the 7 ozs. of carbonic acid gas, which holds 1 lb. of carbonate of lime in solution; and that both the lime added and that originally present must be precipitated together as neutral insoluble carbonate of lime, minus a small quantity, amounting to about 2 grains in the gallon, which pure water is capable of dissolving. The original hardness of chalk springs may thus readily be reduced by Clark's lime process from 16° to 18° to from 2° to 4°. This process is sufficiently simple to be left to the execution of a workman of ordinary intelligence. All that is required for him to do is to stir lime water or milk of lime, made by mixing quicklime with water—about 1 lb. to 40 gallons of water—into the water intended to be softened, until the carbonic acid which holds the carbonate of lime in solution is completely neutralised by the addition of quicklime. The spring water, on the addition of the lime water, at first has the appearance of thin milk, but the precipitation of the carbonate of lime proceeds with rapidity, and in the course of twenty-four hours the water may be syphoned off from the precipitate and received in a perfectly clear condition into the supply cistern or tank. The only precaution necessary to be taken is to ensure the absence of an

excess of lime. To this end the water in the settling tank has to be tested from time to time with a few drops of a weak solution of nitrate of silver. This test gives a white precipitate in the original hard spring water, and shows whether the quantity of lime required has been exceeded by the brown colour of the precipitate then formed. In practice the addition of lime water is stopped as soon as a sample of the filtered water from the settling tank gives a brownish coloured precipitate with the nitrate of silver test. In that case more of the hard water is added and well mixed with the contents of the settling tank. After subsidence a sample of the softened water is again tested with a drop or two of a nitrate of silver solution, and the addition of more hard water if necessary is repeated a third time, or until the water ceases to give a brown colour, and yields a white-coloured precipitate with nitrate of silver. Clark's process has been tried on a large scale, and it is in successful operation in many dye works and other manufactories where large quantities of soft water are required. The water used by railway companies for feeding their engines is also softened in several places by this useful and extremely simple process; and by it the Water Works Company, at Caterham, has for some years past rendered hard chalk spring water deliciously soft and pure before delivering it to the inhabitants of Caterham. The only drawback in working this process on an extensive scale is the difficulty of finding space for precipitating reservoirs, and storing for an additional twenty-four hours, the immense volume of water which is required for the supply of large cities. However, this difficulty after all resolves itself into a question of expense, which is of no account in the case of private houses, in which Clark's process can be carried out very well without much difficulty.

Boiler Incrustations.

Ordinary boiler incrustations, resulting from the use of hard water, consist chiefly of carbonate and sulphate of lime, as will be seen by the following analysis of a sample which I examined some time ago:

COMPOSITION OF A BOILER INCRUSTATION.

	Dried at 212°.
	Grains.
Water of combination	459
Oxide of iron	53
Phosphoric acid	58
Carbonate of lime	71.06
Sulphate of lime	12.75
Lime in a state of silicate	1.56
Magnesia in a state of silicate	3.23
Soluble silica	5.70
	100.00

Carbonate of lime separates gradually from hard water when the temperature is raised to the boiling-point, and in the course of time assumes a crystalline form. Hard crystalline masses or stone-like deposits are thus formed in steam-boilers, which greatly interfere with the economical production of steam. The best plan of preventing the formation of boiler deposits like the sample, the analysis of which has been given, is to soften the water by Clark's lime-process. The next best plan, in my judgment, is to add to the water a solution of caustic soda; to allow the precipitate to settle, and to use the clear water for feeding the boiler. Or if it be considered too much trouble to soften the water in this way, caustic soda dissolved in water may be put into the steam boiler. By this means the precipitation of carbonate of lime, as well as the removal of lime from sulphate is effected in a condition in which the lime to precipitate is far less crystalline than it is when no precipitating agent is employed. The formation of crystalline and hard incrustations in boilers may also be prevented to a great extent by placing in the boiler Potato peelings, spent tan, peat mould, coarse sawdust, or chips of Oak wood and bark, of similar materials, which act in a purely mechanical manner in preventing the agglomeration of crystalline particles of carbonate of lime into hard masses. Several compositions sold as preventives of boiler incrustations act mainly in a mechanical way, and others in part chemically and in part mechanically. A favourite composition, sold under various names, consists of a combination of crude tannic acid, produced from gum catechu or Oak bark, or other astringent raw materials, from bone-gelatine or glue. Crude tannic acid and caustic soda are likewise constituents of several fluids recommended as preventives of boiler deposits.—“Journal of the Royal Agricultural Society.”

THE gardener who hung an old coat out to frighten birds away and afterwards found a young brood in one of the pockets, writes to us asking for another remedy.

THE JEANNEL FERTILISER.

DR. JEANNEL, inspector of pharmaceutics, came forward, at the sitting of the 25th of March of the Central Horticultural Society of France, to explain the use of his fertiliser, and to answer all questions put to him on the subject. He produced a number of plants cultivated, under his direction, by M. Rivière, of the Luxembourg, half of them watered with the fertiliser and half with plain water, for plants of the same kind, age and size alike at the starting point. There were *Billbergia*, *Dracæna*, *Aspidistra*, *Curculigo*, and others which I do not remember—in all about thirty. The difference was wonderful. Their size and luxuriance were twice, three times, even four times greater with the fertiliser than with plain water. His recipe or formula is based on the analysis of the ashes of a vast number of ornamental plants, on that of the component parts of such manures as are usually employed for their culture, and on that of the soils in which they are habitually cultivated in pots. He has taken the mean (or medium) of all these carefully-made analyses (as it would have been difficult, and almost useless, to take a particular one for each individual kind), and from the whole has composed a formula, which has answered, and even exceeded, his expectations. The kinds of plants most benefited by it are almost all the herbaceous and soft-wooded plants cultivated for ornament. From my own experience with *Pelargoniums*, and some other bedding plants, *Aspidistra*, and several other greenhouse ones, and from what I have seen in the culture of others, notably in *Begonias*, I can only call it marvellous. *Begonia Rex*, in pots of 10 centimètres, have leaves full as large, luxuriant, and numerous as those in pots ten times the size cultivated in the usual way. This mineral manure not only fertilises the soil usually employed in pot culture, but can actually take the place of it, as plants treated with it can be grown in pure sand. The fertiliser has no smell, is perfectly clean, the volume used is incredibly small, and plants may be kept almost indefinitely in the same pots without shifting; therefore, for lady gardeners, window and room horticulture, it is invaluable. The danger of over-dosing the plant—the only one to be apprehended—is easily avoided by strictly adhering to the rules given which are:—Give once a week each pot about 30 grammes of a solution of 4 grammes of the fertiliser in 1 litre of water; or, what is simpler, dissolve 1 gramme of the fertiliser in 1 litre of water, and with this give each pot a thorough watering once a week; the rest of the week give pure water. A common teaspoon holds 4 grammes of the fertiliser; therefore, such a measure is very useful for dosing a watering-pot holding 4 litres and does away with any need of weighing. The fertiliser is not patented; but the *Pharmacie Centrale*, 7, Rue de Jouy, are authorised to prepare it, and have it for sale in tin canisters as follows:—No. 1, for 50 litres, or 2,000 waterings, at 1 franc; No. 2, for 125 litres, or 5,000 waterings, at 2 francs; and No. 3, for 250 litres, or 10,000 waterings, at 3.50 francs. They also have a modification of it for vegetables, at 1 franc, 1.75 franc, and 5 francs. The doctor never made a mystery of his formula; he gave it out before the Academy of Sciences, and it was published in divers newspapers at the time (1872). I give it here, and it can easily be translated into English equivalents, and made up by any chemist:—

Azotate (nitrate) of ammonia	400	grammes.
Phosphate of ammonia	200	“
Azotate (nitrate) of potassa	250	“
Chlorohydrate of ammonia	50	“
Sulphate of lime	60	“
Sulphate of iron	40	“
Total	1,000	“
Versailles.		F. T. P.

FLOWER SHOWS.

WE suppose that a garden affords the most innocent and perfect pleasures. Lord Bacon thought so, and unphilosophical people who never trouble their heads about the inductive method are at least Baconian in this system. We are all supposed to trace down from “the grand old gardener and his wife,” and therefore have an inherited tendency towards flower shows. The man who does not love flowers is like Shakespeare's wretch who does not love music. The love of flowers is often the finishing grace of a noble character, the redeeming virtue of a debased one. Given the love of flowers, you may in the long run work out the love of many higher things. Moreover, these flower shows do a great deal to cement and decorate provincial life. The general tendency is to be metropolitan, or rather cosmopolitan, and everything that adds to the vigour, healthiness, and independence of country life, cannot be spared in these days. Of course people approach the matter of flower shows from various points of view. Some are terribly in earnest about the prizes. Indeed there is a fashion much to be reprobated in some rich

men's gardens for special cultivations which shall earn paragraphs in the newspapers and monetary prizes, while the general beauty and entirety is unseemingly disregarded. Such gardens are unlike Armida's or even Corisande's. The final sentence of "Lothair" occurs to us—"I have been in Corisande's garden, and she has given me a Rose." The sweet human Roses, in their white and red, blossom at our flower shows. Amid the beauties of animated Nature there are those which honest Goldsmith never classified. Unquestionably there is a good deal of honest criticism on Roses and Geraniums, and the show of Azaleas is always a strong point at a spring flower show. Moreover, there was a great deal of scientific interest in homely vegetables, and even non-scientific eyes view with suggestive complacency green Peas and early Potatoes. Still, as one watches the gay crowds promenading the paths and the smooth sward, or sipping ices and listening to music, it is easy to see that the people who come to the show really make up the largest part of the show itself. It is the opportunity for friendship and flirtation, for the intelligent study of fresh variegated toilets, for counting up our friends who are present, and discussing those who are absent. It is a matter of general congratulation on the excellence of a friend's gardener if a prize has been obtained, or we praise his kindness in sending Ferns and Orchids to aid the ornamentation of the scene. This, then, is one kind of flower show, the large, fashionable gathering to witness the highest outcome of floricultural art in this country. The world has no better show of the kind than the great *fête* days of the Botanical Gardens in our own Regent's Park. There is another kind of flower show increasingly coming into vogue, well deserving of all the help and sympathy that can be afforded. We, of course, mean the working-men's flower show. It is indeed plain and limited in comparison with the richer and more expensive exhibitions. We never knew a working-men's flower show whose working expenses might not be comprised within £40; the other kind of show must cost more than £400. But the moral gains, in the love of beauty, the quickened intelligence, the release from debasing tastes, are at least as great in the one case as in the other. Everyone who is acquainted with what Parson Dale called "the moral topography of a parish" knows the purifying and elevating effect which belongs to the thorough love of a garden among the poor. In a literal, and more than a literal, sense, the "solitary place is glad" and "blossoms like the Rose." Those who have attempted some such shows, especially in the Midland counties, know the great enthusiasm which they evoke, and the high degree of excellence to which they are carried. One of the very pleasing features of such exhibitions is the collection of the window plants by which the dwellers in lanes and alleys seek to make their poor tenements bright, and then, again, the collection of wild flowers made by the young children in wandering on holiday afternoons. To such shows as these a wet day is often almost ruinous, as the state of the exchequer almost depends on the receipts from visitors. We are glad to observe that there is a growing disposition on the part of the wealthy to supplement this source by subscriptions, which will render the prizes really worth the gaining, and also by sending ornamental contributions from splendid conservatories. Such kindness is the acknowledgment of a common taste among all classes for floral beauty, and of the healthy, invigorating, innocent pleasure which belongs to every kind of flower show.—"Globe."

TOUGHENED GLASS.

ON Wednesday evening, the 2nd inst., a paper was read before the Society of Arts by Mr. Perry F. Nursey, C.E., on toughened glass, a subject which has of late attracted considerable attention. The chair was taken by Colonel Strange, F.R.S., and the subject attracted a crowded audience. Mr. Nursey commenced by referring to the important part glass had played in promoting the advancement of civilisation, and to the antiquity of its manufacture, which he showed there was reason to believe was known to the children of Israel in their bondage. The origin of glass, he stated, had been attributed by Pliny to the Phœnicians, who happened to use some lumps of natron on the river shore for resting their cooking pots on, when the fire fused the natron and the sand together, and formed glass. It was more probable, he observed, that the idea was first suggested by the vitreous formation attendant upon the firings of bricks and pottery, and the reduction of metallic ores. After touching briefly upon the development of the glass manufacture in later times in Venice, France, and England, the author pointed out that we were now producing glass which did not differ materially as regarded its physical features from that made in the days of Pharaoh. He then described the physical features of Prince Rupert drops and the Bologna phials, with the object of showing that they and toughened glass were in no way analogous, but opposite; the drops being produced by dropping melted glass into cold water, and toughened glass being made by dipping the heated glass into a heated

oleaginous compound. Both the drops and the phials flew to pieces if the skin were scratched, while toughened glass was unaffected by being scratched by the diamond or cut with the wheel. Mr. Nursey then described the toughened glass of M. de la Bastie, its method of manufacture, and its peculiar characteristics, together with such physical features as had developed themselves as far as investigation had yet gone. It will only be necessary here to observe that the process of toughening consists in heating ordinary glass, and, while hot, dipping it into a heated bath of oleaginous matter. When used by glass manufacturers, the process of dipping would be substituted for the ordinary annealing process, whereby a great saving in time and cost for fuel and breakages would be effected. The author stated that the value of the invention had been appreciated by some of our leading glass manufacturers, who were negotiating with Messrs. Rey & Brothers, of 29, Mincing Lane, for licences to work M. de la Bastie's English patent. Messrs. Powell, of Whitefriars, had already put up experimental toughening tanks, and with incomplete arrangements had succeeded in producing imperfectly toughened glass. The author concluded his paper by observing that the invention was so remarkable, so unique, and apparently so fraught with import to the arts, sciences, and manufactures, as to render it probable that the name of De la Bastie would one day occupy no mean position among those of men by whose genius science had been enriched and the nations practically benefited. At the conclusion of the paper Mr. Nursey experimented with toughened and untoughened glass articles, showing the infinitely greater resistance to the force of impact possessed by the former over the latter. A square of ordinary plate glass, 6 inches by 5 inches by a quarter of an inch thick, was broken by a weight of 4 ounces falling on it from a height of 12 inches. The same weight was then dropped upon a square of toughened glass of similar dimensions from a height of 10 feet, but without breaking the glass. A weight of 8 ounces was then substituted with similar results. Mr. Nursey then threw the weight several times on the glass with great force without breaking it, but he ultimately smashed it with a hammer. Watch glasses, glass plates, coloured and plain, were then put to the test by being thrown violently on the bare floor without damage. One plate was dropped from a height of 5 feet on to an iron grating and rebounded into the air intact.

ROSE NAMES.

THE practice of naming flowers after private friends or public characters is very pretty; but it may be suggested that a little care in the selection of epithets bestowed on such names would not be amiss. Otherwise, it is difficult to say whether poetical compliment or covert satire of the sponsor is intended. What shall we say, for instance of the description appended to the names given to three new Roses, just "sent out" by a leading nurseryman, which we find in the advertising pages of last week's gardening papers? First shall come a lady, and, if the language is rather glowing, we trust that it is not on the whole displeasing to the fair prototype:

MISS HASSARD.—Beautiful delicate pinkish-flesh colour, large, full and fine form, very sweetly scented. First class either for exhibition or general purposes.

But the next is so ludicrously inappropriate that we only reproduce it in the assurance that the original bearer of the name would have smiled at the incongruity of the epithets:

JOHN STUART MILL.—Bright clear red, large, full, and beautiful form of great substance; well adapted for exhibition purposes, being also of strong constitution and free habit. Quite distinct.

Last comes a clergyman, himself a distinguished Rosarian, and we hope his parishioners recognise the portrait:

REV. J. B. M. CAMM.—Very bright rosy-pink, most pleasing colour, large, very full, and fine globular form; very sweet, constant, and thoroughly distinct; growth vigorous.

The moral touch, "very sweet and constant," is peculiarly appropriate to a clergyman, and will perhaps reconcile his admirers to the allusion to what some might deem the physical defects of a rosy-pink complexion and too globular form.—"Pall Mall Gazette."

Good Work for a National Garden.—A learned and practical savant, Mr. Dalbray, began in 1840 in the Garden of Plants, at Paris, a public course of lectures on arboriculture. These lectures were illustrated by experiments on the ground, and were largely attended by landowners and nurserymen from every part of France. In three years old routine systems of culture were done away with, and that of the Vine especially became so much improved that its products soon formed by far the largest item in the resources of that country.

PARIS FLORICULTURAL EXHIBITION.

THE Central Society of Horticulture in France holds, every year, one or more exhibitions in Paris; and, for several seasons, these have taken place at the Palais de l'Industrie, in the Champs Elysées, at the same time as the exhibition of paintings is held. This year, for reasons that it is unnecessary to explain here, this combination, which was advantageous to both parties, did not take place; and the Society of Horticulture had to seek another place for its show. This was found in the garden of the Tuileries, the exhibition taking place partly in the Orangery and partly in a large tent that had been erected for the purpose; but a great many of the horticultural productions were scattered about out of doors under the covered walks, and were exceedingly interesting, although the general effect, it must be confessed, was not as remarkable as might have been desired. The great white walls of the Orangery contrasted badly with the Palms and Rhododendrons which surrounded them; and, in this respect, the show was inferior to those held at South Kensington or the Royal Botanic Gardens. Nevertheless, many of the collections staged were very interesting; and amongst others may be mentioned that of M. Savoye, of Paris, who exhibited Palms, Ferns, Crotons, Dracaenas, and Marantas in excellent condition. MM. Léveque & Sons, the well-known Paris Rosarians, had the best collection of Roses perhaps ever exhibited in Paris. More than four hundred varieties, both Hybrid Perpetuals and Teas, were shown, occupying a space 150 feet long and 6 feet in width. At the back were standards, and next them those of less size, then dwarf plants, and, finally, garlands of cut flowers—an arrangement which produced an effect seldom equalled. Amongst Teas those which attracted most attention were Jean Ducher, Perle de Lyon, Perle des Jardins, and Belle des Massifs; and, among Hybrid Perpetuals, Paul Néron, Richard Wallace, Lyonnais, Comtesse d'Oxford, President Thiers, and Louis Van Houtte. From Algiers came *Chamærops humilis* and other Palms of an interesting character. Two beautiful clumps of Rhododendrons, comprising all the modern English novelties, were staged by MM. Moser & Croux. The *Gloxinias* of M. Vallerand were extremely beautiful, his collection this year numbering not fewer than 100 plants, several of which were furnished with from sixty to eighty flowers and more than that number of buds. The distinguishing characteristic of these *Gloxinias* is their dwarf and sturdy habit, the flower-stems not being more than 6 inches in height, and not one needed staking. Amongst the stronger plants were *Giraudæ*, *Corne d'Abondance*; and, amongst novelties, *Duchesse de Gallieze*, *Charme de Lutece*, *Madame Alphen*, &c. Amongst miscellaneous plants were annuals from MM. Vilmorin, Andrieux, & Cie., *Caladiums* from M. Bleu, and *Clematises* from M. Roy. Amongst novelties, one of the most interesting was a double-flowered new *Begonia*, exhibited by M. Lemoine, of Nancy. This, which appears to have sprung from *B. boliviensis*, is perfectly double; its colour being an orange-red. The flowers are large in size, and the plant appears vigorous. M. Glasse staged a collection of newly-introduced plants, amongst which *Anthurium crystallinum*, *Phyllotæmium Lindenii*, and *Vriesia Malzinei*, were conspicuous. M. Truffaut, of Versailles, contributed *Bromelia agavæfolia*, with scarlet bracts, reminding one of a *Nidularium*, but much larger and more effective. Amongst inventions exhibited were examples of double glazing and improved ventilators, and MM. Berger & Barillon, of Moulins, furnished a new vertical boiler. Such was this exhibition, which with all its shortcomings offered to visitors an opportunity of seeing much that was worth inspection.

A. T.

HELIOTROPE.

How strong they are, those subtle spells
That lurk in leaves and flower-bells,

Rising from faint perfumes;
Or mingling with some olden strain,
Strike through the music shafts of pain,
And people empty rooms.

They come upon us unaware,
In crowded halls and open air,
And in our chambers still:
A song, an odour, or a bird,
Evokes the spell, and strikes the chord,
And all our pulses thrill.

Faint-scented blossoms! long ago
Your purple clusters came to show
My life had wider scope;
They spoke of love that day—to-night
I stand apart from love's delight,
And wear no Heliotrope.

Between to-night and that far day,
Lie life's bright noon and twilight grey,
But I have lived through both:
And if before my paling face
The midnight shadows fall apace,
I see them, nothing loth.

Only to-night that faint perfume
Reminds me of the lonely gloom
Of life outliving hope:

I wish I had been far to-night,
What time the dew fell, silver-white

Upon the Heliotrope! —“All the Year Round.”

NOTES AND QUESTIONS—VARIOUS.

Mulching Peas.—Covering the soil for a space of 2 feet or so on each side of the rows of Peas with manure, or half-decayed litter, has at this season an astonishing effect upon both the quantity and quality of their produce; and on dry soils mulching should always be resorted to.—E. HODDAY, *Ramsay Abbey*.

Carter's Fern-leaved Parsley.—This is a distinct and beautiful variety, quite superior to our best strains of Curled Parsley for garnishing and other kitchen purposes.—DAVID LUMSDEN, *Blorholm*.

The Double Geum.—I have this now in flower, and agree with “G. F.” in his estimate of its merits. The flowers are of good size, and as double as those of a good double Geranium, which they much resemble. They are of a deep rich scarlet hue, and, having long stems, are invaluable for bouquets.—A. D.

Peas in Pots.—I would recommend Mr. Tillery to try for pot culture Laxton's new dwarf Pea Unique, or Dwarf William the First. This is a very perfect kind that branches early and produces fine deep green pods in abundance. It is several days earlier than Multum in Parvo, and on that account is specially valuable.—A. D.

New Cure for the Phylloxera.—This is not sulphuric carbonate of potash, as stated at p. 412; but sulpho-carbolate of potash. Anyone asking for sulphuric carbonate of potash would probably get sulphate of potash—a weak manure. Sulpho-carbolate of potash is a strong disinfectant and destroyer of low organic bodies.—T. FLETCHER, F.C.S., *Warrington*.

Campanula Garganica.—This beautiful pot, basket, or border plant comes into flower at the end of May, and furnishes multitudes of beautiful pale blue blossoms all through June. In the autumn each plant should be pulled to pieces and re-planted or potted as the case may be. Grown well in 60-sized pots it forms a useful plant for various kinds of indoor decoration.—D.

Strawberry Vicomtesse Hericart de Thury.—I have to-day (June 5th) gathered richly-coloured, well-ripened fruit from this Strawberry off yearling plants that were not growing on a warm border, but out in the open ground. This is remarkably early, and I certainly see no prospect of gathering from others for a week or more.—A. DEAN.

The Variegated Euphorbia amygdaloides.—This is now in flower on the new rockery at Kew; its leaves are distinctly margined with creamy-white, and its small orange-yellow blossoms, surrounded by bright golden green bracts conspicuously striped with dark green, are very effective. This, and the Golden Moneywort, well deserve a place wherever a suitable position can be found for them.—B.

Buddleia globosa.—This old-fashioned shrub is now blooming freely at Kew, and is, in appearance, so distinct from all its associates that it deserves a place wherever it will grow. It is liable to suffer during exceptionally severe winters, but a little mulching put over its roots will generally be found to save it. It is a common plant in various parts of the country, but seldom seen flourishing in the London district.—Q.

A barren Magnolia.—We have a *Magnolia grandiflora*, 16 feet high and 10 feet through, on a south wall. It has never bloomed since it was planted, yet it is in good health and makes a great quantity of shoots every year. Eighteen months ago I opened a trench all round the base of the tree, and filled it up with equal parts of loam and manure, hoping to induce it to flower, but without success. I shall be glad if any of your correspondents can give me any advice on the subject.—C. G.

Idesia polycarpa.—This handsome and little known plant, which some call *Polycarpa Maximowiczii*, is now showing bloom at Mr. Crawford's, at Lakelands, near Cork, where it is perfectly hardy, having been growing freely there for these last nine or ten years; it now forms a handsome bush, but has never before shown any sign of flowering. It is to be hoped that it will also ripen its fruit, which is said to be edible, but as yet is, I believe, only known in the form of dried specimens.—W. E. G.

Neapolitan Violets to Bloom in Winter.—Divide the old plants, and plant the runners on a cool border in rich light soil. Plant in lines a foot apart and 10 inches from plant to plant in the row. Keep the surface stirred, and give copious waterings in dry weather. In September, take the plants up with good balls, and plant them in a frame near the glass in a sunny and sheltered situation. Give plenty of air when the weather is severe, and keep off the lights altogether in mild autumn weather.—B. O.

Meconopsis Wallichii.—I have for some years been on the outlook for this plant, having seen it, I believe, figured as blue; but Mr. McNab in his account of the rock-plants at Easter Duddingston informs us that it is yellow, and that the blue one is *M. aculeata*. In the last edition of Paxton's “Botanical Dictionary” it is also said to be blue. Will Mr. McNab kindly set us right in this matter? I cannot call to mind where I saw it figured as blue, nor do I remember ever seeing the plant offered for sale.—T. WILLIAMS, *Ormskirk*.

Gloriosa superba Hardy.—According to Mr. T. Shortt, writing in the “Gardeners' Chronicle,” this beautiful old plant, generally considered a stove plant, is perfectly hardy. It succeeds best in a deep rich peat; a Rhododendron bed is a good situation, as it there finds support from the shrubs, and shows its flowers to great advantage. In cold and damp situations the foot of a north wall is advisable, all that is requisite being a dry bottom in winter, and sufficient depth of soil to secure them from frost.

Ferns and Manure.—Mr. A. P. Calder recently stated that two years ago he planted a Fern-house 120 feet by 10, and that he had used cow manure for the plants, which were thriving well. He had found this manure indispensable for all plants, but particularly for Ferns. He used it only when thoroughly rotted, and made a compost of one-half cow manure and the other half soil from the woods. There is no doubt that for Ferns planted out it may be used with the best effect. I believe Mr. Parsons used manure pretty freely for the enormous specimens of *Osmunda* and other hardy Ferns he used to grow.—W.

Planting the Common Brake under Trees.—I wish to establish this in a certain position under trees, and, having failed to do so, shall be glad of a little advice on the subject from some of your readers.—J. B. [Those who bring loam into their gardens have sometimes a little trouble in preventing this vigorous Fern from establishing itself and dis-establishing more valued plants. Therefore, a few loads of deep sods taken, in autumn or winter, from any place where the Brake grows freely, and placed in the positions where you desire the plant to grow, will effect what you desire.]

Mildewed Peas.—All my Peas after the middle of May are sown in trenches prepared as for Celery. We take out a trench 18 inches or 2 feet wide, and a good spade deep, and put in about 4 inches of manure, dig it in, then fill up with soil, give another coat of manure, and dig it in. When the Peas show flower, if the weather is dry, we give a good soaking with water, and mulch the ground on both sides of the rows to the distance of 18 inches. To have good late Peas it is necessary to water freely, dryness at the root being the main cause of mildew.—J. M.

No. 187.]

[Vol. VII.]

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

PRESERVATION OF CUT FLOWERS.

THE best method of keeping cut flowers fresh ought to be known by all who are fond of floral decorations. Of course, to those who possess large gardens and plant-houses from which to cut daily, this is not so much an object; still, even these may require to send or take flowers some distance, and, unless they are properly packed or preserved, they will, at the end of a long journey, be quite faded and worthless. Where it is possible, flowers should always be cut from plants which have been well hardened off; in some instances, with flowers and foliage, this is not practicable, but, as far as possible, avoid those growing in a strong stove heat. In Ferns, well-matured fronds only should be cut, as young fronds are certain to shrivel up a few hours after being cut, and, consequently, spoil the effect of any decoration in which they may be employed. The stems of all flowers and Ferns should be severed with a sharp knife and not with a pair of scissors, the reason of this being that all stems have minute tubes or veins, through which, when cut, they draw moisture; if these be severed with a sharp knife they remain open, but if cut by scissors they are crushed and become closed, so that they cannot draw up the moisture; consequently they fade in a much shorter space of time than they otherwise would do. Having said so much in reference to the cutting, I shall now turn to the manner of keeping them in water, &c. If flowers are required to keep for only a day or two—I am not speaking of those arranged in vases or otherwise, but merely the sprays as cut from the plants—each variety of bloom should be sorted out and tied into bunches, and these bunches should then be placed in earthen jars or jam-pots, filled with cold water, which should be placed in some cool, dark place till required for use—the wine-cellar is as good a place as can be selected. Many flowers, such as Gardenias, Stephanotis, &c., keep better if cut and placed in water than if left growing on the plant; but, as this class of flowers has short stems, they should be placed in shallow vessels. If Ferns be tied up in bunches like the flowers, it is a good plan to dip them in a pail of water before placing them in the jars; but, if there are any gold or silver varieties amongst them, water should never be allowed to touch them, or it will wash off all the meal. Florists have drawers of zinc, in the bottom of which wet Moss is placed, and on this the blooms are laid; but amateurs are not supposed to have these at hand, and a few tin boxes with air-tight lids—old biscuit cases, for instance—will be found to suffice, and answer the purpose equally well. I have placed fronds of *Adiantum cuneatum* (Maiden-hair) in a tin biscuit box on a Saturday afternoon (the fronds having been well submerged in water first), and when opened on the following Thursday afternoon they were as fresh as when cut from the plant. Many flowers are made to last fresh a much longer period than they otherwise would by means of wiring and gumming, but this comes more under the head of mounting and preparing than of preserving them. Some think charcoal and sal-ammoniac, if placed in water, preserve flowers; but I have tried this and many other methods and found nothing better than spring water as cold as possible. Where small floral arrangements only are employed it will be found a good plan in the evening to lift the blooms out of the vases and place them in a basin of fresh water to stand all night, and submerge the Fern fronds; then, in the morning, fill up the vases with fresh water, and, before the flowers are about to be arranged in them, cut both their stems and those of the Ferns afresh in a slanting direction; the removal of the smallest piece of stem will be enough, for it is only to keep the tubes of the stems open that this is done, as they become closed after being in the water a certain time, and so cannot draw up the moisture required to keep the blooms fresh. Vases of flowers can be kept fresh for a week at a time if they are thus treated. Flowers can also be packed to pass safely through the post and arrive fresh at their destination by a little care and manage-

ment. I have constantly sent by post, all through the winter, boxes of *Maréchal Niel* Roses, *Gardenias*, and flowers of this description, which have always arrived safe and fresh, and the plan I pursue is as follows:—The little boxes in which I pack them are generally 1 lb. tin canisters. I roll each flower in a piece of wet cotton wool and pack them, not too tightly, but so that they will not shake about, and I find that a dozen *Gardenias* can easily be packed in one such box without crowding. Having put on the lid I cord up the box and paper it, leaving the ends open, and the flowers will arrive at their destination at the end of three days as fresh as when packed. If this practice were more generally adopted many could, in large towns, receive fresh flowers from their more fortunate friends in the country.

A. HASSARD.

BUDDLEIA GLOBOSA AND CISTUS LAURIFOLIUS.

A VERY pretty and attractive combination is formed by the association of *Buddleia globosa* and *Cistus laurifolius* in clumps or banks. The *Buddleia* is somewhat taller than the *Cistus*, rearing its spikes of globular clusters of orange flowers above the mass of foliage of both shrubs. While the *Buddleia* is yet in bloom the *Cistus* is gradually unfolding its inflorescence and displaying its white and red-tinted strongly-nerved floral bracts, contrasting pleasingly with its own dark foliage, the lighter green of the leaves of the *Buddleia*, and the flowers of the latter. The foliage of both is clothed with a silvery-tomentum on the under surface, glimpses of which are revealed by every breath of air. The flowers of the *Buddleia* are of considerable duration, and, before they are over, the more evanescent white-petaled crumpled blossoms of the *Cistus* begin to expand. Although the individual flowers of the *Cistus* last only one day, there is a long succession of them—each morning presenting a fresh array. Both of these charming shrubs have persistent leaves, and the *Cistus* may be termed a true evergreen. They thrive best in a well-drained soil in an elevated situation; we have seen them in perfection on the chalk, and in the vicinity of the sea on the south coast. In low humid places, especially where the soil is rich and heavy, the wood does not ripen so well; hence, they are almost invariably rendered unsightly by the frosts of winter. The *Buddleia* is liable to be stripped of its foliage in more favoured spots during very severe weather. It is a native of temperate South America, a country whence we obtain few hardy plants, but those few are exceedingly valuable—*Berberis Darwinii* to wit, several species of *Escallonia* (so useful for covering walls, &c., near the sea), and the beautiful *Passion-flower* (*Passiflora cœrulea*). Doubtless many other things yet remain to be introduced, that will some day play no unimportant part in the embellishment of parks and gardens in the south-western parts of the kingdom. Our *Buddleia* was introduced about a century ago, and in the rich orange colour of its flowers it stands alone among our flowering shrubs. The *Cistus*, like all its congeners, is from the Mediterranean region; but it is much hardier than many of the species, not having been materially injured, even on the stiff clayey loam in the Weald of Sussex since the winter of 1860-61. Moreover it pushed up again from the root after that severe season. Some of the species have much more showy flowers than *C. laurifolius*; and nearly all of them will succeed in dry situations, such as we have indicated, and in the neighbourhood of the sea in all but the coldest and wettest parts of the kingdom.

W. B. H.

A Valuable Shrub (*Cratægus Pyracantha* var. *crenata*).

—This is the best shrub yet tried in Ireland for covering wall surfaces. The old *Pyracantha* is only semi-evergreen in severe winters; this variety is quite evergreen, has a better substance of leaf, and a more glossy green. It is hardier than the common form; the severest winters do not affect it, and the berries are larger and better coloured than those of the *Pyracantha*. I have now had fifteen years' experience of it, and it is the best plant I know of for covering high walls in exposed places. I got it from the Comely Bank Nursery, sixteen years ago, and there are now many fine specimens in the College Botanic Gardens, at Dublin. It is readily increased by layers, strong plants, 2 feet high, being obtained in this way in one year.—JOHN BAIN.

NOTES OF THE WEEK.

— FIELDS covered with young Tomato plants are now not uncommon in the neighbourhood of London. Although in our climate the Tomato can never be grown so easily as a field crop as in warmer countries, yet it has been proved to ripen well in the London market gardens, and perhaps some of the newer kinds may prove an early variety suited to our climate.

— THE handsomest rock or Alpine shrub we have seen for a long time past is now flowering in the Wellington Nurseries, St. John's Wood. It is *Æthionema grandiflora*, which, unlike its older brethren, ascends to the dignity of a compact bush 12 to 16 inches high, bearing numbers of beautiful flowers, arranged in spikes, which are rosy at first, but afterwards change to white. These two hues being visible in all the spikes, the effect is very charming. The plant is worthy of a place in every rock-garden.

— MESSRS. CARTERS' cup, offered as a prize for the best vegetables raised from their seed, will be competed for at the Royal Horticultural Society's Gardens, South Kensington, on July 7th. Besides the cup, which is valued at 50 guineas, and which becomes the property of the employer in whose garden the winning collection of vegetables is grown, a prize of 10 guineas will be awarded to the gardener who has raised them. There are, besides, three other prizes, of the value respectively of 7, 5, and 3 guineas, all of which, including the cup, must be competed for only by gardeners in the employ of gentlemen; the vegetables, except Cucumbers and Melons, must be grown in the open air.

— A NEW form of Potato disease has appeared in the Royal Horticultural Society's gardens at Chiswick and elsewhere. It is a Fungus which attacks the plant when young. The discovery has only just been made, and the disease is being investigated by the Rev. M. J. Berkeley, who regards it with considerable alarm, as probably more formidable than even the old form of Potato disease itself. At Chiswick, its effects have been most disastrous, the entire crop of the American varieties having been destroyed, the tubers never advancing beyond the size of small kernels. It is said to be confined to these varieties, many affected leaves of which have been sent to us from Northumberland. Many years ago, Potato crops suffered occasionally from a disease called the curl. The present complaint is similar to it in outward appearance, although very possibly, indeed, most probably, it is produced by another cause. Our Northumberland correspondent mentions that a friend of his in the neighbourhood of Alnwick, who had reared his plants of Snowflake in pots, has had none of his Potatoes attacked by it.

— MR. CHARLES MOORE writes to us from the Botanic Gardens, Sydney, as follows:—"I am now busy preparing for my winter operations on the new ground lately added to this garden. This will enable me to plant out, with good effect, many of the more hardy plants which I obtained while in Europe last year. As a whole, I made a splendid collection of really beautiful plants, thanks to the liberality of my friends, especially Messrs. Veitch, Linden, Henderson, Bull, Lowe, and my brother, Dr. Moore, of Glasnevin. I am now, and have been since I returned, most anxious about securing suitable plants to send to England in return for those which I have received; but this is more difficult than at first sight might appear. The fact is the majority of the plants at our command here have been sent to Europe, and particularly to England, in such numbers that they have ceased to be of any value in the way of exchange, and one is driven to look elsewhere—i. e., to other countries—for plants likely to be acceptable from this quarter. This difficulty has determined me to send a collector on a cruise, which will occupy about six months, in the missionary ship, "John Wesley." This vessel will touch at the Fiji, the Friendly, and Samoan Islands, the Caroline Group, the Solomon Islands, New Britain, and perhaps New Guinea. My man, a young Dane, will have for fellow-passengers Baron A. Von Hugel and his three assistants (one a photographer), who are also going in pursuit of scientific objects. The results of this voyage will, I trust, enable me to send home some novelties in every way worthy of cultivation. Another ship will shortly sail from this on a purely scientific mission to New Guinea. This vessel, chartered at the sole expense of one of our wealthy colonists, Mr. William Macleay, will be fitted up specially for the convenience and comfort of that gentleman and his assistants; and, although botany is not his particular forte, yet it will not be neglected, as he has given permission to his friend, Sir Wm. McArthur, to send with him three botanical collectors, and if, therefore, New Guinea be as rich in beautiful plants as there is every reason to suppose it is, what a glorious collection of grand things may be looked for. Yet both Sir William McArthur and myself may be disappointed in our expectations. We can scarcely hope to add much to the Crotons or Dracænas superior to those already introduced; our anticipations are more favourable as regards Palms, Ferns, and

Orchids. At all events, these two expeditions will, I imagine, prove a fair test of what plants may be obtained or expected from these islands.

— MR. JOHN NUNN informs us that in a stove at Penllergare a plant of *Aërides odoratum* has produced seventy-two flower-spikes, many of which have over fifty flowers upon them.

— THE large Cantaloupe Melon of the Paris market gardens is now abundant in our markets. This Melon is preferred by many to the common green-fleshed kinds, and we share their desire that it should be more frequently grown in this country.

— THE jury of the Exhibition of the French Central Society of Horticulture has awarded a large gold medal to M. de la Bastie for his discovery of toughened glass, on account of the services it is likely to render to horticulture.

— THE scarlet-berried *Cratægus Pyracantha* (*P. japonica*) fruits much better, it is said, when grafted on the Quince than when grown on its own roots. This plant is so valuable for covering walls that any treatment which ensures or augments its fruiting is well worth attention.

— THE richly laden flower-shoots of *Tropæolum polyphyllum* are now among the most attractive subjects in the large collection of good hardy plants in Mr. Ware's Nurseries at Tottenham. The large single white Rose is also a flower of great beauty and one which is worthy of general cultivation.

— IN a corner of the Cactus-house at Kew a plant of *Carica cundinamarcensis* has produced five well-formed fruits. They are pendulous, about the size of a hen's egg, somewhat Pear-shaped, with the large end near the stalk. Their colour is dark green at present, for they are not yet ripe.

— THREE plants of Fortune's Palm (*Chamærops Fortunei*) in front of the Aroid-house at Kew are now coming into bloom. Their inflorescence, consisting of a much-branched panicle a foot or more in length, is bright lemon in colour, and contrasts strikingly with the deep green hue of the foliage and matted fibrous trunks. The three plants range from 6 to 10 feet in height.

— WE are requested to draw the attention of intending exhibitors at the horticultural exhibition to be held in the Lower Grounds, at Birmingham, on July 1st and following days, to an announcement in our advertising columns, that, in compliance with expressed wishes, the last day for sending in entries has been fixed for Thursday next, June 24th, instead of the earlier date previously announced.

— SEVERAL large clumps of *Lilium Humboldtii* promise shortly to be in bloom in the Wellington Road Nursery. It bears rich orange-yellow brown-spotted flowers, ten or twelve together on a stem, which is sometimes as much as 10 feet in height, but more generally 3 or 4 feet. Its glaucous, undulated, shining leaves are borne ten or twelve together in regular whorls. It is one of the hardiest and best of all the new American Lilies.

— WE hear of a new race of very dwarf Cinerarias, through the medium of the "Journal of the Central Horticultural Society of France." They are said to be uniformly very dwarf, and, withal, to produce large and perfect flowers. They were shown by Messrs. Vilmorin, who are known to take great pains to ascertain the merit of their new introductions.

— AN effort, having for its object the preservation to the public of the large trees at present in the gardens of Northumberland House, has been commenced, and a deputation has been appointed to wait upon the Board of Works, asking that body to take steps for their preservation and removal to the ornamental gardens on the Embankment, more especially the new garden facing Whitehall.

— THE Australians find fruit-drying a very easy process. At the North-Western Province Society's show, held at Carisbrook on the 8th ult., a miner residing at Adelaide Lead exhibited samples of five different kinds of dried fruits, namely, Plums, Grapes, Apricots, Peaches, and Apples, all of which were so good that he was awarded a special prize for each. Some of them, dried five years since, when tasted, had all the flavour of new and good fruit. We hope samples of these may soon find their way to our English markets.

— ALL interested in pleasing combinations of hardy flowers should note the fact that the old blood Geranium (*G. sanguineum*) forms what is perhaps the most beautiful of all edging plants throughout the early summer months. Its graceful foliage, compact but still elegant habit, deeply-coloured handsome blooms, and long period of blossoming are all in its favour in this respect, and make it well suited for a margin to masses and groups of Lilies, Irises, Delphiniums, and other families of hardy plants that bloom at this season.

A GREENHOUSE IN AN ENGINE-ROOM.

SOME time ago, Mr. A. Dawson called our attention to the fact that in the well-organised and interesting factories of the Waltham Watch Company, at Boston, Massachusetts, the engine-room is converted into indoor gardens. Through the courtesy of the London representatives of that firm in Hatton Garden we are now enabled to give a view of this. The chief engineer, being fond of plants, conceived the idea of cultivating them in his leisure moments in the engine-room, and, taking advantage of a considerable amount of glass roofing surface, he succeeded in making what is described to us as a beautiful but peculiar hothouse. We understand that in forming the surroundings of this factory a noteworthy amount of thoughtfulness and good taste has been displayed in planting and gardening. There is nothing that suggests the usual close and sunless dinginess of the manufactory. Windows, opening at all points, let in floods of light,

THE FLOWER GARDEN.

GARDEN VEGETATION IN MAY.

THE month of May, upon the whole, was generally cool. The lowest thermometer readings were on the mornings of the 1st, 4th, 16th, 17th, 19th, and 22nd, when 38°, 36°, 39°, 34°, 35°, and 39° were indicated, while the highest morning temperatures were on the 6th, 9th, 14th, 15th, 21st, and 28th, when 46°, 48°, 49°, 48°, 46°, and 46° were respectively indicated. High winds were prevalent during a considerable portion of the month, with occasional showers, but no heavy rains, the soil being scarcely ever moistened deeper than half an inch. This excessive drought, with that of the previous months, has proved a great drawback to the proper maturing of the foliage of

A Greenhouse in an Engine-room.

give access to the fresh breezes, and open the prospect to charming scenery. On one side is the beautiful river, on the other a park surrounded by the neat cottages of the workmen, while the quadrangle within, with its summer-house and fountain, is planted with ornamental shrubs. In fact, the whole aspect and spirit of the place betray the intelligent sympathy of the managers with their large family of working-people, men, women, and children.

Botanical Names.—The only use of a great part of our existing nomenclature is to enable one botanist to describe to another, a plant which the other has not seen. When the science becomes approximately perfect, all known plants will be properly figured, so that nobody need describe them; and unknown plants be so rare that nobody will care to learn a new and difficult language, in order to be able to give an account of what in all probability he will never see.

—PROSERPINA.

ordinary forest trees, and also to the planting out of annuals and young perennial herbaceous plants. It is also telling severely on many spring-planted evergreen shrubs and young nursery stock, particularly members of the Coniferous tribe, such as *Pinus*, *Abies*, *Picea*, and *Larix*. With the exception of the Plane and Elm, the foliage of few other forest trees at this time (1st June) is thoroughly developed. Many of the American forest trees are still far behind, such as the Liquid-amber, Tulip tree, Pseud-Acacia, American Plane, and Ash, deciduous Magnolias, Nettle tree, Planera, Honey-locust, Hop Hornbeam; also the Hickory, Chestnut, and common Walnut, while the deciduous Cypress and Catalpa are scarcely showing a leaf. Flowering trees, and certain large deciduous flowering shrubs, have been remarkably fine during the month; indeed, rarely does such a show of blossom occur,

but in many cases it has been of short duration, owing to the dry state of the ground. Scarlet and common Horse Chestnut, Bird Cherry, White Beam tree, *Pavia flava*, *Mespilus germanica* and *grandiflora*, white and yellow Broom, white, scarlet, and double-flowering Thorns—indeed, all the varieties of the *Cratægus* tribe—were at their best between the 15th and the end of the month. Laburnum, particularly the varieties known as the English type, have been remarkably fine, while the variety known as the Scotch Laburnum (*Cytisus Laburnum alpinus*) showed only a few flowers, except in the case of individual specimens, which flowered sparingly last year. The trees are generally strong, many of them being 40 feet in height. Last year, with the exceptions just alluded to, this so-called Scotch variety blossomed profusely. At the July meeting last year, it is recorded (*vide* "Botanical Society's Transactions," page 185) that a large Service or White Beam Tree, growing in the Botanic Garden here, assumed a remarkable appearance, two-thirds of the tree being covered with fruit, while the remaining third, facing the west, was clothed with rich green leaves, having no flower or fruit. This season the portion flowerless last year is covered with blossom; while on the other part only a few flowers are observable, and those not fully developed. Hollies of every description, during May, have been loaded with bloom; and, for a time, the ground below them was white with the fallen flowers. They are now covered with innumerable small green berries, betokening, as is generally alleged, a severe winter, although this has proved not always to be the case. Turkey Oak, Walnut, Chesnut, Ash, Birch, Plane, Hornbeam, and many other forest trees are also abundantly in flower, although presenting little show in comparison with the trees previously enumerated. Towards the end of the month the flowering Ash, *Fraxinus Ornus*, was particularly full of bloom. The Lime tree has all the appearance of flowering profusely. This year blossoms are very abundant on many medium-sized Coniferous trees, particularly the *Pinus* section. The finest flowering are *Pinus excelsa*, *Cembra*, *Edgariana*, *tuberculata*, *sylvestris*, some of the kinds being particularly rich in colour, such as the *P. Murrayana*, which, although only 6 feet in height, is red with male flowers. *Picea Douglasii* and *P. nobilis* have also a considerable sprinkling of flowers on them. Many of the Cupressinæ tribe are covered with fruit, such as *Thuja borealis*, *Thuja gigantea*, and *T. Craigana*; also many varieties of Cupressus, including numerous forms of *C. Lawsoniana*. For comparison with future years, I may state that the following trees were observed to be in full bloom, or rather, I should say, in their best condition, on the dates annexed to them:

May 18. Horse Chestnut
Common Lilac
20. English Laburnum
Pavia flava
Hollies of sorts

May 22. White Thorn.
25. Persian Lilac
28. White Beam tree
29. Scotch Laburnum
30. *Fraxinus Ornus*

The dry state of the surface-soil was very unfavourable for many flowering shrubs, such as *Rhododendrons*. Although flower-buds were particularly abundant few were properly matured, except in cases in which water was freely given. Ghent Azaleas flowered profusely, although only for a short time. In consequence of the drought caterpillars are becoming very numerous on the foliage of Lime trees, as well as on that of the Apple, Gooseberry, and Rose. During the early months all the varieties of wall stone fruit were richly covered with blossom; but, with few exceptions, fruit is not well set. The hot sun and drought which prevailed at the time must have injured the blossom. Apple and Pear trees, both on walls and as standards, show a plentiful crop, while Gooseberries, Currants, Raspberries, and Strawberries, have every appearance of yielding an abundant supply. The dry state of the weather, and much sun-heat, have been instrumental in bringing rapidly forward the flowers of many herbaceous and Alpine plants. Subjoined is a list of them as they came into bloom, chiefly on the rock garden here. This list does not include a number of the genus *Saxifraga*, *Sedum*, and *Sempervivum*, or of many Alpine Carices and Grasses, except in cases where they are known to be rare and interesting. At the present time (June) 300 species and varieties, exclusive of duplicates, have been counted in flower. Amongst the plants yielding the greatest display are the *Helianthemums* or Rock-roses, both

single and double, in all shades of colour—yellow, white, pink, and red. All the variety of *Saxifraga* are now at their best, particularly the pyramidal flowering species, also dwarf Phloxes, Aubrietias, *Rosa alpina pyrenaica*, *Veronica verbenacea*, *alpestris* and *V. Guthriana*, *Erinus alpinus* and *E. hispanicus*, *Iberis corifolia*, *Primula luteola*, *Saponaria ocymoides* major, *Daphne Cneorum*, *Onosma echioides*, *Pentstemon procerum*, *Meconopsis aculeata*, *Lithospermum prostratum*, *Linaria alpina*, *Trifolium uniflorum*, *Anthyllis vulneraria rubra*, *Fritillaria Kamtschatica*, *Papaver alpinum* (with its varieties in red, orange, and yellow,) *Erigeron Roylei*, *Hippocrepis helvetica* and *comosa*, *Genista sagittalis* and *pilosa*, *Oxytropis cyaneus*, *Dianthus alpinus*, *Campanula thyrsoidea*, *Dryas octopetala*, *Rhododendron ferrugineum* and *hirsutum*, *Erica hibernica alba* and *h. stricta coccinea*, &c. From the white *Iberis corifolia* to the black *Fritillaria Kamtschatica* flowers of all shades make one rich mosaic work.

Botanic Gardens, Edinburgh.

JAS. M'NAB.

RUSTIC ARBOURS.

As these are generally used as quiet retreats where time can be wiled away with a book, in conversation, or in some light employment, they are not often situated near the mansion or within sight of the flower-beds, but rather in secluded nooks and corners. At the same time the spot selected may be made as varied as the nature of the surroundings will permit. On one estate with which I am acquainted arbours are numerous. One is on the summit of a wooded hill, far away from noise

and bustle, but overlooks a landscape of surpassing beauty; another is in the deep solitude of the thickly-wooded glen or ravine, near a river. Travellers through the wood come all at once upon a neat but thoroughly rustic hut, standing in the centre of a little oasis of velvety lawn, enclosed by a rustic fence made of unbarked stakes, almost hidden everywhere by Roses, Sweetbriar, Honeysuckle, &c. On the Grass there are one or two rustic flower-baskets draped with Ivy, in which are growing bouquets of sweet-scented and other flowers; and, behind, the enclosure is backed up by a pile of roots thrown roughly together, among which grow wild Ferns in profusion, and other hardy plants that thrive in the shade of the tall trees. The small enclosure, which is chiefly laid down with Grass, is kept in just sufficiently good order to create a contrast to the surrounding scene, in a spot so rugged and remote, without in the least detracting from the rusticity of the picture. Another of these retreats is situated in an out-of-the-way corner of extensive pleasure grounds, where a stranger would hardly discover it; there is a romantic charm in having such places in undiscoverable spots. A little pathway turns abruptly off the main walk, and, winding away up the wooded declivity, amongst a thicket of wild undergrowth, lands the explorer on a little plateau, in front of a summer-house so rustic in appearance as scarcely to be detected at a distance among the surrounding trees. The house is of octagon shape. The roof, which is conical in form, and thatched with heather, is supported on eight Oak tree trunks, about 12 inches in diameter, and 7 feet high, and which, having been stubbed up, and not inserted too deeply in the ground, appear as if they had grown where they are placed, at the octagonal angles, the branches having been lopped off and rounded, but not too near to the trunk. The spaces between these rustic columns are boarded up substantially, but so as to leave the tree-trunks visible, both inside and outside. On the outer side, the boards are completely covered with unbarked sapling Oak wood, split, and about 3 inches broad, the pieces being nailed on closely together in rustic pattern work. One of the octagonal sides forms the doorway, to which is attached a porch constructed on the same principle, and at three of the other sides are Gothic windows, or "look-outs," but not glazed. The eaves project considerably, and appear to be supported by Gothic arms—bent Oak branches—thrown out from the tree supports. Inside, the roof and sides are lined with the Silver Moss or Lichen, put on almost as evenly as the pile of a carpet; while here and there appropriate heraldic devices are worked in with darker-coloured materials. The floor is paved with sectional blocks of Larch, planed, smoothed and put together in honeycomb form; and the seats are of Ling woven firmly together. Of course, while adhering to the thoroughly rustic style here indicated, the design may be varied by using different materials in the construction. For instance, I have seen Spruce tree trunks used for supports with good effect, also Larch; but gnarled tree trunks look best; while the inside surfaces may be lined with Sphagnum, washed and bleached before using, and after being put on it may be clipped smooth. Structures such as I have described are inexpensive, and may be erected by handy labourers from materials at hand. Arbours and summer-houses are now among the exhibits of miscellaneous horticultural appliances at the great flower shows; but, though most of them have some pretensions to rusticity, they are not, as a rule, attractive structures. At least, I cannot imagine that the kind of sentry boxes which pass for them, and which are made of such materials as peeled sticks stained and varnished, furnished with paltry windows of stained glass and internal decorations of the same fanciful order, are exactly the things anyone would choose for a quiet corner of his pleasure grounds. These remarks do not apply to all, however, for I have seen some portable structures of this kind in which considerable taste and judgment were displayed, in adapting them to all possible situations and circumstances. The kind of arbours which I have tried to describe are, of course, of considerable size—sufficient, perhaps, to accommodate a score of people—and are as much as possible in keeping with the situation. Bowers and summer-houses, such as are generally provided near the house, and in places where they may afford shelter in an emergency, are less substantial erections generally; but they, too, should always be of a rustic

character, as far as may be consistent with comfort. For example, painted deal seats and fittings are incongruous in such places, and may always be easily avoided. Externally the structure may be draped with climbers, such as the Virginian Creeper—than which there is nothing better—the Clematis, Aristolochia siphon, Roses, or Honeysuckle. J. S. W.

DOUBLE YELLOW AURICULA.

I RECEIVED blooms of the Auricula, of which the accompanying is an illustration, from Devonshire some time ago; and, on learning from Auricula growers that it was scarce, I purchased the stock; and, when the plants arrived, I was much struck with their perfume, which is stronger than that of any other variety of its family. It is a strong-growing free-blooming plant, the flower-stems of which are heavily covered with white powder. It is, in short, a good old-fashioned variety, which cannot fail to become a favourite, and is well worthy of pot culture. A compost in which such plants will succeed may consist of two parts of turfy loam from an old pasture, one part of thoroughly decayed cow manure, and one of coarse river sand and leaf mould. Such plants should at all times have plenty of air, even in winter when ever the weather is favourable.

H. CANNELL.

Woolwich.

PERENNIAL LARKSPURS.

WHEN in suitable soil, these throw up strong shoots and splendid spikes of flowers, which are remarkably showy during June, July, August, and September. The tallest are well adapted for forming back lines to mixed borders, while the dwarfer growing sorts come to the front, and, by judiciously arranging the colours, a pleasing effect may thus be obtained. Beds of Larkspurs are also very effective, the tall-growing sorts being in the middle and the dwarfer ones on the outside. They vary also in time of flowering, some being early, others late, and so a succession may be had through a considerable period. In height, Larkspurs vary from 1 to 6 feet, and the colours include bright scarlet, as in *Delphinium nudicaule*, pure white, pale lavender, and every shade of blue, from clear azure to deep indigo and almost black. Some have pure white, others brown and black centres. The flowers vary considerably in form and size, and the varieties include single, semi-double, and perfectly double imbricated flowers, and the flower-spikes vary in length from 1 to 3 feet. All are perfectly hardy, and may be cultivated in any ordinary garden soil. A deep, good loam suits the Larkspur well, especially if assisted by occasional dressings of manure and leaf soil, which should be placed on the beds as a top-dressing early in spring, and forked in during April. If I were preparing a piece of ground for a plantation of Larkspurs, I should deeply trench and well pulverise it, giving a good dressing of manure as the work proceeded; and, previous to planting, a good dressing of leaf mould, forked in and mixed with the top spit, would be of service. In the case of soils that are tenacious and wet, thorough drainage must be resorted to. Depth of soil is of great importance in the culture of the majority of herbaceous plants. If shallow, and lying on a hard sub-soil, their bloom will be comparatively poor and short-lived, especially in dry seasons and localities. Some recommend Larkspurs to be lifted annually; but if a top-dressing be supplied in spring, moving once in three or four years will be enough. The plants may be divided at lifting-time in order to increase the stock, but no roots should be divided till they are strong. If a few side shoots be taken away in the autumn, and potted in some fine, rich soil, and kept in a cold frame during winter, they will root readily; or if taken off early in spring and put into a slight bottom-heat, the cuttings soon make roots, and grow into plants that flower at midsummer or soon after. A few years ago the Royal Horticultural Society offered prizes at one of its provincial shows for Larkspurs in pots, and the result was satisfactory, and promised well for the future, but it was not repeated. These Larkspurs supply hues of blue not found in other plants, and when well grown have a good decorative effect. Quo.

Primula pulcherrima.—We saw this for the first time in the early part of last month, flowering profusely and vigorously on a piece of rock-work in the garden of Dr. Perceval Wright, Professor of Botany, Trin. Coll., Dub. The situation was by no means a good one, being

much exposed and shelterless; and yet this lovely species appeared quite at home, sending up its stout and stately flowers-stems (some six or more), each bearing a closely packed head of deep lavender-coloured flowers, with yellow centres. Individually the flowers are about the size of those of the Cowslip. At first the head flower is corymbose or flattish. The flowers in the centre are the first to expand, and as those surrounding it follow suite, the centre is thrown up, and the head assumes the form of a closely impacted globe, composed of innumerable flowerets. The flower-stems are some 6 or 7 inches high, tapering towards the top, and remarkable for their succulence and stoutness, and the profusion of farina with which they are dusted. Dr. Wright's plant commenced flowering early in March, first throwing up a bold central scape and flower head, which was followed by five or six secondary flower-stems. It is certainly a beautiful thing, and a real acquisition to the spring garden and lovers of spring flowers. As regards cultivation, it appears to be most accommodating. Perfectly hardy, all it requires is some loam and a well drained spot, such as a patch of rock-work or a dry border can afford it, to grow in. The succession of flowers and the length of time it continues in flower are not amongst the least of its recommendations. Messrs. Backhouse justly regard it as being perhaps the first of Himalayan Primulas of the denticula section. Its identification is not yet absolutely determined, and the present specific name is only provisional.—"Irish Farmers' Gazette."

Two Crops of Mimuli the same Year.—Mr. Clapham, of Scarborough, a most successful cultivator of the Mimulus, has worked up a very fine strain of the maculosus type, some of them unrivalled in character. He gets two crops or successive generations in one year, by treating them after the following fashion:—He first sows on or about the 1st of March, in a gentle heat; the seed soon germinates, the seedlings are pricked off into pans, about fifty plants in each, at one inch apart; the pans are placed in a cold frame, and the seedlings begin to flower in about twelve weeks from the sowing. As they flower the poor ones are weeded out and the good ones potted into thumb-pots and used for supplying pollen with which to fertilise other flowers or to bear seed. A sowing from this seed is made as early as possible after it has ripened—generally from the 4th to the 20th of July, and in the space of from eight to twelve weeks this batch of seedlings also blooms, and from the most promising flowers of this second generation of seedlings is obtained the supply of seed to sow the following spring. These easily-grown and handsome flowers should be more popular than they are.—"Florist."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The White Silene (see p. 482).—Your correspondent's plant is, doubtless, *Silene alpestris*, one of the loveliest Alpines in cultivation, perfectly hardy and of easy growth everywhere.—THOS. WILLIAMS, *Ormskirk*.

Iris Kämpferi.—Of this beautiful Japanese Iris and its varieties there will soon be a fine display in Messrs. E. G. Henderson's Nursery, St. John's Wood. The plants form strong tufts in the open borders and have not been protected in any way; no doubt need, therefore, be entertained of their being perfectly hardy.

Thinning the Blossom Buds of Roses.—This is important, not only where fine blooms are required for exhibition, but also where a continual supply of cut blossoms is in request for room decoration. Our usual plan is to take off at least three-fourths of the buds when in a small state; and, thus relieved, the plants continue growing and blooming throughout the season without intermission.—E. HOBDAV, *Ramsey Abbey*.

Prince's Feather.—This well known hardy annual is deserving of more attention than it receives. It makes a striking centre for a large bed, and as a back row plant, in borders, it is equally effective. It may be sown any time in spring, either where it is required to flower, or in some place from which it can be afterwards transplanted. Unlike annuals generally, it is not liable to go off and leave an unsightly blank before the end of the season.—E. HOBDAV, *Ramsey Abbey*.

Meconopsis Wallichii.—Mr. Williams (see p. 498) is quite right regarding the colour of *Meconopsis Wallichii*. It is the *M. nepalensis* of De Candolle that is of a yellow colour. The yellow species, also called *M. paniculata* by Don, I have never seen in cultivation, nor yet the *M. Wallichii* till last year. It has not yet flowered here. In colour the figure is of a light azure blue, not much inferior to that of the *M. aculeata*, which is truly a magnificent rock plant. The plants of *M. Wallichii* are covered with beautiful yellow silken hairs.—J. McNAB.

A Blue Asphodel.—Can any reader tell me what is the flower alluded to in the following passage from Mr. Ruskin's "Proserpina," Part I., p. 12:—"Rome, 10th May.—I found the loveliest blue Asphodel I ever saw in my life yesterday, in the fields beyond Monte Mario—a spire 2 feet high, of more than 200 stars—the stalks of them all deep blue, as well as the flowers. Heaven send all honest people the gathering of the like in Elysian fields some day!" I have never, as far as I can remember, seen such a plant in cultivation.—THYMUS.

Seed apparently without Flowers.—The production of seed without apparent flowers, as mentioned by Mr. Ware in last week's issue, in reference to *Viola pinnata*, is by no means an uncommon occurrence, particularly in the genus *Viola*; but flowers are there, though much reduced in size, and often altogether destitute of petals. In the common sweet Violet, the conspicuous flowers produce little, if any, seed, whereas the small apetalous flowers borne later in the season are exceedingly prolific. I may add that the true *pinnata* is a South European species, whilst *palmata* and *pedata* are North American kinds.—W. N. H.

JAPANESE MODE OF PACKING PLANTS.

MR. ANDREW MURRAY read a paper on this subject at a recent meeting of the Scientific Committee of the Royal Horticultural Society:—"I have been," he says, "led to bring the subject under your consideration by finding that the mode of packing for transport adopted in Japan is different from ours, and as it is successful, it appears to me desirable that we should examine it with a view of ascertaining whether it embodies any hint that may be adopted with advantage by ourselves. I am not at all challenging the excellence of our present practice. All that I say is, that if it can be improved we should try to do it. I have seen a bundle of plants a fortnight on the way arrive not much the worse, but I have also seen them arrive utterly destroyed, and I presume all nurserymen must be familiar with reclamations from their customers for injury sustained by these packages not being delivered in time. Now if by any new plan we could make them keep for twice as long uninjured I imagine it would be a great boon to these gentlemen. This is what the Japanese do, and their process is to shake the earth entirely from the roots of the plants, and then to envelope them carefully in a kind of stuff seemingly a mixture of dust, saw-dust, fibres, and *débris*, of which I exhibit a portion, and which keeps the roots from injury and from the air during the transit. The way in which I happen to know about it is this:—I have a brother in San Francisco who, as perhaps some of the committee know, is something of a horticulturist. Last season he imported some young living plants of certain species of forest trees from Japan. They arrived in perfect health, packed in the material I have just shown. Struck by the success of the plan, he immediately re-packed a portion of the parcel and despatched it to my sister in Edinburgh. When they reached her most of them were unmistakeably dead, but some two or three still showed signs of life, and it is only now, some months subsequently, that she has given up all hope of bringing them through. They also are dead. Now the committee will remember that the distance from Yokohama to San Francisco is 5,573 miles, which at the rate of 300 miles a day, is about equal to twenty days. The breadth of the Atlantic between New York and Liverpool is only 3,080 miles, and including the transit across the continent from San Francisco takes twenty-three days. The plants thus kept well for twenty days, and if they had remained unpacked there seems no reason to doubt that they might have done so for some days longer. Nurserymen will be able to say how far the degree of success here indicated is worth pursuing and experimenting upon. Our business, I apprehend, is rather to look at the physiological principles required for success, and say which plan seems best to accord with them. The Japanese and European cultivators both start from the same point, viz., shaking the earth from the roots. This, undoubtedly, is sound. There is nothing equal to earth for growing plants in, nothing worse for transporting them in. I do not speak of transplanting with a ball of earth or in earth still attached to the roots. The object of that is to prevent disturbance, breakage, and exposure, and where plants can be transported to their destined place of growth so protected, whether with a bound-up ball of earth or in a flower-pot, no one would propose to improve upon it by shaking off the earth, but where they are to travel not so protected, and for such a distance or time that the earth will dry up and crumble and break away, it can serve no purpose but to injure the more delicate parts of the roots by rubbing against them. It is in the next stage that the difference between the Japanese and European packing takes place. The European ties the roots up tightly, puts moss about them (often moistened with water), and then wraps them up carefully with matting. The Japanese handles the roots more gently, fills up the interstices with his padding, and then covers them with matting. I do not know for certain whether he moistens his padding at starting or not—I believe not. There is no appearance of it ever having been wet—no adhesion—no portions sticking together, and I apprehend that the more correct and better plan in all cases, except where we can calculate on the plants arriving before the moisture has evaporated, is to give no moisture. Moisture about the roots is not an absolute requisite for the survival of plants. In dry summers we have plants living with the earth about their roots as dry as a bone for a foot down. It is the exposure to the air that does the mischief—not the want of water. Every cultivator knows that a plant left with its roots bare will sustain more damage in a couple of hours than another with them covered will in a week. The great secret of successful transmission of plants with the roots out of the earth is the exclusion of air. [The merits of this plan might be easily tested, and we should be glad, about a month hence, to receive from some of our correspondents who may try it, an account of the result. All that has to be done is to take up two or more plants of the same kind, and of equal size and health, and pack one up in the usual English fashion, and the other in the Japanese way, using dry Cocoa-nut refuse for the padding; then put both aside, and see which lives the longest.]

THE INDOOR GARDEN.

RAISING NEW CHINESE AZALEAS.*

By MARSHALL P. WILDER.

MUCH complaint exists among botanists in regard to the hybridisation of plants, as causing confusion—breaking up natural divisions by crossing the species—but, for my own part, I think that instead of confusing the labours of the botanist it has been the means of more clearly defining these divisions, and has given to the world thousands upon thousands of plants far more beautiful and useful than the types from which they were produced. The production of new varieties by the artificial crossing of flowers, by which we can blend the best characteristics of each, affords a source of pleasure and interest to which there are no bounds. Although the art of producing new varieties in this way is of comparatively modern origin, it has now become the acknowledged source of improvement, and the best means for the acquisition of new and improved varieties, upon which we are to rely in future for perfection in the vegetable kingdom. This has been my conviction for forty years, and it has influenced me in practising this art. It is only about thirty years since much attention has been given to the production of new varieties of the Azalea. But those originated within the last twenty years may now be numbered by thousands; one of my friends in Belgium having produced more than six hundred named kinds. Belgium, Germany, and England, have given more attention to the production of new varieties than all the rest of the world. And never before has there been more interest or enterprise in this line of cultivation. Every year brings us something desirable, and now that the Japanese Azaleas (*A. mollis*) are coming to our aid, we may expect even finer results than before. It is quite probable that, by the intermixture of the Chinese and this new hardy species, we may obtain varieties with persistent foliage. These Japan varieties are believed to be hardy; a plant in the Cambridge Botanic Garden, raised from Japan seed, having stood entirely uninjured for several years without protection. The Chinese varieties are easily crossed by the pollen of the Japan sorts, and I have now a pan of young plants just coming up, which are the result of hybridisations made last spring, between *Azalea indica* and *A. mollis*. New varieties are raised by the cross-

fertilisation of flowers, which produce an abundance of seed. The seed vegetates freely, and with good care will produce fine little plants that in two or three years may be made to bloom, and thus give us early the results of our efforts. The plants which I hold in my hand [Mr Wilder here exhibited two seedlings which were acknowledged by all to be of remarkable size for their age], are the result of seeds produced by the *Souvenir de Prince Albert* fertilised with the pollen of various other kinds. The seed was sown last winter, and came up in March or April. These plants, as they stand, measure more than a foot in height, and I expect to have them in flower next year. To accomplish this, I shall either take off the tops, and graft them on strong stocks, or, what is surer, inarch the

tops on to strong stocks. The process of grafting may be either by split grafting or by a side graft, but in these cases the plants should be laid on their sides in a close frame and in very mild heat; or they can be worked by standing the stock upright, and slipping over the whole a common glass lamp chimney, stuffing the top with cotton, so as to keep the air close and the graft fresh until a union has taken place, and the graft begins to grow. This is called the "stified graft," and was introduced to me thirty-five years ago by the Chevalier Soulange Bodin, for the propagation of *Camellias*, *Azaleas*, and other hard-wooded plants. The *Azalea phœnicea* has been found to be one of the very best for stocks. Cuttings are made of half-ripened wood, cut smoothly, just below a leaf-bud. They may be planted in pans or pots, very thoroughly drained with broken pots, on which should be a covering of Moss, or spent Hops, which I have found to be excellent for drainage. For soil we use two-thirds

Aralia Guilfoylei (see p. 506).

peat and one-third fine white sand, but they will do equally well in sand alone. As regards temperature, cuttings of the *Azalea* will root in a shady, cool place in the greenhouse. This is, however, a slow process, and the better way is to cover the pots with bell-glasses, or, which is still better, to place them in a bed with a mild heat. In this way cuttings root very freely, and in two years, with good care, will make pretty blooming plants. In the production of new varieties, if you desire white varieties, use white sorts to cross with; if red, then use red; if variegated sorts are desired then impregnate with the pollen of striped or spotted sorts. For this purpose I use a small camel's-hair pencil, which I have always in my pocket, taking the pollen from one flower and transferring it to another. The proper time to fertilise the *Azalea* is about three days after the flower is

* Read before the Massachusetts Horticultural Society.

open. At this time the stigma will be well developed, and in such a state as to receive the pollen readily, and before the stigma becomes too glutinous. But we desire to go farther than merely obtaining beautiful varieties, and to make the Azalea hardy, so as to stand the open air like the deciduous species, and this I deem quite possible with the varieties which we shall obtain from the crosses of the Japan species. The white Chinese Azalea is nearly hardy in England, and has stood in some places for many years without protection. A cross with this and the Japan species would give hopes of success. Although I have spoken of hybridisation as the means of producing new varieties no plant is more given to what is called sporting than the Azalea. Some of the very best varieties we have owe their origin to a freak of Nature; that is, to flowers which have departed from the natural type and given flowers of other colours. To these we have given the name of sports. They are perpetuated by grafting from the sporting branch. The seed is gathered in October or November and kept until January, when it is sown in shallow pans in two-thirds peat and one-third fine sand. When the young plants have attained the height of 2 inches they should be potted off into thumb-pots and placed in a bed of tan or similar substance, where the bottom of the pot will not dry suddenly, near the glass in the shady part of a pit or greenhouse. These pots, as well as those afterwards used, should be most thoroughly drained. In the treatment of established plants I have drained with potsherds, with a covering of Moss or spent Hops, so that the plants might take a full supply of water without the earth becoming sodden and sour. The plants should, at all times, have a regular supply of water, especially when in flower and while making their growth. I have found that it is well to keep them in the greenhouse until the weather becomes warm outside, so that they may ripen their wood thoroughly. They should then be removed to a cool shady place; or, if allowed to receive the sun in the middle of the day, they should be plunged in some substance so as to prevent the roots from becoming injured by the heat of the sun on the pots. Mr. Hunnewell's method is to pile soil around each separate pot, and I have never seen any Azaleas in better condition than his. The best season for potting is immediately after the plants have made their growth in the spring, and the best soil is three parts fine old peat and one part fine sand. The Azalea may be forced early, and a succession of flowers may be had from December to May if kept in a cool house until wanted for forcing. One word in regard to the form of plants. A natural form, grace, and beauty, has been given to every species of plant, and our treatment of them should correspond with that rule of beauty which has been given for our guide. True, there are from some cause often naturally ill-formed plants, but these are exceptions to the general rule. In a word, I am not in favour of the modern method of training and tying down the branches to make exact spherical, conical, or other geometrical forms. Such are not the natural forms, and I think we should follow Nature as closely as we can in the training and pruning of the Azalea, only early removing such gross or rambling branches as are necessary to keep the plant within proper bounds. This training of Azaleas into geometrical or fantastic forms is just as unnatural as to train an American Elm into a pyramid or a Norway Spruce into a standard with a high stem and a globular head. Nothing in the way of ornamental plants under glass can surpass the gorgeousness of the Azalea, with its rich and varied colours, and it is not probable or perhaps possible that any plant will ever exceed it in beauty. A large conservatory full of these plants, when in full bloom, may be truly described as effulgent with beauty and glory.

In the discussion which followed the reading of this paper Mr. Charles M. Hovey said that the Azalea had long been a pet of his, and Colonel Wilder had given us a fresh reminder of its beauty. Mr. Hovey was one of the first to raise new varieties from seed, having, in 1837 or 1838, sown a large quantity, and produced a great many fine seedlings, among them a white variety which he named *alba crispiflora*, and which he thought scarcely surpassed. Some of the plants then raised are now large specimens. Fine large plants can only be obtained by grafting. He agreed with Colonel Wilder that the formal training practised by some cultivators is unnatural. Still, to produce a well-shaped bush one cannot dispense with pruning, and the best-formed specimens are made by a combination of tying and pruning. Grafting must be done when the wood is comparatively soft; he had inserted thirty, forty, or fifty grafts on a single plant. Some of these will not be in the right place, and will require tying to a certain extent, in order to have the wood equally distributed. The production of new seedling varieties is of great importance. By hybridising with *Azalea amœna* a hardy race might be got better perhaps than from *A. mollis*, and also an ever-green one, which would be desirable. We cannot do much with *A. ovata*, though a beautiful species and probably hardy. Like all plants of the Heath family, Azaleas require some pro-

tection. No plants are so quickly injured in the buds by frost; an early frost before the plants were housed, which did not destroy the *Heliotrope*, injured every flower-bud of the Azaleas, though the foliage was not touched. The terminal leaves hold the moisture from the dew around the buds. The point we should aim at in raising seedlings is to get a variety with good flower, foliage, habit, &c. Many varieties, when in bloom, are so densely covered with flowers that it is of no consequence that they have no foliage. The plants may be frozen without injury, if kept dry; but, if wet, the flower-buds are destroyed. In answer to an inquiry as to the process of grafting, Mr. Hovey said that he takes off the end of a shoot, pares off one side of both scion and stock, and ties on as a side graft. The plant is then laid on its side and covered with a newspaper, or placed in a frame, when, if kept close and warm, they unite and may be removed in six or eight weeks to the house. Grafting, Mr. Hovey said, can be done at any time; but from the 20th of July to the 1st of September is best. The seed is remarkably fine, and should be sown in sandy loam or sandy peat, with a little of the same over it. It should be protected with a glass laid over the pan, and watered very cautiously. Worms are apt to trouble the seedlings. As soon as they are large enough to handle, they should be pricked out in boxes a foot square, about fifty in a box. On the 1st of June they should be potted and put under a whitewashed frame. Mr. Wilder said that his method was to sow the seed in broad pans in January or February, and pot when the plants are 2 inches high, in pots one-third full of drainage. He had petted his plants, which would perhaps account for the size of those exhibited.

ARALIA GUILFOYLEI.

This fine ornamental stove plant is a native of the South Sea Islands. It is of shrubby habit, and has an erect stem, copiously dotted with lenticular markings. The leaves, which are pinnate, have smooth terete petioles, and, in the case of young plants, are made up of from three to seven-stalked, oblong-bluntish leaflets, which are sometimes obscurely lobed, and irregularly serrate; these leaflets vary in length from 2 to 3 inches, and are neatly and evenly margined with creamy-white, the surface being in addition occasionally splashed with grey. The annexed illustration (see p. 505) represents a plant of it as seen in Mr. Bull's establishment in the King's Road. It grows very freely in a fresh open compost of peat, loam, leaf mould, and sand, and enjoys the temperature of a warm moist plant stove. Wherever variegated-foliage plants are appreciated this cannot fail to be a favourite.

B.

LILY FORCING.

AMERICANS usually import Lilies from Germany in the autumn, and care should always be taken to select from among them such as are strong and well-ripened for forcing; for upon this success greatly depends. Early in November a number of shallow boxes or flats, about 4 inches deep, are prepared. In these the bulbs are planted as thickly as they will stand. They are then watered freely and placed out of doors in an open position, exposed to all kinds of weather. About the 1st of December they are usually placed in a warm house—that devoted to *Poinsettias* is the best—the boxes being placed on the top of the hot-water pipes. They are then covered 2 inches deep with Swamp Moss, such as is used for packing plants, and are kept well supplied with moisture by sprinkling them two or three times a day with water. As soon as the young plants show their flower-stems, they are removed to a part of the house where there is more light, but, as yet, they are not exposed to the rays of the sun. When they are removed from their position upon the pipes—these being under the benches—the leaves are white and blanched, and, consequently, care must be taken that they are gradually inured to light. After this the leaves will become perfectly green, whilst the flower-stems become erect and the flowers well developed, the latter being marketable at Christmas and New Year, and bring from £2 to £3 per 100. Succession crops are introduced during the winter in order to supply the demand which exists for these flowers, and which, in New York and Boston, is greater than the supply. Mr. Wilson, Astoria, Long Island, imported 200,000 last winter. When the bulbs have finished flowering they had better be thrown away; they are worthless for any purpose.

JOHN HOWATT.

Aspect and Elevation of Hothouses.—In the case of houses intended for early forcing, we are almost sure to give them a full south aspect and a sharply-inclined roof; flat houses, for successional work, with any other aspect, being the exception. My own impression, however, is that more skill is necessary to have at all times

enough of everything than to have any given crop fit for use at a certain date, possibly at the risk of having a deficiency of the same kind of produce a month later. It therefore becomes important to have succession houses as well as houses for early forcing. A moderately low-roofed house does not require more than half the amount of ventilation that a steep-roofed one does to keep the temperature at its proper level. I am no advocate for shading fruits of any kind; but I have heard of forcing houses being, what is termed, "improved," until even tropical fruits need shade. Architects recommend lofty buildings, and, as a rule, make provision for plenty of light and heat; but, in practice, large houses are found to be unfavourable to the growth of plants. Gardening becomes poor, indeed, when the houses, and not their occupants, form the chief attraction; and that the best results can be achieved in houses comparatively small in size, I am confident from my own experience.—JAMES GROOM, *Henham, Suffolk*.

Glazing with Tile-shaped Glass.—In his account of the flower show held in Paris the other day, your correspondent has omitted what, to my mind, was the most useful novelty exhibited. This was a common iron sash glazed with concave panes of glass; these carry off the rain and melting snow like so many gutters, preventing any filtration of wet into the putty and iron work. The price is the same as that of flat glass, a very slight modification only in the manufacturing of it being required. The white hot cylinders, when split and allowed to fall open upon a flat iron table form flat panes; but, in the case of concave glass, for the flat surface is substituted one of the required convex curve, and the panes take the required shape of themselves. The lowest pane is so raised by putty or lead as to lie properly on the flat transverse bar or edge of the sash. Perhaps if this lower bar were placed on edge and bevelled out at the top to suit the shape of the pane it might be an improvement.—F. T. P.

Very Doubtful.—A novel cure for sickly pot plants is given by M. Willermoz, in the "*Bulletin de la Société Horticole de Soissons*." He states:—Many growers are ignorant of the fact that pot-plants which have become sickly through over-watering, planting too deeply, &c., may be greatly benefited by giving them water at a temperature of 133° to 144° Fahr. For some years past M. Lucas, of Hohenheim, has pursued this method, instead of changing the soil, and he assures us that it never fails. Amongst plants so treated he mentions Palms, Roses, *Ficus elastica*, and others. The soil should be well stirred, and soaked with water heated to a temperature of 133° to 144° Fahr., until the latter runs off freely from the bottom of the pots. After a few days the sickly plants recover their original look of health and vigour, and begin to grow again. It is noticed that the earth becomes much more friable after this treatment, and, when dry, has all the appearance of fresh soil.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Two-spathed Flamingo Plant.—I flowered some seedlings of this plant for the first time last year, and the first that opened its spathe proved double, and much more perfectly so than that of which you have given an engraving at p. 481, inasmuch as the second spathe was all but as large as the first, and both were large for a young plant. I looked forward to the opening of the next spathe on this plant, hoping that double spathe were to be a permanent characteristic of it; but I was disappointed. It has come single ever since, and I expect that Mr. Gumbleton will find that his will do the same.—W. THOMSON, *Clovenfords*.

The White African Lily (*Agapanthus umbellatus albus*).—This is perfectly hardy, and exactly resembles *umbellatus*, except that its flowers are delicate paper-white instead of blue. In pots it is useful for conservatory decoration, and it is also valuable for cutting, as its flowers look pretty and distinct in bouquets and button-holes.—B.

Plants for Window Boxes.—The following succeed well with me in an eastern aspect:—Canary Creeper, Crimson and white-flowered Daisies (now very effective), common Stonecrop (*Sedum acre*), *Rhodeola rosea*, a very pretty glaucous-leaved succulent plant which comes up clean and fresh every spring. Scarlet and yellow-flowered *Tropæolums* are also very showy, and the foliage is always of a bright green tint. *Cobæa scandens*, planted out a month ago, is growing very rapidly, as also is the Virginian Creeper.—B.

Cool Treatment of Orchids in Winter.—I have been subjecting my Orchids, especially Vandas, to a very low temperature in winter, and I imagine more healthy or vigorous plants do not exist anywhere. I showed a spike of *V. suavis*, the other day, at South Kensington, with nineteen blooms on it. I had a plant photographed, to show how finely they keep their foliage to the bottom, and to indicate how strongly the leaves grow. Mr. McMoreland called here last autumn, and told my son that he never saw Vandas so robust as mine were, and all Orchid growers will agree that he is a good judge.—W. THOMSON, *Clovenfords*.

Venus's Fly-trap (*Dionæa muscipula*).—This interesting little plant is just now producing its pure white Primrose-shaped flowers on pale green scapes about a foot in height in abundance in the Wellington Nurseries. Potted in fibrous peat and fresh Sphagnum Moss, it is one of the easiest of plants to cultivate, but likes a warm and moist temperature with plenty of air. If the atmosphere of the house is dry a bell-glass must be placed over it to induce it to grow freely. I saw hundreds of fresh little specimens the other day in the nurseries just named growing close under the glass in a warm greenhouse, and, wherever the wall on which they were standing was naturally moist, there the plants were in better health than those in dry places.—B.

THE KITCHEN GARDEN.

POTATO-CULTURE AT KILLERTON.

As this is the season for earthing-up Potatoes, a description of the mode of culture that I have for several years practised with success may be useful. The ground in winter is well prepared by being dug up in ridges and exposed to frost. About Lady-day, I have it forked down, spread manure on the surface, and then plough in the Potatoes 6 or 7 inches deep and 2 to 2½ feet apart. When they begin to break the ground I harrow them over with a pair of very light harrows on a sunny day, which kills all the small weeds. When about 8 or 9 inches high they are hand-hoed, and then require no further attention till they are dug up the first or second week in August. Last year I began to dig them on the 29th July, as the Regents had begun to grow out. In digging, they all hang to their haulms, and considerable caution must be exercised in handling them, in order that they may not be bruised. They should then be put in a long narrow heap, and covered with dry litter or Fern, thatched with "reed" or prepared straw to keep them dry. This straw is similar to that used in this neighbourhood for the roofs of cottages and other buildings. The straw for making reed is thrashed and combed by hand. In a fortnight or three weeks they should be looked at, to ascertain if any are diseased; and, if this is not the case, they should be gradually earthed up, the ridge being left unearthed to prevent them heating. Last year I had some under a north wall which were not picked over until Christmas, when they were removed to the lime and sand floor of a dark cool cellar, where they keep much better after the end of the year than in ridges or caves out of doors. The disadvantage of earthing up is that the first leaves are buried, and a fortnight of the short season before the disease sets is lost, which must be taken into consideration. I believe the crop is no heavier for earthing, and the practice entails much extra labour at a very busy time. My remarks apply to good, well-drained ground—in wet soils earthing may be advisable. I find that the true Lapstone Kidney is one of the best kinds, and it does not run out if grown in the same ground; I have grown it here for seventeen years. Carter's Ash-top Fluke, I consider, is the same sort grown side by side here. York Regent is one of the best late Round kinds. With me it is a heavier cropper than Paterson's Victoria, and more free from disease—both are excellent in quality, but the latter is better for cropping between, as the haulm is erect in its habit. The York Regent soon runs out, or degenerates, if grown year after year on the same ground; but on planting fresh seed it produces, with good cultivation, very heavy crops. Although the tubers readily skin, and appear very unripe when taken up, the quality is excellent afterwards throughout the whole season. Many of the cottagers in this neighbourhood have followed my advice in reference to Potato-growing, and have, I believe, found the advantage of doing so.

JOHN GARLAND.

Killerton, Exeter.

New American Potatoes.—Like your correspondent "J. T." (p. 491), I purchased 2 pounds of the new American Potato Snowflake, and 1 pound, containing three tubers, I cut into twenty-five sets, that being the number of eyes on them, and, after drying these in sand for a few days, each set was planted in a small pot and placed in a cold frame to sprout. They have since been planted out; and, although touched a little by a slight frost on the morning of the 30th of May, they are growing vigorously. No signs of any curl on the foliage have yet been perceived on any of the plants like that mentioned by "J. T." as having attacked his plants. The other pound of Snowflake also consisted of three tubers, and I cut them into thirteen strong sets and planted them out at once in a row. The plants now are very vigorous, but show no symptoms of curl in the leaf. The dwarf foliage of Snowflake and the colour of the flower are of the Early Rose type, and they are exactly similar in foliage and flavour to plants of the Wild Potato I once raised from Peruvian or Chilian seeds. The Chili Garnet, a variety of Wild Potato, is, I believe, the parent of the Early Rose, from which all the other new American kinds have sprung. With me the variety named Brownell's or Vermont Beauty is the strongest grower of the newer kinds, and the tubers are large and fine-shaped, and do not, when cooked, possess so much of the peculiar early flavour as is the case with the Early Rose and others on some soils.—WILLIAM TILLERY, *Welbeck*.

Picking off Potato Blossoms.—I observe some discussion in the papers on the practical utility of picking the blossoms off growing Potato plants to increase the growth of the tubers. According to theory, this would be the result, the formation of seed always tending to exhaust more or less the vitality of the plant. Many years ago, we were told that the crop would be increased one-third by carefully removing all the blossoms. I gave it a careful test in rows side by side, but ordinary measuring did not indicate the slightest difference.—A.

THE FRUIT GARDEN.

RIPE AND UNRIPE GRAPES.

I LATELY saw a Vine, on a portion of which the fruit was ripe; while, on the rest of it, the bunches were only just formed. This was caused by the longest rods being taken from a cold house into a Pine stove, through an aperture in the divisional wall. The growth was extremely vigorous, the bunches fine and evenly swelled; and the circumstance was not thought at all strange, but it was considered that, if all the rods were in different temperatures, as good a succession of Grapes might be obtained as if separate Vines were employed. This seems feasible enough, if we disregard the roots, and imagine the supply of sap to be as much under our control as that of water in pipes of different kinds. We can form a tolerably correct idea of how far organisable sap will maintain growth by watching that of a freshly-planted deciduous tree. It will start apparently as strongly as if the roots had been undisturbed, but will suddenly come to a standstill, and, in that condition, have to wait until fresh roots are formed to enable it to make further progress. In the case of the Vine, however, the growth was carried on apparently without any check, for, by the time the organisable matter in its different rods had become exhausted, the roots were ready to maintain growth, and doubtless did so.

J. GROOM.

LATE-KEEPING APPLES.

THE summer and autumn of 1874 were so dry and warm, that they had the effect of ripening the late varieties of dessert and kitchen Apples better than has been the case for many years past. The soil in the kitchen garden here is of a very adhesive nature, with a red clay sub-soil, so that in wet cold summers and autumns Apples never ripen properly so as to keep well. I have, however, now in the fruit-room the following varieties of dessert Apples, all good-sized specimens and well coloured, namely:—Court-Pendu-Plat, Old Nonpareil, Fearn's Pippin, Golden Harvey, Keddeston Pippin, a delicious little Apple; Lamb Abbey Pearmain, one of the very latest keepers; Reinette van Mons and Reinette du Canada, both very large and good late dessert kinds; and Sturmer Pippin, which is one of the most valuable late Apples that can be planted, both for flavour and for being a sure bearer. The Calville Blanche, from small horizontal cordons planted on the bottom of an east wall, is another delicious Apple here, and keeps well; it is likewise one of the very best to be eaten by invalids, as it is one of the most melting kinds known. Of kitchen Apples, the kinds which are in best condition here, in the same fruit-room with the above, are the following, namely:—The Alfriston, a valuable large Apple, and very productive; this sort and the French Crab can be kept in a good fruit-room for two years without the fruit shrivelling much; the Brabant Bellefleur, another large and good-keeping kind; and Dumelow's Seedling, or Wellington, an excellent sauce Apple, with a brisk acid flavour. The Bess Pool is a finely-coloured sort and late keeper, but the tree is only a shy bearer. The Bedfordshire Foundling and Rymer are both excellent late keepers; and Allen's Everlasting is the latest keeper of all and is like the Sturmer Pippin in shape and flavour. In the above list of late dessert and kitchen Apples, I believe there will be found as good a selection as can be planted, where very late-keeping varieties are desired. In planting new orchards, too many of the early and mid-season sorts of Apples are in general planted, and there is produced a glut of fruit that will not keep, and which is not nearly so valuable for use or for market, as the late-keeping kinds.—WILLIAM TILLERY, in "Florist."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Souvenir du Congrès Pear.—Those who like Pears with a musky flavour, like William's Bon Chrétien, may note that this Pear has already obtained much praise, both on the Continent and in America. It is one of the largest of the dessert Pears.

Plants for the Back Wall of a Cool Vinery (H. L. B.).—You do not say whether frost is excluded or not. If frost is kept out, Camellias, Oranges, white Brugmansias, and the blue Plumbago capensis, are as good plants as any for such a situation.—R. G.

Ficus Parcellii.—A small plant of this, growing in a 4-inch pot, showed three fruit, but two dropped off. There is now one fine fruit measuring seven-eighths of an inch in diameter, with a foot-stalk half an inch in length. The variegation of the fruit is in stripes of green and white. Has this plant ever fruited in this country before?—RICHARD NISBET. [A plant of it bearing fruit was shown at the last Crystal Palace exhibition by Mr. B. S. Williams, of Holloway.]

Young Chaffinches and the Gooseberry Grub.—That excellent observer, Mr. Doubleday, of Epping, informs me that a brood of young chaffinches will soon clear a Gooseberry bush from grubs. It is, therefore, the interest of gardeners to encourage chaffinches in the breeding season, instead of taking so much trouble to destroy them or frighten them away.—EDWARD NEWMAN, in "Field."

CUPRESSUS LAWSONIANA.

TWENTY years have elapsed since this Cypress was introduced into this country. The horticultural and arboricultural world has had full time to make up its mind as to its merits, and we presume there will be little dissent if we call it the Queen of the Cupresses, and place it at the head of all those that are cultivated in the open air in this country. It has a grace and elegance peculiar to itself; it is perfectly hardy everywhere throughout Britain, has a flower to which none of the others approach in beauty or brilliancy, bears seed freely, and, besides all this, grows to be a large tree, and furnishes valuable timber. It was first described and figured by Mr. Andrew Murray, in 1855, from specimens that had been forwarded to him by his brother, Mr. William Murray, of San Francisco, being part of the produce of an expedition he had made to Scott's Mountain, in the north of California, where he found the tree growing over a waterfall, and described it as the finest and most elegant tree he met with in his whole expedition. Unfortunately, on that occasion, the trees he saw were not bearing much fruit, and only a few seeds accompanied the specimens. These were handed to Mr. Charles Lawson, of Edinburgh, after whom the species was named. From these seeds a few plants were reared, which are still growing in the Lawson Company's nursery at Edinburgh, and are the oldest trees of this Cypress in Europe. Its value was at once recognised; and Mr. William Murray made a second expedition for the express purpose of obtaining a good supply of its seeds. A tolerable quantity was procured, which was disposed of to Mr. Waterer, of Knap Hill; and from that source the great proportion of the trees of any size now growing in Britain have been raised. Subsequently, large importations of seed, from various sources, have been received in Britain; and, as the seed grows readily, there has been no need to resort to the practice of multiplying the species by cuttings or grafts, so that those who possess this beautiful species may, in almost every instance, rest satisfied that their plants are seedlings and not worked plants. At the time when this Cypress was described, nothing was known of its flower. Naturally, when people go seed-collecting, they prefer the autumn, when a better harvest awaits their labours than if they went in spring; consequently the flower not having been found could not be described. But the flowers of other Cupresses being all of one type, it was naturally thought that it would not differ materially from them. They have all a small insignificant flower of a dirty drab colour, and it never occurred to anyone that a species might exist which had a flower the colour of a soldier's coat. Such has turned out to be the case, however. Curiously enough, its first flowering occurred on a somewhat interesting occasion. Our readers may remember that a few years before his death Lord Palmerston paid a visit to Edinburgh. At that time Mr. Charles Lawson was Lord Provost of that city, and he would have been less a man of business than he was had he not seized the opportunity to take the Prime Minister over his nursery. Many were the novelties and rarities he had to display, but none of them were more beautiful, or interested Lord Palmerston more, than this Cypress the first raised plants of which had that very morning burst for the first time into bloom. Those of our readers who have not seen it may judge of its beauty from the accompanying plate. A few years after the introduction of this species, Dr. Kellogg, of San Francisco, described, under the name of Cupressus fragrans, another species, which he considered to be very close to, but distinct from, Cupressus Lawsoniana. This he obtained from near Port Orford, in Oregon, where it grows in abundance, and where it is known by the local name of the Port Orford Cedar (Cedar being, as our readers know, the American appellation for Cypress and Juniper). A plank of this Port Orford Cedar was at that time exhibited in San Francisco as a curiosity for its beauty. By-and-by seeds of authentic specimens of Prof. Kellogg's Cupressus fragrans were received in this country; but, when they came up, our botanists were unable to discover any difference between it and Cupressus Lawsoniana either in foliage or fragrance; still, as Prof. Kellogg was known to be an excellent botanist, they reserved their judgment until they should see its flower and fruit. Of course some years elapsed before this took place, but "time and the

hour wear out the longest day," and at length it flowered, first in the garden of Mr. Isaac Anderson Henry, near Edinburgh, and when the flower was seen it was thought to settle the matter in favour of Dr. Kellogg's *C. fragrans* being a distinct species, for it was yellow instead of scarlet. Botanists accepted the situation and admitted the species; but, ere long, a new change came over the spirit of their dream—other plants of *Cupressus Lawsoniana*, as to whose specific identity there was no doubt, began to flower, and it was then discovered that their colour was not constant, some plants bearing scarlet flowers and others yellow. There thus now seems no reason to doubt that Dr. Kellogg's species is identical with *C. Lawsoniana*, and the explanation of his error has been found in the extreme variability of *C. Lawsoniana* within certain bounds. Not only do the flowers differ in colour in different individuals, as we have described, but the growth, habit, and colour of foliage also vary in a remarkable degree. We believe that no seed bed of this species has ever yet been made which did not produce a number of notable varieties. Many of these have been picked out by nurserymen, and have been propagated by grafting and cuttings and widely distributed. We have golden variegations and silver variegations of several degrees; we have some kinds glaucous, and others green; some so mealy as to appear all frosted with silver or hoar-frost; others almost entirely destitute of this mealiness. Generally the habit of the branches is drooping, but some have been found growing as straight and narrow as an Irish Yew, others wide and spreading, but all bearing one common stamp, which prevents anyone doubting the species to which they belong. Specimen plants of this species have already reached considerable dimensions in Britain, and these show that, on the whole, its habit is close and spiry. It should reach 60 feet in height, and already we have plants of it upwards of 20 feet.

ANDREW MURRAY.

SAVANTS AND BOTANY.

A BRISK shower having driven me in from the garden, I sit me down quietly then in my study, and amuse myself with a species as curious as any of those we shall have opportunities of observing in either your voyage or mine. I propose saying a little about savants. You cannot but remember that smiling portion of your life, full of gaiety, sports, and affections—I mean childhood; that childhood always too soon given up to pedants, who aggravate children for ten years, in order to render them aggravating for the rest of their lives. Represent to yourself one of our school play-hours: all those open, ingenuous, cheerful countenances; these engaged in running and jumping, those with their kites, others in throwing and catching balls, and others, again, skilfully striking marbles with other marbles from a great distance. Recreation is the true education that belongs to this age; by it we become healthy, vigorous, active, and brave. But the fatal hour has struck. A man, with black clothes and a yellow visage, appears in the court. Everything becomes silent, everything stops, everything is sad. The sports of boyhood must all cease. And why? No doubt, for the sake of learning a trade, an occupation; to assure beforehand the independence of the whole of their lives. Not at all. There are amusements for a riper age as well as for childhood. Youth has no amusements; it despises them, it does not want them—it requires happiness. Childhood in no wise desires other ages to partake of its amusements. Youth would be furious if others wished to take away a portion of its felicity. But mature age insists upon having partakers of its amusements; which arises from the circumstance of these amusements being very tiresome. In fact, these said amusements consist in nothing but reading and re-reading, for the hundredth time, the same Latin and Greek books. For my part, I cannot see why each age should not be left in the free enjoyment of its own pleasures, or why children should be tormented during the whole of their joyous age, by being taught a game which may amuse them at an age they are not certain of attaining. I cannot see why they should be forced to admire what they don't understand; why an entirely literary education should be given to people who are destined to be dispersed through all the conditions of human life; or why literary studies should be confined, during ten years, to the learning of the only two languages that are never spoken. Jean Jacques Rousseau knew but very little Latin. I have no need to tell you why Homer did not understand Latin at all. That which savants do with regard to children, they do with regard to everything they come near. They render everything wearisome, dry, stiff, and pretentious. They cannot leave flowers

alone—they put them in starch. See a savant enter a smiling meadow or a perfumed blooming garden; listen to him: you would take a disgust for both meadow and garden. They began by forming for those graceful things called flowers three barbarous languages, which they afterwards mixed, in order to compound one still more barbarous; then every savant brought his little contributions of new barbarisms, as was done among the ancients to those heaps of stones placed by the roadsides, to which every traveller was obliged to add a pebble at least. I was about to write, at hazard, such of the words of this language made by these gentlemen as occur to me. But you would not only say, it is sad work to see flowers—that festival of the sight, as the ancient Greeks call them—thus treated; but I am sure you would not read two lines of them; therefore, I will let you off with half-a-dozen—mesocarps, quinqueloculars, infundibuliform, squammiflora, guttiferas, monocotyledons, &c. &c. &c. Have you enough? You will never make a botanist; you would have to store your memory with an endless nomenclature like the above, with the satisfaction of knowing that the learned are adding to it daily, and that when acquired you had not gained the name of a single flower. As to the names of flowers, look, at the foot of that wall, at these bunches of Mignonette or Reseda. Linnæus, who fully played his part in the barbarisms, but who considered flowers in a friendly light, and who, of all savants, has least ill-treated them—Linnæus said that the odour of the Reseda was ambrosia. Contemplate, while you can, its green and fawn-coloured spikes, inhale its sweet odour; for here comes a savant—there comes another—the Reseda is about to be transformed! In the first place, there is no such thing as odour. Botanists do not admit of odour. For them, odour signifies nothing, nothing more than colour does. Colour and odour are two luxuries; two superfluities of which the learned have deprived flowers.

Our savants are desirous that all flowers should resemble those which they dry in their herbals—horrible cemeteries, in which flowers are buried with ostentatious epitaphs. One of these savants looks at the plants, and says, "That is a Capparis, of the family of the Capparidaceæ, without stipulæ. The petals of the corolla alternate with the sepals of the calice; the filaments are hypogenous; the pistil is stipitated, and formed of the union of three carpels, the ovules attached to the three trophosperms; its seeds are often reniform, and have an endospermis—" "Gently! gently!" cries the other savant; "the Reseda is not a Capparis. The Reseda is an Euphorbia, according to Lindley, and a Cistus, in my opinion. The calyx is a common involucre; the ovary globular, seldom unilocular; the seeds are enveloped in a fleshy endospermis." "I admit the endospermis," replies the other savant, "and I allow that it is fleshy; but I maintain that the Reseda belongs to the Capparaceæ. I will further say, that it shows but little of a botanist to make an Euphorbiaceous plant of it." But let us stop! We should tear our sweet Mignonette to tatters. Listen to a savant upon another subject. He is speaking of the Marsh-mallow, a plant with round leaves and rose-coloured blossoms. Listen! "The calyx is monocephalous; the anthers are reniform and unilocular; the pistil is composed of several carpels, often verticillated; the fruits form a plurilocular capsule, which opens in as many valves as there are monosperm, or polysperm cells; the seeds are generally without endospermis, with foliaceous cotyledons." You understand nothing of this, though, perhaps, if you have an extraordinary verbal memory, you may retain some of the words. Then request the savant to tell you something about the Baobab. The Baobab, or Adansonia is the largest tree in the world; it may be taken at a distance for a forest; its trunk is often a hundred feet in circumference; it is asserted that some exist in Senegal that are over five thousand years old.

Hear the savant give a description of the Baobab:—"The calyx monocephalous; the anthers are reniform and unilocular; the pistil is composed of several carpels, often verticillated; the fruits form a plurilocular capsule, which opens in as many valves as there are monosperm and polysperm cells—" You stop the savant. "I beg your pardon, learned sir; it is of the Marsh-mallow you are speaking, or, at least, you said just the same of the Marsh-mallow but an instant ago." "Marsh-mallow or Baobab," replies the savant, "it is, for us, absolutely the same thing; we do not observe those differences which strike the vulgar, of which the dignity of science will not allow us to take notice." Savants acknowledge neither size, odour, colour, nor flavour: with them the Plum tree is a Cherry tree, the Apricot is a Plum; these very men, who, in other cases, give ten names to the same plant, call all these *Prunus*; the Almond tree and the Peach tree have but one name between them—*Amygdalus*. And then you know what charming names the pretty flowers of our field have received, no one knows whence, except from their own sweet nature; they know nothing of Paquerettes (Easter Daisy); Marguerites (the prettiest name for Daisies); Vergiss-mein-nicht (Forget

me-not). Marguerites and Paquerettes are Asters; and the pretty Forget-me-not, with all its delightful associations, is loaded with the name of *Myosotis palustris*. The rain has ceased, the sun has dispersed the clouds, and makes the drops on the leaves glitter like so many diamonds; the drooping branches recover their natural position; a linnet sings in a Hawthorn. The savants may settle their disputes by themselves.

ALPHONSE KARR.

THE LIBRARY.

INSECT DEPREDACTIONS.*

NORTH AMERICA would appear to have suffered in an unusual degree during the past year (1874) from the ravages of one or two of its insect pests. We have just received the above-mentioned "Annual Report," published by Mr. Riley, the able state entomologist of Missouri, and we learn from it that the ravages of the chinch bug and the Rocky Mountain locusts had exceeded anything that had taken place for many years. Of the devastation and ruin caused by the latter the public have already had some glimpses by the occasional notices in the newspapers and applications for assistance to support those whose crops have been ruined by them; but of the mischief done by the former little notice has yet reached this country. It appears from Mr. Riley's data, nevertheless, that although the amount of human suffering occasioned by the locusts may have been greater than that by the chinch bug, as was natural in a newly-settled country, whose population almost entirely depended for subsistence on their crops, the pecuniary loss inflicted by the latter must have been much the larger. The range of the locust is great, but it has a limit. Their natural breeding-place is the Rocky Mountains, and from them as a starting-point they have always to take their flight, and the flight does not reach much beyond the Missouri River. If, like the Colorado beetle, they could start next year from the farthest point at which they arrived, they would reach the Atlantic in a couple of years. But it appears from Mr. Riley's report that, although they lay their eggs at the farthest point they reach, and young locusts are hatched from them, yet they do not thrive—the climate or country does not suit them, and they all die out in two or three years. This is the experience of former invasions, so that Mr. Riley seems warranted in holding that the extent to which their ravages may extend will never be far beyond that of the utmost flight of fresh swarms from the Rocky Mountains. Mr. Riley has mapped out the limits to which they reach, and his assurance that they will not pass far beyond them has been of much importance to the state to which he belongs, for the scourge had almost stopped emigration to Missouri, although great districts of that state are beyond the range of the locust, and the publication of the ascertained limits of the scourge has again restored confidence, and emigration has been resumed. The fact that its range is limited, and that a large portion of the country over which it extends is either altogether unsettled or only sparsely inhabited, greatly reduces the amount of mischief done; but it has still been enormous. The money-loss caused by the locust last year is estimated at not less than ten million pounds sterling. The chinch bug, on the other hand, seems to spread without restraint wherever cereal crops are cultivated. Consequently, instead of a mere strip of territory, of say, 500 miles in breadth to the west of the Rocky Mountains, being overrun by it, it may reach from the Atlantic to the most western limits of cultivation. In point of fact, it has, of late years, been chiefly injurious in the western cultivated regions; but it has not always been so, and perhaps has originally spread from the east to the west. It does not appear at any time to have been equally destructive all over the Union. It is, therefore, very difficult to estimate the actual amount of loss occasioned by it in any year; at least, it would require a much more complete machinery for doing so than the United States as yet possesses. But we can take individual states that happen to have the necessary machinery, and from them form some faint idea of the total general loss that has been sustained. Mr. Riley gives an estimate of the

loss in Missouri on the three staple crops of Wheat, Corn, and Oats, and makes it amount to nearly five million pounds sterling. Ten years previously (1864), the estimated loss through the chinch bug in Illinois was nearly fifteen millions sterling, and, in 1871, in it and the neighbouring north-western states upwards of six millions sterling. These astounding figures will, we are sure, occasion as much surprise to American readers as to European. Many a man knows that he himself, and some of his neighbours, have had only half a crop, but it never occurs to him to think what an enormous total the loss would amount to if the individual losses sustained by every one in the like predicament throughout the length and breadth of the North American Continent were all to be brought together. It is here that we see the usefulness and advantage of the American system of appointing state entomologists for different districts. It is by some supposed that the chief duty of a state entomologist is to tell to the agriculturists and others who apply to him the names and habits of the insects they send him and the most approved means of destroying them or preventing their increase. This is, no doubt, part of his duties; and, in a new country, where competent entomologists are few and far between, no doubt an important part, but it is a very minor one where entomologists abound who know as much of the subject as the state entomologist himself, and could easily be got to supply the information were he non-existent. Any obliging entomologist would do that; but no entomologist, however willing, would—unless it were his duty, and he were paid to do it—undertake to send circulars year after year in order to obtain statistics of the extent and limits of the mischief committed by any particular insect which might show itself, and conduct an extensive correspondence regarding it; or would travel from district to district to study it on the spot, or take the labour of obtaining and sifting information from each district, showing how much money had been lost in each, or conduct troublesome and costly experiments to find the best way of dealing with the soil. If there had been no state entomologist in Missouri its inhabitants would have remained in ignorance of the extent of the dire mischief eating into the vitals of their agriculture, which has been revealed by the extensive correspondence summarised and published in the reports of Mr. Riley and his brother state entomologists. The knowledge of the existence of an evil is the first step to its cure. Do we in our own country pay sufficient attention to this? Can anyone tell us how much we lose annually from the attacks of the wire worm, Wheat fly, surface grub, Turnip fly, or any of the thousand and one insect pests that prevail amongst us? Mr. Riley, with excusable complacency, points to the pre-eminence of America in this respect. He says—"There are yet, and doubtless ever will be, those who, dwelling in cities and familiar only with such lectularious insects as cause them bodily inconvenience, have little appreciation of agriculture or of entomology in connection with it; and consider the study of 'bugs,' as they contemptuously call everything that creeps, a fit subject for ridicule. When, however, a single insect, like the chinch bug, filches four millions sterling in a single year from the pockets of the cultivators, and reduces in so much the wealth of the state, even such persons may be brought to admit that any study having for its object the reduction of this immense loss is not necessarily contemptible, small as the objects may be with which it deals. Fortunately such persons are becoming fewer and fewer, and the following pages bear witness to the fact that not only in several states in our Union, but in several countries of the Old World. In monarchies, empires, and republics alike, the authorities have manifested a remarkable appreciation of economic entomology. We have during the year witnessed Australia and New Zealand discussing and attempting the introduction from Europe of aphid parasites to check the alarming increase of those plant pests, and of bumble bees, to enable cultivators to grow their own Clover seed. We have seen France increasing her premium for a *Phylloxera* remedy to 300,000 francs, and considering plans for the destruction of the pest by constructing an irrigation canal to supply 60,000 acres. We have seen Massachusetts memorialising her legislature to pass 'an Act for the destruction of insects injurious to vegetation,' while some of our own state legis-

* "Seventh Annual Report on the Noxious and other Insects of the State of Missouri," By C. V. Riley, State Entomologist. 1875.

latures have been convened in special session to consider means of relieving the sufferers from insect ravages, and several European governments have, with forethought and wisdom, taken such measures as seemed best to prevent future injury from still other insect pests." We have occupied so much space in dealing with the generalities suggested by Mr. Riley's "Report" that we have left ourselves none for details, but we may on another occasion revert to them.

FERNS.*

THIS is undoubtedly the handiest and best book of reference of which the gardener or amateur can avail himself in the study of Ferns. It contains short technical descriptions of about 2,600 species; yet the technicalities and abbreviations, which must necessarily be employed in a work of reference, are such as anyone fond of Ferns could easily master in a few hours. The first edition was published in 1868, and there has been but little alteration since, except the addition of about 400 new or rare species, and a newly-arranged index, which may be obtained separately, and which is of itself useful as regards nomenclature, or in facilitating the exchange of specimens. Mr. Baker takes a broad and comprehensive view of the species, and has done much towards simplifying names and classification. The volume is illustrated by nine lithographic plates, beautifully drawn by Mr. Fitch, and these will be of great service to all lovers of Ferns, as they show at a glance the differences which exist between the primary divisions of the great Fern family. Altogether, the book, as we have said, is an excellent one for purposes of reference, and it is one which ought henceforth to find a place in every garden library.

THE TOMB OF THE TRADESCANTS.

THE following lines were, in 1796 (and probably still are), on the monument of the Tradescants at Lambeth:—

Know, stranger, ere thou pass, beneath this stone
Lye John Tradescant, grandsire, father, son;
They gathered what was rare in land, sea, air,
As by their choice collections may appear;
Whilst they (as Homer's Iliad in a nut)
A world of wonders in one closet shut;
These famous antiquarians, that had been
Both gardeners to the Rose and Lily Queen,
Transplanted now themselves sleep here—and when
Angels shall with their trumpets waken men,
And fire shall purge the world, these hence shall rise
And change this garden for a paradise!

Their collection of rarities was purchased by Elias Ashmole, and placed in his museum at Oxford. B. S.

Mummy Corn.—"Some twenty-three years ago Dr. Abbot, of Egyptian antiquity fame, presented my father, the late Dr. John W. Francis, with some grains of corn which he had himself taken out of a mummy. They were planted in our garden in Bond Street, and well do I remember the anxiety exhibited about the growth of this grain, which had been concealed for 3,000 years. In due course of time an ear appeared and ripened on the stalk. It resembled in many respects the Virginian corn of the present day. This proves that corn existed in Egypt before the discovery of America." The above, says the "American Agriculturist," is copied out of a very queer pamphlet, just published, entitled "Curious Facts concerning Man and Nature," by a physician. When the author has been in Egypt, and see how ingenious and active the people are in preparing "mummy grain" and other articles, for which both Maize and Doura are conveniently at hand, he may be less confident about the existence of Maize in Ancient Egypt, and the germination of any sort of grain 3,000 years old.

Art and Criticism.—It would be a great thing for English Art if in default of getting rid of Royal Academicians we could somehow abolish the preliminary banquet at the Royal Academy. Both institutions are bad, but in its effect upon public taste perhaps this is the worst. When the Prince of Wales remarks that everyone with artistic taste "must agree with him" that the present exhibition is as good as any of its predecessors, a great many ignorant persons are misled into the belief that the statement is true; and when Mr. Disraeli announces that the special triumph of English painters at the present time is in the department of imaginative painting, the public which has faith in Mr. Disraeli feels bound to discover in the exhibition those high qualities that are not by any means to be found there. A poor

* "Synopsis Filicum: a Synopsis of all Known Ferns." By the late Sir W. J. Hooker and J. G. Baker. Second edition, pp. 559. London: Hardwicke, 1874.

Academy would not in itself be such a disastrous thing for the interests of English Art if it were recognised as poor, and if there were enough critical courage and discernment to point out clearly how deplorable is the failure and how great is the necessity for increased and profounder study. But when we have on the one hand, a body of men who are certificated for life as painters of genius, and, further, when these same men invite every year Princes and Archbishops and Prime Ministers to confirm their reputation by foolish flattery and ignorant applause, there is very little chance for those who studiously watch the course of Art progress to get a hearing for a careful and real judgment.—"Examiner."

TREES AND SHRUBS.

WEIGELAS.

OF the numerous varieties of Weigelas a large number, although very beautiful, have disappeared, and scarcely half-a-dozen are to be found together, even in the very best horticultural establishments; our access to these, however, has enabled us to give a description of the following kinds:

Weigela rosea.—This variety was introduced from China by Fortune, and was described and named by Lindley. It forms a bushy plant, and has very dense foliage. The buds are of a deep rose, whilst the flowers are flesh-coloured in the interior but shading into the former colour, and here and there a flower is met with, the interior of which is pure white.

W. rosea variegata.—This shrub is somewhat more delicate than its type, with numerous branches, which are proportionately slender. The leaves also are smaller, and are edged with pale yellow. The buds are light-rose in colour, and the corolla regular; white in the inside, shading to a flesh-colour, and on the outside of a more or less deep rosy-tint. It flowers profusely.

W. Desboisii.—This is a very vigorous plant with large branches, having reddish-brown bark. The leaves are very large, as well as the flowers, which are regular and smooth, of a deep rose, or rather red colour, lightly marked in the inside; upon a portion only of the throat and upon a few flowers a long yellow stain appears, and this, most frequently, is altogether wanting. Towards the latter end of the blooming period all the flowers are of a deep blood-red colour, so that, at the time when so many varieties have lost all their beauty, *W. Desboisii* is still extremely ornamental.

W. mutabilis (var. Isoline).—This plant, which has some affinity with the variety *Stelzeneri*, is distinct even in appearance. It is very vigorous, and has long branches. The leaves in colour are a deep, dark green, and the buds are yellow and, towards the top, a light rose. The flowers are very numerous, appearing from the end of April, when they are light yellow; later on a bright rose; and finally a purple-violet in colour.

W. Isoline is easily distinguished from the other varieties by its dark appearance, and by its leaves, which are longer than those of the others. It is a vigorous plant, and the earliest of the entire group.

W. amabilis is a plant of medium vigour. The flowers are of a beautiful light rose colour, and do not change. This plant is extremely floriferous, and often assumes a climbing habit, especially when it is placed in soil that is rich and damp, and its growth is not interrupted.

W. nivea.—This is a dwarf plant, with spreading branches—some of them often lying upon the ground—and a light green bark. The leaves are a pale green colour above and silver-white beneath. The buds are flesh-coloured, and the flowers of a pure white, and never become coloured; the corolla is short and regular, and not crumpled. This variety, in all its characteristics is very distinct, and can never be confounded with any other, for it never exceeds comparatively small proportions, is somewhat late in flowering, which commences in the middle of May and lasts a considerable time.

W. amabilis (Van Houttei).—Has branches that are very robust and upright, and subsequently become curved. The flowers are large, very regular, and flesh coloured, or nearly white, inside, which changes to a spotless rose; on the outside they are yellowish-red. The plant is a vigorous and well-furnished one, having large cylindrical buds. It blooms for a considerable period.

W. amabilis alba.—The branches of this variety are wide-spreading and far apart. The buds are of a very soft rose colour, swelling towards the summit. The flowers are well separated from one another, of a milky whiteness, or flesh-coloured, on the inside, and light rose-coloured on the outside. This plant is very vigorous and very ornamental from the beauty of its flowers, which are often of different colours at the same time, some being nearly pure white, others rose, and others again nearly red. Throughout the earlier part of the blooming period the white colour predominates; later on when the hot weather has commenced, nearly all the flowers are rosy.

hued, and sometimes even red, except in the case of new blooms, upon which the flowers are white, or light flesh-coloured, which rapidly gives place to the pink tint. The blooming period is unusually long.

W. floribunda.—This variety is one of the most remarkable from the soft rose of its flowers, which are excessively numerous, and give to this plant a peculiar beauty. The leaves are thick and woolly, and the blooming period of the plant a long one.

W. arborea grandiflora.—The general appearance, the growth, and the blooming of this species, unite in making it a very distinct plant, which cannot be confounded with any other. The branches are robust, long, and wide-spreading; and the buds are long, of a greenish-yellow colour, and lightly red at the summit. The flowers are yellow, sometimes more or less rose-coloured, and regular; the corolla is very wide. *W. arborea grandiflora* is very different from all its congeners. It differs in aspect, and in the colour as well as the disposition of the flowers. The plant also flowers much later than the rest, and the blooming period is proportionately prolonged. This plant is also remarkable for the diversity of colours presented by the flowers. Thus, at the very beginning of the flowering season, they are a yellow, inclining to green. Some of them soon assume a rose tint, then others; till at last the yellow tint is the exception; and flowers of a light green, more or less rose-coloured, and sometimes of a dark purple, appear upon the same branches.

W. arborea purpurata has vigorous branches, which are erect and wide spreading. The leaves are large in dimensions, and the flowers are large, regular, and of a deep red tint over all parts, even in the interior, except in certain flowers where the divisions are a little clearer and not stained. This plant is handsome when its flowers are freshly blown, but they have the drawback of fading early.

W. Groenowegenei.—This is a very vigorous shrub, the buds of which are a deep red. It has large flowers, which are rose-coloured inside the tube, and marked on one side, as well as upon one of the divisions, with a large yellow spot. This plant, named after a Dutch horticulturist, M. Groenowegen, is remarkable for its being extremely floriferous. Of all the varieties it bears the largest, but the least decided, yellow spot on the interior of the flowers. When the hot weather comes the flowers are much more highly coloured and ordinarily more regular.

W. multiflora.—This is a bushy compact shrub, of medium growth. Its leaves are elliptical, much attenuated at the base, and hairy. The inflorescence is upright and compact. The buds are deep red, large, and sub-angulous or wrinkled. The flowers, which are very numerous, are borne upon short thick spikes, and are of a deep red colour, but not spotted.

W. graciliflora.—This is a tolerably vigorous-growing shrub, with spreading branches. Its leaves are elliptical, and the inflorescence loose and short. The buds are striped bright rose, and the flowers, which are scattered, are of a pale rose-violet colour, and last in perfection but a very short time.

W. excelsa.—This is one of the most ornamental species of the genus, and it is also one of those that grow the tallest. It is vigorous, forming an erect bush often several yards in height. The leaves, which are oval elliptic, are slightly plaited, and of a dark green colour. In colour the buds are a vinous red, lightly touched with lilac. The flowers are at first green, but subsequently become variegated with rose, and they withstand heat better than those of other *Weigelas*.

The following hybrids between *W. rosea* and *W. multiflora* were raised at Nancy by M. Lemoine:

W. Hendersoni.—This is a robust plant, with elliptic and acuminate leaves. Its buds are very pale red, almost ash-grey; flowers vinous-red, and regular in form.

W. Lowi.—The branches of this variety, which are slender, have coloured bark. Its leaves are elliptic in shape, and downy on the undersides. In colour, the flower-buds are a greyish-red; the flowers themselves small and of a deep red exteriorly, and interiorly of a lighter shade, more rarely rose; with short, regular divisions.

W. Lavalleyi.—A very vigorous shrub, the shoots of which are thick, and greenish-red in colour. The leaves are broad and regularly cordiform. The flowers, which are regular in form, are of a blood-red colour, with short, spreading divisions. The style, large and projecting.

W. Kermesina.—This is a spreading slender shrub, the flower-buds of which are highly coloured, and the flowers, when open, of a brilliant blood-red colour.

W. carminea.—This is a medium-sized shrub, the bark of which is a deep red colour, and the leaves slender and elliptic in shape. The flowers, which spread but slightly out, are of a purple-red in colour, and the style protrudes beyond the corolla.

W. Lemoinei.—This is closely allied to the preceding kind. Its flowers, which are of a very deep tawny red, are regularly tubulous, opening out but slightly at the summit. This, owing to the abundant way in which its flowers are produced, and its very deep colour, is a highly ornamental variety.

Propagation.—*Weigelas* are increased by means of layers, cuttings, and seed. Cuttings are struck under cloches, and in cold frames, any time after July, using half-ripened shoots for the purpose. The soil should be open, or rendered so by the addition of sand. The following is, however, the speediest method of increasing the stock of these plants. Get a *Weigela* in a pot, and, in January or February, place it in a forcing-house to induce it to push into growth. As soon as the young shoots reach an inch or two in length, remove them and strike them in sandy peat in very small pots beneath a cloche, where they will root in a few days. This should be continued as long as shoots can be obtained, and, when well rooted, the cuttings should be hardened off and set out of doors, re-potting them as they need more root-room. Cuttings may also be made of the ripe wood, as in the case of Gooseberries and Currants.

Seed Sowing.—The seed of *Weigelas* should be sown in spring, either in pots or pans filled with sandy peat. It may also be sown in the open-air in well-prepared ground. In all cases, the seeds should be but slightly covered, for, owing to their smallness, they will not germinate if buried too deeply. If sown in the open air, they should be shaded with branches, &c.

Pruning.—This merely consists in cutting off dead wood, and removing any too straggling branches, operations which may be effected in spring, before flowering-time; but, if it be necessary to prune more severely, it should in that case be done soon after the flowering season, as when the flowers develop upon the one-year-old wood, it is necessary to give the latter time to form if it be wished to obtain blossoms the following year, exactly as in the case of Lilac or Guelder Rose. *Weigelas*, like most other plants, vary much when raised from seed, and I should not be astonished if, in this group of plants, there was but one typical form, and, consequently, that the several varieties figured and described by Siebold and Zuccarini, are simply garden varieties. This is all the more probable, inasmuch as, at the time when the authors wrote the "*Flore du Japon*," they could only penetrate into certain localities of that country, and the majority of the plants described and figured were furnished by Japanese, probably from gardens. Frequent sowings made of *Weigelas* justify us in putting forward this hypothesis. Last year kinds differing widely from one another were obtained, far more so than most of those that are considered as varieties. Some were of extraordinary earliness, which we hope to keep; these were covered with flowers at the age of three months. Some had variegated leaves, others were of a peculiarly dwarf habit, the leaves of which were only a quarter of an inch in size. If these characteristics can be fixed, these plants should be considered as species.—"*Revue Horticole*."

THE NAIL GALL OF THE LIME TREE LEAF.

THIS must be familiar to most of our country readers, who cannot fail to have noticed the Lime tree leaves studded on their upper sides with numerous erect excrescences, at first green, afterwards yellow, then crimson, and, when withered and dried, black, looking exactly as if a quantity of small nails or tacks had been driven through from the under side of the leaf. Various explanations have been given of the origin of such galls. By some they were considered cryptogamic growths, which the older botanists (Von Fries and Kunze) placed in a genus which they called *Erineum*. Most of the growths which they included under that head, however, have since been ascertained to be due either to hypertrophy or to insect action; and, notwithstanding the remarkable fact that they are sometimes confined to one tree, which would at first sight rather seem to point to some constitutional peculiarity in the tree, there is little doubt that the majority of them are caused by some insect; and as a response to any inference that might be drawn from their attaching themselves to one tree only, we may mention that although, as we all know, Oak galls are produced by insects which are provided with large wings, some kinds of them, at least, do not seem to like to leave their tree, and are to be found upon it year after year, and on no other. Thus, we know of only one locality, and one Oak tree on which the rare Oak gall produced by the *Cynips* named *Trigonaspis megaptera*, is to be found. In the same way as the common Currant Oak gall, and the Oak root gall, stick persistently to the same tree, so the species of small midges stick to the same place. The *Cecidomyia Pyri* year after year regularly destroys the young Pears on some trees belonging to a friend of ours, while his neighbours at no great distance escape. The occasional permanent restriction of a gall to one tree is, therefore,

not necessarily a valid argument against its being produced by insects. We have made this preface because it sometimes does occur that the nail gall of the Lime tree leaf appears year after year on the same tree without wandering to any of the neighbouring Lime trees. The view now generally adopted by entomologists is that the gall in question is produced by a mite—an opinion in which we cannot concur. We believe it to be the work of a *Cecidomyia*, or midge; and we ground our opinion (1) on the observation of Reaumur, which we shall quote; (2), on the fact that in America a gall almost identical in appearance is produced on the leaf of the wild Grape by a *Cecidomyia*. The reader will naturally wonder that there should be any doubt about the matter. There can surely be no difficulty in distinguishing between a mite and the maggot of a midge, neither is there; but the curious thing is that, when the gall is opened, as it has been by thousands of competent observers, nothing is usually found within it. We have ourselves often opened them, and examined the interior and the parenchyma below the gall, and never succeeded in finding a living thing. Some few observers have been more fortunate, and all that we have to go upon is their statements; and, as these are contradictory, we have to weigh the evidence, not as to credibility, of course, for no one doubts that, but as to the true meaning and value of what each has seen. Now the first witness is Reaumur, who comes before us with the

disadvantage of being nearly 140 years old; of being, of course, ignorant of all the knowledge acquired since his time, and of having possessed very imperfect microscopic appliances compared with those which every tyro can now procure; but also with the advantage of a thorough practical personal knowledge of his subject, and much ability and acute powers of observation. That his researches are still referred to as standard authority is a sufficient warrant for listening to him with attention. Writing in 1737, he says:—"We find on the leaves of the Lime some of these galls, which are probably due to extremely small insects; the leaves of that tree are often bristled, like a kind of harrow, by long galls, the shape of which has led me to call them nail galls. They have something the appearance of nails, of which the points are above and the head below the leaf. The comparison of these excrescences to small horns slightly turned would perhaps be still more just, because, besides that they are rounded, and that they terminate in a point like

horns, their interior is hollow. It is, nevertheless, filled to a certain extent by cottony-looking hairs, which proceed from the walls of the cavity. I have opened these galls hundreds and hundreds of times without finding anything in their interior, which has often happened to me because I set about it too late. I have subsequently examined the galls at an earlier stage, while they were still green, and have found insects in almost every gall examined. I never saw more than one in each, although there is an appearance as if they might be in company." (Reaumur perhaps here alludes to some of the galls being, as it were, double, or thicker than others, or two or three proceeding from the same base.) "These grubs are long; under a strong glass they do not appear thicker than the stalk of a small pin. They are yellowish, like the interior of the gall. What makes them more difficult to find is that they do not like to walk. I often saw one, and was uncertain whether it was a grub or not until it pleased to put itself in motion. It is towards the base of the gall that we found them. When the galls get old some opening or crack takes place, by which mites, and stranger insects, introduce themselves. I have seen, for example, mites, ensconced there." All this quite agrees with what we should expect were the insect a *Cecidomyia*, and the inference that it is one is supported, as we have already said by the Trumpet Grape gall of America, which is so identical in appearance to that of the Lime,

that, if the galls could be transposed from one leaf to the other, scarcely anyone would notice the difference. It is produced by a small midge or gnat, which was described under the name of *Cecidomyia vitis viticola* by Baron Osten Sacken in his "Monograph of the Diptera of North America" as an "elongated conical red gall 0.25 to 0.3 long, on the upper side of the leaves of the Grape." Mr. Riley, the able State entomologist for Missouri, had also determined it, and in relation to it speaks thus of the present gall. He says ("American Entomologist," II., year 1870, p. 113):—"Referring to this gall in a recent letter, Francis Walker, of the British Museum, informs us that an excrescence of a very similar form, but black in colour" (he should have said crimson, it is only black when dried) "occurs on the leaves of the Lime tree in England, but that the character of the gall maker has not been determined. A French naturalist has, however, detected mites in them, and we have little doubt but the galls are caused by these mites, for mite galls of somewhat similar form are common in many parts of this country on the Plum and Cherry." We do not suppose that the French naturalist here alluded to is Reaumur, but rather M. Dujardin, who in 1850 gave a description of a mite that he had found in these nail galls, under the generic name of *Phytoptus*, a contraction for *Phytocoptes*. We think, however, that the evidence in support of its being the gall

maker is very weak. In all cases that we know of where galls of a special and distinct form are produced, they are invariably the work of some specific insect, told off, as it were, for that special purpose. In other words, the same insect does not make two different kinds of galls, and the same gall is never made by two different kinds of insects, nor on two different kinds of trees. But Dujardin found his *Phytoptus* not only in the nail gall of the Lime leaf, but also in malformed and distorted buds of the Hazel. Other authors had previously referred these galls to mites, but their conclusion is open to the same exception that we have taken to that of Dujardin. Latreille described, and Turpin figured, the producer of the gall as a species of *Sarcopites*. Duges found the same mite in a similar gall on *Salix alba*, and he regarded it as a larval form of *Tetranychus*. Von Siebold next found the same mite among the hairs of some species of *Erineum*, and named it *Eriophyes*. To our mind there is in all this a want of that restricted and definite relation between the gall produced,

the plant on which it is produced, and the insect producing it, which is essential to the relation of gall and gall maker. An insect that is found at one time in the distorted buds of the Hazel, and at another in the galls of the Willow leaf, and at a third in the galls of the Lime leaf cannot according to our view, be the maker of all three. To this matter (says the "Field") we venture to invite attention. It may be, and no doubt is, too late for this season, but perhaps some of our readers may remember it next year; and if they then find the little yellow grub seen by Reaumur, all they have to do is to envelop a few of the growing gall-bearing leaves in muslin bags to catch the larva when it comes out to undergo its metamorphosis, if it proves to be one of those that do not complete them in their original nidus (which many do), and, in that case, putting them on earth, in a flower-pot covered by a small bell-glass, breed and catch the midges when they come out.

MAZES.

MAZES or labyrinths are more common in England than elsewhere, a circumstance attributable in some measure to the excellent way in which evergreens succeed with us. They are constructed either upon level ground or upon an artificial eminence, the summit of which may be occupied by a summer-house. They usually consist of plantations

Plan of an ancient Maze.

of shrubs, in the form of hedges, enclosing tortuous paths, which constantly lead the bewildered pedestrian back to the spot whence he started, or bring him to a barrier beyond which he cannot advance, and from which, therefore, he must of necessity retrace his steps. One alone of all these paths leads to the centre, and the difficulty consists in striking upon this. In general, stiffly-growing evergreen shrubs are used; often Yews, which, from the thickness of their foliage, and the ease with which they are induced to take a variety of forms, are well adapted to this purpose. The height of the hedge varies considerably, but is usually about that of a man. The essential point is that it should be well furnished with foliage, regular in form, and pleasing to the eye. If the labyrinth be placed upon rising ground, the height of the hedge must be so regulated as not to conceal from view the highest point that has to be attained, to gain which is at once the object of the walk and the resting-place. The labyrinth that we figure to-day is one which was designed by Claude Mollet in 1653.

The Chinese Cedrela.—This is a valuable hardy tree from the north of China; it was named and described by Andrien de Jussieu ("Mém. du Mus. d'hist. nat.," XIX, 255, 294), and its introduction has long been desired. Now it appears, that this has been accomplished. In 1862, Mr. Eug. Simon sent a tree from China to the Jardin des Plantes of Paris, and Mr. Carrière took it to be a new species of *Ailantus*, and published it as *A. flavescens*. The same writer now declares it to be the *Cedrela sinensis* of Jussieu, and therefore this tree has long been in Europe, though unrecognised. There is a specimen of it in the Jardin des Plantes upwards of 25 feet high, with a girth of trunk of about 20 inches, at 3 feet from the ground. It also exists in several nurseries, and is known in commerce as the Yellow *Ailantus*, which must give way to the correct appellation of Chinese *Cedrela*.—"Illustration Horticole."

Influence of the Scion upon the Stock.—Two plants of *Abutilon Duc de Malakoff*, which were raised from seed, and which had grown some 8 or 9 feet in height, were considered to be suitable stocks, to make into standards, upon which to engraft the weak-growing, pendulous *Abutilon vexillarium* (*mesopotamicum*) *igneum*. The grafts, which were put on at about 6 feet from the ground, took readily, and some shoots were left on the stock, in order to assist in drawing up the sap until the grafts became more fully established, when it was intended to cut them away. Soon after growth commenced, however, some faint signs of variegation became apparent, and the shoots were allowed to remain. The result is, that the whole of the shoots which have broken out near the grafts have become beautifully spotted, blotched and barred with yellow, the markings being similar to those which occur in the scion. The two forms growing together, and presenting such a wide contrast in the size and outline of their leaves, are very attractive and ornamental. These plants have now been established for upwards of twelve months, and have formed good round heads. Plants treated in this manner will produce a good effect through the summer and autumn months, either placed in sub-tropical beds, or used as single plants in sheltered places on the turf.—J. WEBSTER, *Gordon Castle*, in "Florist."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Jamesia americana.—This is now in flower in Mr. Ware's nursery at Tottenham. It is a white-flowered Rocky Mountain plant, allied to the *Hydrangeas*, and quite hardy.—Q.

Trees in Streets.—The "Birmingham Post" hears that it is proposed to plant trees in some of the open spaces in Birmingham, choosing, by preference, the districts in which the neighbourhood is most densely peopled. We have never visited a great town more wanting as regards trees, squares, or open spaces.

Barren Magnolia.—Your correspondent, "C. G." (see p. 498), is by no means the only sufferer from *Magnolias* not flowering. We have several large specimens here which, although fine healthy trees, have never been known to flower. I procured a few small plants of the Exmouth variety, and they flowered freely the first year after planting.—J. GROOM, *Henham Hall, Warrington*.

The Double Hawthorn Scentless.—The Hawthorn flowering has been exceptionally fine this year, and so continuous that even now (June 14) some of the kinds, such as double white and pink kinds, are still beautiful. The former is assuming a delicate pink hue, and becoming very pretty. It seems, however, that the double varieties have little or no smell, and, however beautiful they may be in appearance, we must confine ourselves to a limited number of them if we want sweet-scented Thorns in our hedgerows.—CHEVALIER.

An Old Sacred Tree.—The Cypress of Somma, in Lombardy, is said to be the oldest tree on record, dating from the year 42 B.C.; but at Anuradhapura, in Ceylon (noted for its ancient palaces), there is a Bo tree—a very famous object in connection with Buddhism—which, according to a writer in "Science Gossip," was planted 288 years B.C. It would have been blown down long ago but for a thick wall built round the trunk, and all its main branches are supported by pillars. The leaves that fall off are collected by the Buddhist priests every day, and are kept in a holy part of the temple. They are offered to their deity on festival occasions, also sold to the poor ignorant natives, who believe the money paid for these holy leaves will buy them the righteousness of saints. This tree is held in such reverence that it is often visited by numbers of pilgrims.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Asparagus Beds.—These, now that cutting is over, will be much benefited by a good soaking of manure-water; this, being a marine plant, enjoys salt, which, if it be added to the liquid at the rate of 2 ounces to a gallon, will materially assist *Asparagus* beds, especially such as have been long in bearing. Keep the beds quite free from weeds, which it is necessary in this case to remove by hand, as the use of the hoe would interfere with the plants. Beds that have been much cut should, at the present time, be encouraged by every means to make good growth, for on this depends their ability to keep up, in years to come, their producing powers, both as regards quantity and quality, in a satisfactory state. *Asparagus* often gets worn out much sooner than it otherwise would through suffering neglect after cutting has ceased.

Kitchen Garden.—The work here for the coming week will be of a routine character, and will consist of attention to the different advancing crops. Keep the hoe at work amongst bush fruits, so as to destroy weeds as they appear. It sometimes happens that there is negligence in this respect, under the impression that the bushes do not suffer from the presence of weeds as culinary vegetable crops do. So far as immediate effects go, this may be the case; but, wherever they are allowed to grow, they exhaust the soil much more than ordinary cultivated plants do; and to let any part of a garden become foul is simply a direct waste of the manure used, of which even bush fruit stands in need, although not to the same extent as vegetables. Amateurs will also do well to observe that if any portion of their garden, however small, be allowed to become a nursery for weeds, the seeds will be scattered by the winds in all directions, and will cause endless trouble afterwards; whilst the pleasure derived from the appearance alone of an orderly well-kept garden is worth consideration, and all the care that can be bestowed upon it. A clean garden, where every operation is carried out as soon as it requires attention, takes much less labour in the aggregate than one where things are continually behind; and in the operation of weeding this is more than usually apparent. In the southern counties, it is a difficult matter during this part of the season, unless the weather is very wet, to get a crop of Turnips up so as to escape the ravages of the fly which often cause a blank in the supply of this vegetable. Have a piece of ground in readiness, so as to sow as soon as rain falls, sowing in rows, as directed earlier in the season, and putting in a good quantity of seed to allow for those that may be destroyed by this active little beetle. When the plants are fairly above ground, if the weather becomes dry, a good practice is to water them well, and, whilst the leaves are wet, to dust over with soot—the fly does not like either the soot itself nor its smell—and a repetition of this kind of treatment will sometimes secure a crop; but, where the insect exists in great numbers, this is often impossible until the season is further advanced. It frequently happens that at the time of preparing the ground there may have been a scarcity of manure, of which some crops have not received a sufficient quantity. Where this has been the case, make up the deficiency by the timely application of liquid manure. This should take place at the middle stages of growth, after the plants have taken a fair hold of the soil and are growing away freely, and when strength will be imparted at the time it is most required. It is, however, necessary for amateur gardeners to be cautious in the use of manure-water; it must not be applied too strong, for plants, unlike animals, have not the power of rejecting the food that is given them, which, in a liquid state, goes direct to the roots, and is of necessity absorbed by them, even if their destruction is the result. If manure of a solid character, such, for instance, as fowls'-dung in a crude state, or guano that is lumpy and insufficiently broken, is dug into the soil, the case is somewhat different; the roots will not enter it, but will run in other directions to escape, as it were, the dangerous diet set before them. A little reflection upon the nature of the particular plant to which manure-water is to be applied will, in a great measure, be a safe guide as to the strength of the solution it is able to bear. As a rule, rampant-growing subjects will stand a much stronger mixture than weak growers—Rhubarb, for instance, being benefited by it at a strength that would injure Peas. Runner Beans may receive it stronger than the weaker-growing dwarf varieties; but, in all cases, it is better to be on the safe side, and rather make the solution too weak than too strong.

Flower Garden and Herbaceous Borders.—Attend to the requirements of the different plants in the flower garden by pegging them down and watering those that require it if the weather be dry, so that the whole may have a full finished appearance as soon as possible. If the soil appears to have been not rich enough for any particular plant assist it with manure-water. *Calceolarias*, above all things, must not be allowed to suffer for want of water, or the result will most likely be their dying off in quantity. Supply from the

reserve ground any blanks that may occur by odd plants going off. Spring bedding plants, recently removed to their summer quarters in the reserve ground, must not be allowed to want water, and should be still further assisted by keeping the ground clear from weeds. In herbaceous borders, when the tops of Crocuses and other spring bulbs have turned brown and are dying, they may be removed, but not before they have arrived at that state, or the roots will suffer; if these are grown in patches let a suitable stick be placed to each so as to denote where they are, without which all plants that die down are liable to be disturbed. Thin out late-sown annuals sufficiently to allow them the requisite room, and keep the ground perfectly clear from weeds, so that it may have an orderly neat appearance.

Dahlias and Hollyhocks.—As Dahlias advance in growth, see that they are kept regularly tied up. They should have three or four sticks to each plant, so as to keep them open and allow the sun and air to get to the centres. The practice of tying these plants up to a single stick is bad and unsightly; it causes them to run up tall, and affords little security against strong winds. To induce the plants to throw out strong side-shoots, pinch out the points of the leading growths. See that they are quite free from aphides, and, if any are detected, syringe with tobacco-water. Hollyhocks must be well secured to stout sticks as they increase in size, for if they get blown over it spoils them. They do not require the sticks so long as those sometimes used, unless grown in very exposed places, in which they should not be planted. If the sticks are 4 feet out of the ground after being firmly driven down, they are high enough. Do not tie them so tightly as not to allow sufficient room for the stems to thicken. On the other hand, they must not be left so loose as to chafe with the wind against the supports. Hollyhocks, as well as Dahlias, will be much benefited by a mulching of rotten dung a couple of inches thick.

Pits and Frames.—Cucumbers in frames should be gone over as often as is necessary, and the superfluous growth removed. It is a mistake to allow them to get too full of shoots as it exhausts the roots to no purpose; nor should they be allowed to carry too many fruits at one time. Cucumber plants, if kept clean, not over-borne—especially whilst young—and supplied with nutriment, will bear up to the end of the season. Continue to stop the shoots just above the joint where they show fruit, according to the advice given earlier, as this tends to prevent over-crowding, which occurs when they are allowed to run a joint or two beyond where the fruit shows. Any that have been bearing some time, and have filled the soil with their roots, should now receive manure-water twice a week, always giving this, as well as water used in a clear state, tepid. Melons that have set a crop of fruit should be well watered, and all useless shoots removed, and the whole energies of the plants will thus be directed into swelling off the fruit.

Houses—Stoves.—Gloxinias will now be full of flower, and will be assisted by an occasional application of manure-water. Keep them near the glass, so as to induce a stout, robust habit, without which the blooms are soft and useless. A shelf over the paths is a good situation for these plants. Achimenes in pots and baskets should have their stems supported with small sticks neatly tied thereto. It is not good practice to give all the plants an equal amount of shade. Allamandas, Bougainvilleas, Ixoras, and Dipladenias will succeed better with much more sun than many plants will bear, consequently they should be placed at the warmest end of the house, and only receive a slight protection from the sun in the middle of the day. Climbing plants that are grown in pots and upon trellises should, when they have set a good crop of flowers, be trained over the trellises, but not too closely. Subjects of the above character that are grown permanently as roof-climbers should not be allowed to go too long without training, or they become an impenetrable thicket of shoots, and necessitate much cutting away. Do not allow plants grown for this purpose to become too much crowded, or they suffer themselves, and injure everything grown under them.

Flower Garden and Pleasure Grounds.

All that is now required in this department will be unrelaxed attention to ordinary routine operations, and these, during very dry or unfavourable weather, will be sufficiently onerous, and must include careful treatment of the newly-planted flower beds, supplying them with abundance of water when the weather is dry; pegging-down, staking, and regulating the growth of the various plants; and making good any deficiency which may from time to time occur from the store of each kind of plant which has been used, and which should always be kept in hand for some time at least after the beds have been planted. Give plenty of water to fine-foliaged or sub-tropical plants in order to induce a free and vigorous growth, as only when in this condition can their great beauty be fully developed. Mulching the surface of the soil with partially rotted

manure, or some other porous enriching material is of the greatest importance, and tends to promote that equable state of moderate moisture which is of such consequence to all kinds of plants. In the absence, however, of any mulching material, keep the soil frequently stirred, so as to render the surface loose and friable, and thus prevent, to some extent, undue evaporation. Attend also to staking and tying-up Dahlias, Hollyhocks, and other tall-growing herbaceous plants, before they become bent or broken down; and, before doing this, the shoots may with advantage be carefully thinned out. Keep lawns, Grass walks, and belts, free from broad-leaved weeds of every kind, as their presence tends in all cases to mar the beauty of the turf. Now that the planting of the flower-beds and borders has been completed, it will be unlikely that heavy traffic will for some time take place upon the various gravel paths in and about the parterre; advantage, therefore, should be taken soon after the first considerable fall of rain, to loosen up the surfaces of all such walks, and apply a slight dressing of new and clean gravel. Rake the same level, and at once roll it well down with a heavy roller, and the walks will, in most cases, after this remain in good condition throughout the remainder of the season. Whenever the weather is dry, the barking of Oak should be pushed forward. By the end of the month, Coniferous seeds should be well above ground. Experience has proved that red lead applied to the seeds of Scotch Fir, Spruce, Larch, and similar seeds, just before sowing, is a sure preventive of ravages from birds. The young plants do not appear to suffer from the "coating," but whether or not the ground, if sown with red-leaded seeds for years successively, would be "sickened," is a question worth studying. Gather Elm seeds, and sow at once, before the coating of the seed hardens. Evergreen shrubs and trees, such as Portugal Laurels, Hollies, Cupressus Lawsoniana, &c., may still be planted, watering plentifully during dry weather.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Roses.

The climbing varieties of Teas and Noisettes need but little pruning if they are required to cover a house, or to furnish large quantities of cut flowers, as strong growth, and the laterals from this growth, are most productive of blooms. The lateral growths should, in my opinion, be pruned back to the stem as soon as the flowers are cut; fresh buds will then be sent out from the same stems, and Standen's, or any liquid manure, should then be applied to assist the plants in providing nourishment to the buds, which thus produce finer flowers. It is not to be supposed that these Noisettes or strong-growing varieties will remain well furnished if they are not thinned out at the proper time. If a plant is required to furnish a greenhouse or wall, the young shoots must be encouraged, and a few of the weaker shoots thinned out, and then by training the growth horizontally instead of perpendicularly, as in most cases is the practice, it will be found that the laterals will break more evenly, and the plants will not be so bare at the base. I have found that, by reversing the direction in which the strongshoots are growing before they break into flower, buds that have been quite dormant will be formed. If a plant of Maréchal Niel is required to cover a conservatory, it is advisable to carry one or two strong growths as high as the spring of the roof, and then direct the points horizontally, right and left. The shoots that spring from these may be carried, at equal distances apart, to the apex of the roof. If the shoots are carried at once perpendicularly, and without check, to the ridge of the house, they are sure to be very bare at the bottom, as the strong varieties of Teas and Noisettes do not break so freely as the Grape Vine does when treated on the same principle. If the above advice be carefully attended to, the plants thinned out, and the flower-shoots pruned back, it will be found, with watering and keeping the plants free from blight, that the Maréchal Niel, Devonensis, and Lamarque Roses will flower twice in the season.—H. G.

Indoor Fruit Department.

Vines.—Fruit on late kinds should now be set and ready for thinning. As late Grapes are ripe at a date when they are subjected to damp, the berries should be thinned out more than is necessary in the case of Grapes that are to be eaten as soon as ripe. No rule as regards distance between each berry can be laid down, as the same variety does not swell equally everywhere, but most people are more apt to err in thinning too little than too much. Black Alicantes must be thinned as soon as the berries can be seen, for, when left for a few days after this, the bunches generally become a solid mass, which cannot be conveniently operated upon. Lady Downes should not be thinned so early, as many of the berries are imperfectly set, which, if left to form a bunch, come to nothing. The berries of the black Lady Downes are also liable to become more deformed than any other kind; and, to obtain them of a perfect and uniform shape when matured, the worst-looking must be removed. Scalding of the berries during the stoning period is an evil which this variety is very

subject to, and, in those places where every means have failed to check it, the bunches should not be thinned so much at the present time as they will ultimately require, in order that there may be a reserve to take the place of those which may decay. Vines setting and swelling their fruit at an early stage should not be kept closer during the heat of the day than those colouring. They should, however, be shut up early in the afternoon, and a little air should be given in the evening and throughout the night. The atmosphere in houses where the fruit is ripe, or ripening, must not be kept too dry upon hot days, or the foliage, which is always of much service, even after the fruit is cut, will be injured. To prevent this, damp the pathways and surface of the border at mid-day, and in the afternoon when it seems necessary.

Pines.—When the successional plants in fruit are in a house or division by themselves, they are much benefited by being shut up as early in the afternoon as circumstances will permit until the fruit is out-of-bloom. The atmosphere should be made very moist by damping all bare surfaces; but avoid syringing the plants overhead while the fruit is in bloom, as this is a sure way of producing deformed fruit.—J. MUIR.

Hardy Fruit.

The sudden fluctuations in temperature of the last two or three weeks, accompanied with east and north-east winds, have caused blight to appear on all kinds of hardy fruits; Apples especially are attacked by it in a most virulent manner, and, if they are as bad in other districts as they are in this, I fear the crop will be light. The heavy rains of the last few days have been of great benefit to the trees, and let us hope that much of the fruit will thereby be saved. Thoroughly wash with the garden engine all infected wall trees; clear water, if used with force, is better than all the insecticides that have as yet been invented. Cut off the useless spray from Apples, Pears, and Plums, and any still requiring it should have the superabundant fruit removed forthwith. Morello Cherries should be treated in much the same way as Peaches, only, instead of disbudding, pinch all the shoots back to the first or second joints, with the exception of one at the base and top, and these should be laid in for fruit-bearing next season. Strawberries now ripe and ripening must be protected from birds by means of netting, from slugs by searching for them early in the morning and at night, and from rats and mice by trapping them. Layer runners both for planting out and forcing at the earliest opportunity in 60-sized pots, which are most convenient for the purpose; a piece of turf in lieu of crock will prevent the necessity for disturbing the roots when planting or potting. Our earliest kind this season was La Grosse Sucrée, which we gathered in quantity (from plants on a south border) on the 9th inst. The suckers on Raspberry "stools" should be well thinned out, leaving only four or five, and these the strongest on each stool; mulch with long litter, and water freely should dry weather again set in. Any kind of tree carrying a heavy crop of fruit may be effectually assisted by a mulching of manure, a watering with diluted sewage or liquid manure, or by an occasional sprinkling of guano or soot during showery weather; the manurial properties of the soot are much greater than many imagine. Like water, it is too cheap to be sufficiently valued.—W. WILDSMITH, *Heckfield*.

Winter Forcing Violets in America.—Cuttings are taken off during the winter and, when rooted, are potted-off into 2-inch pots and kept in a cool house until the spring. At the end of April a piece of new ground is secured, into which plenty of old manure is ploughed deep, and the soil thoroughly pulverised; in this the plants are placed 1 foot apart in the row, by 18 inches the other way. All runners must be taken off during the summer, and at the end of September the plants are lifted, potted into 7 or 8-inch pots, according to the size of the plants. They should be potted as firmly as possible, well watered, and the pots placed in an upright position out of doors. They should be removed to the greenhouse the first week in November, when fire heat should be sparingly used for some time, and the plants kept on the side benches, so as to be near the glass. The syringe must be used freely to keep off red spider, and the plants fumigated twice a week to save them from greenfly. If properly attended to, these Violets pay well, for they sell at 3s. per hundred during the holidays, and realise 2s. during the winter. The best crop I witnessed at any place was at Mr. John Henderson's, of Flushing, New York, last winter. They were a complete mass of buds, and I was assured they were the best plants they had for cut flowers. Most growers plant them out on the benches, but I do not think that this plan is as good as potting. Planting-out induces the plant to make more growth, though not a corresponding number of buds, while under the potting system the roots have not so much action, an unnecessary growth of wood is prevented, and the whole crown of the plant formed during the summer is forced into flower.

Marie Louise is the only kind now grown on a large scale for commercial purposes, as it produces a far larger number of buds than any other.—J. H.

Plants as a Test of Water.—The quality of water in relation to its fauna and flora has been the subject of investigation by some of the French Academicians. In substance the results seem to prove that water in which animals and plants of higher organisation will thrive is fit to drink; and, on the other hand, water in which only the infusoria and lower cryptogams will grow is unhealthy. If the water become stagnant and impure, aquatic plants of the higher order will languish and disappear, and the half-suffocated fish will rise near the surface and crowd together in parts where there may still be a little of the purer element trickling in, and if driven from these places they soon die. No mollusc will live in corrupt water. Plants also exercise a reactive influence on the quality of water. The most delicate appears to be the common Water-cress, the presence of which indicates excellent quality. Veronicas and the floating water-weeds flourish only in water of good quality. The Water-plantain, Mints, Loosestrife, Sedges, Rushes, Water-lilies, and many others, grow perfectly well in water of moderately good quality. Some of the Sedges and the Arrow-heads will thrive in water of very poor quality. The most hardy or least exacting in this respect is the common Reed, or *Phragmites communis*.—"Nature."

OUR WATER SUPPLIES.

WHILE our large towns are yearly becoming more and more alive to the necessity of improving their water supply, and rendering themselves independent of local sources that may suddenly fail when the demand upon them is most urgent, country districts have, in this respect, fallen very much behindhand. We hear of many villages, from which the supply of some neighbouring towns is mainly derived, left almost entirely without water themselves, or, at any rate, without facilities for obtaining in a regular manner their due share of it. The necessity in large towns, where local sources may be unequal to the demand upon them, or are liable to be contaminated by the noxious matter that may find their way into them, of devising an efficient artificial system of supplying the inhabitants with water, is so obvious and so pressing, that public attention would naturally be drawn to it first. But in rural districts, it is only occasionally, and not all the year round, that want of water makes itself urgently felt, and then the sufferers are for the most part poor people, who put up with the discomfort as one among the many inconveniences attaching to their position in life. Moreover, the deprivation being usually only of a temporary character, the hope that it may not last long, but that some seasonable changes of weather may bring relief, disposes them to endure it with little complaint, and, when the grateful change comes, to believe that perchance it may not occur again. Within the last year or two, the requirements of rural districts have, however, been brought into public notice, and facts have been elicited with reference to the distress which in periods of drought prevails in some of them, which are of a somewhat startling kind. We are accustomed to think that, in the country, at any rate, water is a commodity which, like the air we breathe, can be bought without money and without price. It is, therefore, a little astonishing to hear of some villages where, in dry seasons, the poor people have had to pay for it at the rate of a penny a gallon, and others where they bought it at twopence the bucketful, and were obliged to be so chary with it as to use the same water twice for washing, and to make one pailful serve the purpose of a household of six or seven persons. Yet the investigations instituted by certain members of the Social Science Association showed that these and similar results of deficient water supply have long existed in many parts of England. In several instances the discomfort occasioned to the poor from this cause has been due to the apathy or positive neglect of local landowners. It was only a few weeks ago that, on the estate of a wealthy but non-resident proprietor in one of the eastern counties, we ourselves came across a case of the kind, where the occupiers of a cottage of a somewhat superior class as a residence were driven to great straits for want of water. They had, said the wife—a remarkably decent woman, and the mother of half-a-dozen young children—nearly two buckets of rain water left; but they were almost afraid to make use of it, as they knew not where to get more when that was gone, while all the spring water they consumed was brought in bottles from a well, distant rather more than a mile from their cottage. This poor woman gave a practical illustration of the equanimity with which people in her station in life put up with discomforts that would be intolerable to those in a higher social position; for when we enquired how she could endure such a state of things, she answered cheerfully that they "lived in hopes of rain." Now this was a case in which, if the landlord had been resident, and

had managed his own property instead of leaving it to the care of an agent, the evil would probably have been soon remedied, as a proper tank for the storage of rain water might be constructed, if Sir Philip Rose's estimate of the cost of such receptacles be correct, for about five pounds. That a tank to hold the rainfall on the roof of an ordinary-sized cottage would generally suffice to supply the wants of the household for all purposes except for drink throughout the entire year, the enquiries of Mr. Bailey Denton and others who have paid attention to the subject have fully proved. That gentleman stated that a tank capable of holding 2,500 gallons, a quantity which may be collected from the roof of a cottage by conserving the rainfall to a depth of 6 inches—a depth less than half that which must be reckoned for under any circumstance—may be made for from six to seven pounds, and that this would afford a supply to a household of five persons, using four gallons each per diem, for more than a third of the year; and, of course, during many months it would be unnecessary to trench upon this store at all. Moreover, besides the consumption for various purposes by the population, the demands of live stock during a time of drought occasion, when the surface water is not caught and saved, great labour and expense in cartage, and often serious loss in the deterioration of the animals themselves, where the supply, however obtained, is deficient in quantity or bad in quality. At the discussion which followed the reading of Mr. Bailey Denton's paper, Mr. Baldwin Latham stated that the residents on the Surrey Hills were often dependent upon water ladled out of ponds, which was so thick that it had to stand for hours in buckets before it could be used; and the sight of cattle wandering over the meadows in search of the last drop of muddy water that may be left in the dried up ditches and pools is a pitiable one, which most of us have witnessed in a dry summer.—“Field.”

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

JUNE 16TH.

THIS was in all respects an attractive exhibition, the new plants staged by Messrs. Veitch, Bull, Williams, Rollisson, and Henderson occupying a prominent position in the centre of the tent. Stove and greenhouse plants, and Orchids, were well represented by Messrs. Williams and Jackson among nurserymen, and by Mr. J. Ward, and other amateur growers. Pelargoniums and Roses were also strikingly effective.

New Plants.—In Messrs. Veitch's collection of these, we remarked the following:—*Crinum americanum*, a fine kind, having bright green undulated foliage, and bearing a stout umbel of white-petaled pink-anthered flowers; *Zamia Wallisii*, a species with large oblong bright green leaflets or pinnæ, borne on the extremity of a long, slender, and gracefully arched petiole; *Dracæna Levangerii*, a native of the South Sea Islands, having deep green crimson-edged lower leaves, the young foliage being of a creamy-yellow colour, suffused with red; *Dracæna Tylori*, a robust and distinct garden hybrid, raised between *D. magnifica* and the well-known *D. Mooreana*, dense in habit and bronze-green in colour, the petioles being dark red as in *D. Mooreana*. *Sarracenia Stevensii*, a beautiful hybrid of free growth, having erect bright green pitchers veined distinctly with bright red; *Anthurium Scherzerianum longiflorum*, a distinct variety of the Flamingo plant, having very long and proportionately narrow spathes of a brilliant colour. The same group also contained a new species of *Verschaffeltia*, with vivid deep green leaves; the orange-yellow-flowered *Blandfordia nobilis*, *Cattleya Mendelii*, *C. gigas*, *Trichopilia lepida*, *Clematis excelsior*, a semi-double purple-flowered variety; *Croton Veitchii*; half-a-dozen well-grown Pitcher plants, in baskets, a fine specimen of the new epiphytal *Platynerium Willinkii*, and some pretty little plant curiosities in the form of *Darlingtonia*, *Cephalotus*, and *Droseras*. Not the least attractive plants in this group were some distinct and vigorous new seedling *Gloxinias*, among which were the following:—*G. Lisère d'Argent*, an erect-flowered variety, having scarlet-white-margined flowers flushed with pale rose at the back; *Boule de Neige*, an erect-flowered pure white variety; *Marquis of Lorne*, a large-leaved drooping-flowered variety of delicate lavender-purple with a pure white throat; and *Mrs. Haines*, a robust large-flowered sub-erect kind, of a deep rosy colour, with a crimson throat. Mr. Bull's collection was rendered conspicuous by a splendid specimen of *Godwinia gigas*, the mottled stem of which was as thick as one's wrist, and bore at its apex a great umbrella-like head of bright green leaflets. In the same group were also *Geonoma Seemannii*, a deep green-foliaged Palm, the ribbed leaves of which are bifid; *Pritchardia grandis*, a dense-habited Palm, having rounded fan-shaped foliage, of the brightest and deepest green imaginable; *Dipladenia Brearleyana*, with flowers of a bright crimson colour, the buds and partially-opened blossoms being delicately tinted with bright rose; *Bertolonia Van Houttei*, a kind having oblong leaves of a deep velvety green, netted and dotted with rosy-carmine; *Dracæna Goldiana*, a species with ovate acuminate deep green foliage, conspicuously barred with silvery-grey. Associated with these were also potfuls of the bright orange-yellow *Lilium Thunbergianum splendens*, the silvery-edged *Sibthorpea europæa variegata*, *Anthurium Scherzerianum album*, and

Hydrocotyle nitidula, a fresh green-leaved plant, closely resembling the Cornish Moneywort, and useful for the decoration of baskets; a potful of *Lilium canadense rubrum*, the flowers of which are more deeply coloured than those of the usual form; two plants of the singular looking epiphytal *Marcgravia paradoxa*, established on pieces of deal board, and afterwards severed from the parent stem. The same exhibitor had likewise effective groups of new *Dracænas*, among which were *D. Goldiana*, *amabilis*, *Guilfoylei*, *Hendersoni*, *metallica*, *Mooreana*, and others; also *Crotons volubile*, *spirale*, *undulatum*, *Youngii*, *Veitchii*, and *majesticum*. Mr. B. S. Williams had an effective group of new Palms, Ferns, *Dracænas*, *Crotons*, and *Orchids*; also well-flowered plants of the snowy-white *Lady's-slipper*, *Brearley's Dipladenia*, *Veitchia Canterburyana*, one of the most elegant of pinnate-leaved Palms of small growth; *Dracæna Fraseri*, and the singular-looking *Huntsman's Cup* (*Sarracenia purpurea*). Among new Ferns staged in this group, we noticed *Adiantum gracillimum*, the most delicate of all known Maiden-hair kinds; *Dictyogramma japonica variegata*, figured and described in our last issue; and *Pellaea ornithopus*, a delicately-cut tripinnate Fern, with glaucous-oblong pinnæ set on a slender black rachis. Messrs. E. G. Henderson & Sons contributed an effective group of new florists' flowers, succulent plants, Ferns, and stove and greenhouse plants, among which were *Pilocereus senilis*, commonly called the “Old Man Cactus,” owing to its apex being covered with long white hairs; *Eryngium eburneum*, with Aloe-like bright green spinose leaves, and a variety of *Sedum californicum*, glaucous and rosette-like in habit, and bearing clusters of bright yellow flowers. In the same collection were several new variegated *Dioscoreas*; a plant of the curious deciduous terrestrial Orchid, *Pogonia discolor*, *Kämpferia Roscoeana*; *Eranthemum reticulatum aureum*; *Lomatia elegantissima*, a distinct greenhouse shrub, having finely-divided bright green leaves, useful for button-hole bouquets; *Podocarpus macrophylla variegata*, a distinct Japanese shrub, having bright green leaves, margined with white; *Sonchus elegantissimus*, one of the most elegant of all dinner-table plants; some new hybrid succulents, including *Echeveria spathulata*, *grandisepala*, *imbricata*, and others; also the new *Echeveria Peacocki* (*E. Desmetiana*), *farinosa*, a beautiful silvery form, and the deep bluish-green *E. eximia*. This collection was set off to advantage in front by means of small specimens of *Adiantum Farleyense*, the young fronds of which had acquired a deep rosy tint, owing to their having been grown in an airy house without shading. Some neat little specimens of *Thalictrum minus adiantifolium* were also much admired; for Fern in bouquets and other floral decorations this forms one of the best of all substitutes.

Stove and Greenhouse Plants.—These were well represented by Mr. Ward, Mr. Wheeler, Mr. Donald, Mr. Ritchie, Mr. Mearns, and others among amateur growers; and by Mr. B. S. Williams, Messrs. Jackson, and Mr. Morse among nurserymen. Mr. Mearns had an effective and well-grown group in which were *Stephanotis floribunda*, 4 feet in height, a perfect mass of snowy blossoms; well-grown *Bougainvillea glabra*, profusely covered with mauve-coloured bracts; the scarlet-spathed *Anthurium*; *Dracophyllum gracile*; *Erica Cavendishi*; and others. Mr. Ward furnished well-staged plants of the purplish-blue *Statice profusa*; *Erica tricolor impressa*, 4 feet in diameter; a well-bloomed specimen of *Kalosanthes coccinea* var. *Phoenix*, one of the most showy of its class; *Bougainvillea glabra*; *Clerodendron Balfourii*; *Aphelexis macrantha*; and others equally well grown. In the class of six plants, Mr. Ward was also first with the vivid orange-flowered *Ixora Williamsii*, *Aphelexis macrantha purpurea*, the delicate rosy-tinted *Erica Candolleana*, *E. Cavendishi*, and good specimens of *Stephanotis floribunda* and *Statice profusa*. Messrs. Jackson staged twelve small but well-grown specimens, consisting of the white *Ixora Colei*, *Allamanda cathartica*, *Statice profusa*, two or three *Azaleas*, and a vigorous specimen of *Phænocoma prolifera*. Mr. Williams furnished an effective group of six well-bloomed plants, including the scarlet-spathed *Anthurium*, bearing from twenty to thirty brilliant bracts; the pale yellow *Allamanda grandiflora*, *Dracophyllum gracile*, *Aphelexis macrantha purpurea*, and *Hederoma tulipiferum*, in beautiful condition. Heaths, both well grown and flowered, were staged by Mr. Ward and Messrs. Jackson, and a splendid bank of fancy and show Pelargoniums came from Mr. Ward, Mr. James, Mr. Turner, Mr. King, Mr. Catlin, Messrs. Dobson, and others. Mr. Burley contributed several baskets of new silvery-variegated and scarlet-flowered zonal Pelargonium, and a *Coleus* similar in colour and habit to *Duchess of Edinburgh*. Mr. Bull exhibited his new Pelargonium *Queen Victoria*, and a new semi-double-flowered Ivy-leaved variety named *P. longipes König Albert*, a free-growing plant with rosy-lilac flowers.

Orchids.—Of these a fine group came from Mr. Denning, gardener to Lord Londesborough, who had splendid plants of *Lælia purpurata*, with three spikes, embracing in all seventeen flowers; *Dendrobium formosum*, with fourteen fully opened flowers of pearly whiteness, each having a great orange-yellow blotch on its widely expanded lips; *Dendrobium Bensoniæ*, with nine flowering bulbs; *Anguloa Clowesi*, with fourteen or more great yellow Tulip-like blossoms; a vigorous plant of the well-known *Oncidium Lanceanum*, bearing a great branched spike, on which there were twenty-five flowers; and the robust-growing *Aërides Lindleyanum*, 5 feet high, with two branched spikes of white rosy-lipped flowers. Mr. J. Ward contributed a well-grown collection, in which were *Masdevallia Harryana*, with fifteen blood-coloured flowers; a superb example of the Shaggy *Lady's-slipper* (*Cypripedium villosum*); a strong specimen of *Odontoglossum crispum*, bearing seven or eight fine spikes; and a beautiful example of *Phalænopsis grandiflora*, bearing seven well-bloomed spikes of snowy blossoms. Mr. Ward, Mr. G. Wheeler, and Mr. Heims also all showed groups of twelve plants; in Mr. Ward's collection was a well-flowered plant of the Ceylon Mayflower

(*Dendrobium M'Carthyi*), bearing about thirty fully expanded blossoms; also a vigorous plant of *Epidendrum vitellinum majus*, bearing two stout spikes of large scarlet yellow-lipped flowers. Mr. Heims furnished a plant of the Mexican Mayflower (*Lælia majalis*), the variety of *Phalænopsis grandiflora* called *aurea* or *Ruckerii*, and a well-bloomed specimen of *Aërides odoratum majus*, bearing at least twenty spikes of fragrant wax-like blossoms. In the nurserymen's classes, Mr. B. S. Williams, Messrs. Jackson, and Mr. Morse, were the principal exhibitors. In the class of six Orchids, Mr. Williams had well-furnished plants of *Cattleya Mossiæ*, *Odontoglossum Pescatorei*, the Bearded Lady's-slipper—with about fifty well-developed flowers, *Anguloa Clowesi*, a good *Sobralia macrantha splendens*, and a noble plant of *Aërides odoratum majus*, 5 feet high, and well bloomed. In the class of twelve plants, the same exhibitor staged *Masdevallia Harryana*, bearing twelve flowers; *Cypripedium spectabile*, bearing ten fully-open flowers; the *Madeira Orchis foliosa*, with eighteen densely-packed spikes of purplish-lilac flowers; *Anguloa Clowesi*, well-bloomed and excellent examples of *Cattleya Mossiæ*, *Vanda tricolor*, and *Cypripedium superbum*. Messrs. Jackson staged smaller but equally well grown specimens, the more remarkable among which were *Cattleya Mossiæ superba*, with large and beautiful blossoms; and fresh specimens of *Aërides crispum*, *Cattleya Mendeli*, *Epidendrum crassifolium*, and *Dendrobium Parishii*.

Roses and Ferns.—Messrs. Paul & Sons, Cheshunt, staged collections of Roses, among which were fine examples of *Celine Forestier*, *Camille Bernardin*, *Jules Chrétien* (a delicate rosy-lilac variety of good form), *Madame Victor Verdier*, and the soft rosy *Madame Laurent*. Messrs. Paul also furnished a splendid miscellaneous collection of small, but remarkably well-bloomed, pot Roses, among which we noted *La France*, one of the best of light show varieties; *Madame Rivers*, an old-favourite, having delicate pink globular flowers; *H. P. Duke of Edinburgh*, a glowing crimson-scarlet; *Princess Beatrice*, a soft blush; and many others. Messrs. Veitch & Sons contributed a well-arranged group of pot Roses, backed up by elegant cut-leaved Japanese *Acers*, and set off in front by boxes of cut Roses and shrubby *Peonies*. A new hybrid *Perpetual Rose*, named *Sultan of Zanzibar*, was exhibited by Messrs. Paul & Sons. It is glowing crimson-scarlet in colour, and a seedling from *Duke of Edinburgh*, bright and distinct, and is sure to become a favourite. Mr. Chas. Turner, of Slough, sent ten stands of cut Roses in admirable condition, some of the flowers being very fine and beautifully-coloured. As regards Ferns, six good specimens were staged by Mr. Donald, gardener to J. Barclay, Esq., Leyton. Among these were well-grown examples of *Gleichenia dichotoma*, *Adiantum Cardiochloa*, *Dicksonia antarctica*, *Cyathea dealbata*, and others. Mr. Shear, gardener to E. Brooks, Esq., Highgate, had a splendidly-grown *Adiantum Farleyense*, a good *A. cuneatum*, and a fine mass of the pale green *Leucostegia immersa*. Mr. Child, gardener to Mrs. Torr Ewell, staged a fine mass of *Davallia bullata*, fresh and effective; *Adiantum Farleyense*, in fine trim; and a noble *Gleichenia Speluncæ*. Mr. B. S. Williams had splendidly-grown examples of *Gleichenia Mendeli*, and *G. Speluncæ*; also a noble specimen of *G. semivestita*. Mr. Ritchie furnished an excellent group, including one of the finest specimens of *Davallia Mooreana* we have yet seen; and the same may be said of a specimen of *Gleichenia dicarpa*, staged in a group of fine-foliage plants by Mr. Child.

Miscellaneous Subjects.—A group of cut specimens of hardy flowering shrubs came from Messrs. Veitch, including the yellow-flowered *Fremontia californica*, *Escallonia macrantha*, *E. sanguinea*, several kinds of *Andromeda* and *Spiræa sorbifolia*. The same exhibitors also had a new weeping purple-leaved *Beech*, and a basket of *Cissus orientalis*, an extremely elegant cut-leaved climber. Mr. R. Parker, of Tooting, staged an effective group of hardy herbaceous plants, among which we noticed good specimens of *Orchis foliosa*, a purple-flowered species from *Madeira*; *Spiræa palmata*, with bright rosy flowers; two good potfuls of the orange-flowered *Lilium Thunbergianum*; rose and cream-coloured *Peonies*; and some effective varieties of *Pyrethrum roseum*, together with *Spiræa Aruncus*, *Erigeron purpureum*, and others. The same exhibitor also staged some effective stands of cut flowers of *Peonies* and rosy *Pyrethrums*. A group of herbaceous plants came also from Mr. G. Wheeler. Mr. Ley, of Croydon, contributed an effective collection of *Palms*, *Cycads*, and other decorative plants, among which were new *Marantas*, *Abutilons*, and other plants. Some dwarf free-flowering blue and purple bedding *Violas* came from Mr. Gray, Eglinton Castle, Irvine, N.B. Mr. Laing, Stanstead Park, sent an effective group of bronze zonal *Pelargoniums*, *Ferns*, *Palms*, *Pandanus*, and other decorative plants. Messrs. Rolisson & Sons showed a fine panful of *Dionæa muscipula* or *Venus's Fly-trap*, and some well-grown plants of the beautiful new *Bertolonia Van Houttei*. The exhibition was visited in the morning by the Seyyid of Zanzibar, who seemed to take much interest in it. He has himself been the means of introducing many new plants into Zanzibar, upon the improvement of the gardens of which he is said to bestow much attention.

Plants to which Certificates were Awarded.—*Asplenium ferulaceum*, *Alsophila hirta*, *Anthurium cordifolium*, *Davallia Youngii*, *Dracæna Taylori*, *Nepenthes rubra*, *Platynerium Willinkii*, *Zamia Wallisii*, *Begonia Emperor*, *Betula purpurea*, *Purple-leaved Peach*, and *Gloxinias Madame Patti*, *Marquis of Lorne*, and *Lisère d'Argent*, from Messrs. Veitch; *Kentia Moorei* (true), *Sibthorpia europæa variegata*, *Croton picturatum*, *Dracænas Rex*, *triumphans*, and *rubella*, *Lomaria Dobroydensis* and *capensis*, and *Cybotium Menziesii*, from Mr. Bull; *Sedum californicum*, *Saxifraga notata*, *Zamia colocoma*, and *Dracæna Princess of Wales*, from Messrs. E. G. Henderson; *Pellæa ornithopus* and *Zamia Lindenii* from Mr. B. S. Williams.

ROYAL HORTICULTURAL SOCIETY.

JUNE 16TH.

MESSRS. Veitch furnished on this occasion half-a-dozen new plants; and a collection of new double white and scarlet-flowered Zonal *Pelargoniums* came from Mr. Laxton, of Stamford. The Rev. M. J. Berkeley made some remarks on a supposed new form of Potato disease alluded to elsewhere (see p. 500).

[Floral Committee.]—Messrs. Veitch & Sons staged the following new and rare plants:—viz., *Dracæna Taylori*, a robust growing kind, with broad oblong, wax-like foliage, of a dull bronze-green tint, the petioles being of a deep red tint; *D. elegantissima*, one of the small-growing section, having slender lance-shaped bronze-tinted leaves, margined with bright crimson; and *Asplenium ferulaceum*, an elegant Fern from Colombia, having finely divided bright green fronds, which arch gracefully over the sides of the pot. Mr. Laxton, of Stamford, sent some seedling white and scarlet double-flowered zonal *Pelargoniums*, among which *Pearl*, the *Ghost*, and *Boweanum*, were conspicuous. The best, however, was *Wilfred*, alluded to below. *Fair Maid of Kent* is a strong-growing, free-blooming double blush kind. *Tom Tit*, scarlet, and *Guiding Star*, are also both effective rose or magenta-coloured sorts. The same exhibitor likewise sent two new seedling *Roses*, viz., *Vivid* (H. P., a bright crimson-scarlet), and *Lady Isabel Cecil* (a creamy-yellow tea-scented variety, likely to be a valuable addition to its class). Mr. F. Perkins, of Leamington, furnished a semi-double flowered form of *Lilium Thunbergianum*, a golden-leaved form of the common *Hart's-tongue Fern*, and a strong plant of *Pteris serrulata major cristata*. Messrs. J. Carter & Co. staged strong plants of a new *Coleus*, having large maroon foliage, edged with yellow, but no great advance on *C. Bausei*. Cut blooms of Bedding *Pansies* came from Dr. Stuart, Hillside, Chirnside, N.B. Messrs. Cripps & Sons, Tonbridge Wells, contributed plants of their new *Clematis leviathan*, a large double form, not equal, however, to *C. Fortunei*; *C. Grande Duchesse*, is a strong-growing variety, to which allusion is made below. The same firm also staged a boxful of cut blooms of *C. Excelsior*, a fine semi-double variety, of a deep purple colour, each segment being terminated by a slender white awn-like point. Mr. J. Wilshire, Beaconsfield, Bucks, contributed cut flowers of a new seedling *Perpetual Picotee*, named *Minnie*, the flowers of which are whitish, flaked with reddish-purple, and of good form. Mr. R. Dean sent a basketful of a new blackish-purple bedding *Pansy*, named *Othello*, which promises to be useful and distinct. It has been forwarded to Chiswick for trial. Mr. Dean also sent a flowering specimen of the pretty little *Primula scotica*, having farinose leaves, and a truss of bright carmine flowers with a yellow eye. It is a little gem in its way, and succeeds perfectly in a moist, shady frame. Associated with this was a group of very beautiful single and semi-double-flowered plants of *Campanula Medium*, or *Canterbury Bell*, the flowers of which were large, and of every shade of white, rose, and purple. Mr. Dean also had a large-flowered variety of *Lobelia compacta*, named *Joli cœur*, the colour being porcelain-blue, splashed with white. Mr. C. Ross, gardener to C. Eyrie, Esq., Welford Park, Newberry, sent a cut spike and foliage of the fragrant rosy-purple-flowered *Crinum amabile*, and some well-grown little plants of *Scutellaria Mocciniana*, bearing terminal clusters of bright orange scarlet flowers came from the Society's Garden at Chiswick. These plants were grown from spring-struck cuttings, and others rooted now will flower next winter. It is a bright and easily-grown plant if pinched so as to render it bushy. Mr. McIntyre showed examples of mud flower-pots, which are found to be very useful for bedding plants, inasmuch as they saved labour in spring. They were described and figured in THE GARDEN, Vol. I., p. 27. Mr. J. Bateman sent a sample of *Paraguay Tea*, the produce of *Ilex paraguayensis*, a South American form of *Holly*.

Fruit Committee.—Mr. Laxton contributed a dish of a new *Pea* named *Dr. Hogg*, said to have been plucked from a row sown on March 18th, and a fine dish of a new *Strawberry* named *Pioneer*.

First-class Certificates were awarded to the following new plants:

Clematis Grand Duchess (Cripps).—A strong-growing, large-flowered, and very effective eight-sepaled variety, the flowers of which, in some instances, were as much as 10 inches in diameter, but often only 8 inches. The colour is white slightly flushed with rose.

Begonia Emperor (Veitch).—A very robust and distinct variety, belonging to the tuberous-rooted section, having bright green leaves tinged with brownish markings and axillary clusters of large flowers of a remarkably brilliant colour. As a half-hardy decorative plant it will prove of the highest value.

Double-flowered zonal Pelargonium Wilfred (Laxton).—A free-growing dark-zoned variety, of moderate growth, bearing compact trusses of rosette-like flowers, white in colour slightly tinged with blush. It is a decided improvement on any other double white-flowered form both in habit and flower.

The following new bedding *Pansies* have received First-class Certificates at Chiswick, where they have been grown on trial during the present season, viz.:

Pansy Bedfont Yellow, *White Swan*, *Lothair*, and *Magpie*, all from Mr. Dean; *Queen of Lilacs*, *Alpha*, and *Snowflake*, from Messrs. Dickson; *Blue Perfection*, from Mr. Westland; *Dr. Stuart*, from Mr. Stuart; and *Novelty*, from Mr. Cocker.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

PLANTING OUT v. POT-CULTURE.

Most observers of indoor gardening must have seen evidence in favour of planting out, as compared with pot-culture. The tendency of our flower shows and indoor cultivation for many years past has been wholly in favour of pot-culture. At one time plants were rarely seen in good condition otherwise than in pots. Occasionally, here and there in England, one saw a superb collection of Camellias planted out, as at Bicton, Chiswick House, or the Exeter Nurseries; but, as a rule, it was pot-culture everywhere. The system answered well enough where means were abundant, and skilful cultivators were at hand. Under less favourable circumstances, the aspect of plant-houses was frequently of anything but an attractive character; and, as for the conservatory, an equal space in the nearest flowery lane in summer was a paradise in comparison. It was in conservatories and winter gardens, arranged in a picturesque manner, that we became convinced of the great advantage of planting out Palms, tree Ferns, and many other plants. The gain was great, from an effective point of view, and the saving to the cultivator in tubbing, watering, &c., was very great also. We, however, were not aware that the system was equally applicable to numbers of small plants till we saw the glass-gardens devoted to the growth of flowers for cutting in America. There the English visitor is surprised to see large houses filled from end to end with tree Carnations, Roses, Poinsettias, Bouvardias, and many other plants, which we never think of planting out in a greenhouse. It need hardly be added that the houses are, in nearly all cases, specially adapted for their occupants, for it appears that to make use of houses in this way is next to impossible in a private place, where but few of each kind may be required; nevertheless, the facts are worth bearing in mind. It may be noticed that in Mr. J. Howatt's articles on cut flower culture in the United States, written after much experience there, planting out is practised in connection with the various plants he has written on. Our note on Mr. Ladds' grove of Gardenias, planted out at Bexley Heath, will probably be remembered by some of our readers as bearing on this point. We are glad to see that the subject is beginning to engage the attention of cultivators in this country, and a very sensible article on the subject in the "Gardener" deserves a place in our columns. The writer says:—"Any means whereby a saving of labour can be effected without in any degree impairing results, is worthy the attention of gardeners in these high-pressure times, when so much is expected to be accomplished without provision for extra help. But when the results obtained, when working on this principle, are not only as good as in cases where a greater amount of labour would be necessary, but even better in all respects, then it is to the advantage, even of those who have labour sufficient for all purposes, to follow the same system. We were induced to turn many winter and spring-flowering plants out of their pots, and plant them in the kitchen-garden quarters; and, in many instances, the plants were much stronger grown than if grown on in pots. That very useful plant, *Calla æthiopica*, divided in June, and planted with some fresh soil in which to root, made splendid plants. *Spiræa japonica* does well divided. *Deutzia gracilis* and *D. crenata* fl. pl. make very strong growth planted out and treated liberally. *Brugmansia* Knighti, turned out in June, and kept drenched with water during dry weather, makes rapid progress. *Solanum pseudo-capsicum* should have the benefit of five months in the kitchen-garden—no fear of stunted plants and yellow foliage when grown thus; Violets for winter-blooming in pots may be planted early in May in a prepared bed, and lifted and potted in autumn. *Primula Sieboldi*, the early-flowering *P. denticulata*, and *P. purpurea*, may be left out until they are required for the conservatory. The double varieties of the common Primulas, and any other of the stronger-growing sorts, do well planted out and lifted in early

winter. Acacias, Cyclamens, *Prunus sinensis* fl. pl., Lilacs, and *Weigela rosea*, may all be planted out. *Dielytra spectabilis*, *Schizostylis coccinea*, or other hardy flowers used, do better planted out than kept in pots. As a means of obtaining large specimen plants of Pelargoniums of the zonal section, it merely requires the plants to be pot-bound before planting. These should have the roots cut with a spade, a portion a fortnight, and the remainder about a week, before lifting the plants. We intend planting a few of the best Cinerarias out this summer, for the purpose of getting large plants for early flowering and cutting; also some yearling Chinese Primroses, potting these latter especially into small pots. Where pits are used for raising seedlings, growing Potatoes, &c., such things as *Rivina humilis*, *Libonia floribunda*, *Eranthemum pulchellum*, winter-flowering Begonias, &c., may be planted out with advantage. As an instance of what may be done with French Beans, in the second week of February we had some sown in a sunk stove pit, and have been able to supply a dish almost daily from the third week in April; with ordinary care we expect to have a supply from these till the outdoor crops are ready for gathering. The space these Beans occupy is 24 feet by 2 feet; they have been surface-dressed once, and the total depth of soil in which they are growing is less than 5 inches. They have never been syringed, but have been freely aired, and are so far entirely exempt from the attacks of insects. If these had been grown in pots we could have looked for no better results, whilst the amount of labour required would have been much greater. The vast superiority shown by Camellias planted out over those grown in pots or tubs is pretty well known—a superiority which is not confined to the Camellia alone, but which is common to all shrubby, stove, and greenhouse plants we have seen tried. We know that the beautiful Bougainvilleas only thrive well when planted out. For climbers of all descriptions, if any returns commensurate with the trouble involved are expected, planting out into borders of more or less extent must be the means employed. We particularly mean such as *Stephanotis floribunda*, *Hoya carnosa*, *Dipladenias*, *Allamandas*, *Lapagerias*, *Plumbago capensis*, *Clerodendron Balfouri*, &c. What fertile flower-producers Zonal Pelargoniums, Fuchsias, Heliotropes, and other common flowers become when allowed space at root and room to develop at top, in any sort of intermediate house! What a wonderful display of beautiful buds the Maréchal Niel Rose gives when planted out and allowed its own will to ramble about overhead in the conservatory. The golden buds seem to turn their faces down for the enjoyment of those below. That excellent button-hole Rose, Madame Falcot, should have a part of the border for itself, and be grown as a pillar-Rose—in a mild temperature, a supply of buds will be produced throughout the winter and spring, summer and autumn. THE GARDEN has been calling the attention of its readers to the great success that Mr. Ladds, of Bexley Heath, attains with Gardenias planted out. These are free-flowering and easily grown under pot-treatment; but it seems, when planted out, there is no comparison between the two systems of growth.—R. P. B."

Beschorneria yuccoides.—This singular-looking plant is now in flower in the American garden here. It has been growing on a bank amongst Yuccas for the last seven years, and this is the second year in which it has flowered. It was introduced from Mexico when I was in the gardens at Chiswick, about twenty years ago, and belongs to the order Amaryllidaceæ, being nearly intermediate between Agaves and Yuccas. The stem, or flower-spike, is 6 feet in length, and has sixteen side branches. It branches out immediately from the base, and each branch lengthens as it approaches the top of the spike. It is peculiarly striking before the flowers open; more so than afterwards, as the brilliant crimson colour of the bracts and flower-stems gradually fades as the flower advances in growth. Generally speaking, the plant resembles a Yucca in habit, and is equally hardy here; but, of course, we do not experience the severe frosts of the northern parts of England, being close to the sea, and our winters are warmer, and the summers cooler, than even in the neighbourhood of London. Here it forms a most effective object out of doors; but the plant well deserves a place in every conservatory or winter garden.—HENRY MUNRO, *Cleavelands, Lyme Regis*. [This beautiful plant, of which we have received excellent specimens from Mr. Munro, closely resembles the *B. Tonelii*; but the last-named species has not the large brilliant crimson-coloured bracts which belong *B. yuccoides*.]

NOTES OF THE WEEK.

— PROFESSOR RILEY, the state entomologist of Missouri, who is now in London, informs us that it is a mistake to suppose that the Potato beetle is not to be feared in European countries because of the climate. From what he knows of the insect, he considers the climate of Britain even better suited for it than that of eastern America; precautions against its introduction cannot, therefore, be too stringent.

— FOXGLOVES make some parts of Kensington Gardens just now as beautiful as many spots where Nature is the gardener. We wish Mr. Gibson and his foreman, Mr. Cole, every success in thus trying to embellish with beautiful hardy flowers the dismal areas of earth which, in summer and winter, have hitherto been a main feature in our parks. There is no surer sign of intelligent gardening than having all the ground inhabited, so to say, by plants. We have no doubt the day will come when large areas of bare dug surface will not be tolerated in spring or summer; and, it cannot be too generally known, that they are as unnecessary as they are offensive.

— THE anniversary festival of the Gardeners' Royal Benevolent Institution is to take place on Friday next, the 2nd of July, when contributions in the shape of fruits and flowers, to assist in decorating the tables and rooms, will, we are informed, be duly appreciated.

— AN importation of Indian Dendrobies has recently been received by Messrs. Low, among which the beautiful *D. Wardianum* is well represented, as are also *D. Bensoniæ*, one of the prettiest plants in the genus; *D. transparens*, and the Trumpet Dendrobe (*D. lituiflorum*), all of which have been received in excellent condition.

— A PLANT of *Cypripedium superbiens*, in Mr. John Day's collection at Tottenham, is just now bearing thirty-two flowers, and is at once a most striking and effective object. Several plants of the new *Odontoglossum vexillarium* are also in flower in the same collection, as are also plants of *O. Roezlii* and *O. Warszewiczii*.

— MR. FALCONER, writing to us from Brenham, Texas, says:—Our fruit season has now begun in earnest. Chickasaw Plum trees are loaded with ripe and ripening fruit, which, although not very fit for dessert, is excellent for cooking, and coming into market so early (15th May) is very profitable. This variety grows in the poorest soil, makes fine, solitary, broad-headed trees, or forms a dense thicket or wind screen, and may be easily reproduced from suckers, which bear fruit when very young. This Plum tree stands a frost of 25° with impunity, and is so tenacious of life that I do not think cultivators pay enough attention to it.

— THE so-called tobacco-meal, says the "Kölnische Zeitung," has been successfully used for the destruction of noxious insects, but it has not yet been applied largely on account of its high price, which is caused by heavy import duty. The Prussian Minister for Agriculture has just addressed a letter to the Minister for Commerce with a view to reduce this duty, or to take it off entirely. A Hamburg firm is said to have a stock of over thirty tons of this meal.

— WE have received, from Mr. Ware, a beautiful bloom of the Showy Lady's-slipper (*Cypripedium spectabile*), which is now flowering freely in moist shady spots in his nursery at Tottenham; also a fine spike of the rosy-purple-flowered *Orchis foliosa*, being part of a tuft of thirty or forty such spikes, which are now in beautiful condition in the same establishment. Along with these, likewise, came a handsome variety of *Calochortus venustus*, and the lovely crimson-flowered single Rose, called *Rosa rugosa*, a vigorous-growing, spiny kind, furnished abundantly with foliage of the richest possible shade of green. This, and the single white Rose mentioned by us a short time ago, would contrast charmingly one with the other.

— THE Texan Peach crop is said to be unusually heavy this year, but owing to the backwardness of the spring it is nearly a fortnight later in ripening than usual. Rivers's Peaches succeed extremely well in Texas, and now (June 6th) cultivators are picking most beautiful samples of Early Beatrice, Early Louise, and Early Rivers, and that, too, before they have got a single fruit from Hale's Early, Plowden's Early, or Troth's Early. Rivers's Early Victoria ranked amongst their finest Peaches last year.

— THE following Orchids, amongst others, are now in bloom in Mr. Bockett's collection at Stamford Hill, viz.:—*Cypripedium Stonei*, with five spikes bearing in all eighteen flowers; *Masdevallia trochilus*; *Saccolabium præmorsum*, bearing three fine wreath-like spikes; *Aërides affine superbum*, with eleven spikes; *Eriopsis rutidobulbon*, one of the most distinct and effective of all Orchids, its purplish pseudo bulbs having the texture of shagreen leather, while the flowers are yellow shaded with brown, the apex of the lip being white and the column of a bright emerald green tint. Associated with these was the strong-growing *Epidendrum leucochilum*, which has just flowered, the blossoms being greenish-white, and the massive three-lobed lip of ivory-like whiteness. It is one of the largest and most distinct of all *Epidendrums*, and one which is deliciously fragrant.

THE FRUIT GARDEN.

AIR ROOTS ON VINES.

WHAT are known as air roots on Vines are the root-like growths which push from the wood above ground. They generally appear in the greatest quantity near the spurs, and less frequently upon the clean wood or stem. They usually number from two to a dozen, or even more—sometimes coming in bunches, and sometimes in rows. They resemble earth roots in some respects, but they do not often divide into rootlets; they begin to grow with the rise of the sap, and continue growing until it descends again. All varieties of Vines are subject to them, and it is often said they do no harm, which may, perhaps, be correct, so long as they are few and small, but there is reason to believe that, where they occur to any great extent, they at all events do no good. I was lately requested by an amateur to come and see his Vines, as he could not understand why he had no Grapes on them this season. I ascertained that for some years air roots had been annually increasing and the crops diminishing. This year they hang down over a foot in length, and there is not a vestige of fruit on one of the Vines. There can be little doubt that these air roots have, in a great measure, brought this about, and, if their influence in this case has been antagonistic to fertility, it may be assumed that they will always produce effects which will be more or less injurious in proportion to the frequency of their occurrence, for the nourishment which supports these roots, or other superfluous growths, is that which should properly go towards the formation of fruit-bearing wood. Air roots should, therefore, be regarded and treated as any other Vine disease. They are the production of an imperfect root action in the first place, and a damp atmosphere encourages their growth afterwards. Young Vines are not so liable to become affected as those that are middle-aged or old. Vines, on which the berries shank, generally form air roots, but they also occur on those that are quite free from this disease. Their growth is often very vigorous when the Vines are first started, especially if they are kept close; afterwards, when more air is admitted, their points get starved, and further growth ceases; where this is the case, they do not do so much harm as when they continue growing throughout the season; and this they always do if not checked in time. Cutting, or rubbing them off, when they are growing vigorously, does no good. The points do not start into growth when once broken; but a second batch is invariably pushed from the base of the first. It is as well to let those that do appear remain and grow until the end of the season, when they may be cut away with a sharp knife while pruning. Vines, with their roots in borders which are damp, or in which all the fibre of the soil has decayed, generally produce plenty of air roots, as a close adhesive soil is not conducive to the healthy development of any Vine. When air roots appear in quantity, no time should be allowed to pass without making an examination of the border. Fresh drainage, where necessary, must be resorted to; and a quantity of fibrous turf and lime rubbish is of service in sweetening the soil. After the border has been thus renewed, the atmosphere of the Vinery should be kept dry during the early growth of the Vines. J. MUIR.

Vine-rod Excrescences.—Last year you expressed a wish that I should send you some examples of these, should they reappear this season. I therefore send you one cut from where there used to be an old spur. Last year it grew upon the underside of the rod, and attained the size of a goose's egg, and when pruning the Vine I pared it completely off—in fact, I pared until I laid the wood all bare. I found six maggots in it, and probably there were more, as I cut it away in large pieces, and did not examine it very minutely. The Vine on which the excrescence appears is West's St. Peter's; it is bearing a capital crop of Grapes, and is evidently in perfect health.—DOUGLAS BROWN, Mocollop Castle Gardens, Ireland. [In our former reply to our correspondent we remarked that we were not aware of any gall of the kind he mentioned, and we assumed that it might be a gall from his mention of grubs inside it. The example he has now sent shows that it is not a gall, but merely the not uncommon excrescence arising from hypertrophy. The grubs of which he speaks can have nothing to do with its production. They will probably be the maggots of flies which have deposited their eggs in the soft excrescence. There were none in the specimen sent.—A. M.]

THE INDOOR GARDEN.

CULTURE OF DIPLADENIAS.

ALL who have a stove, however small, should endeavour to grow a Dipladenia, which need not occupy much room; when in bloom, no stove plant with which I am acquainted is more beautiful or showy. Those, indeed, who have the room, should not confine themselves to one variety, but should have three or four. In the first place, I would advise those about to grow Dipladenias to secure strong, clean, healthy, and young plants from some nursery; and, if obtained in autumn, they can be properly prepared for being started into growth, the time for doing which will depend on the time when they are wanted to flower. They will, however, require a little rest before they are started into growth, when water should be altogether or nearly withheld. If they are in small pots, give them a shift, slightly reducing the ball, and spreading out the roots, but taking care not to injure any of them. If started in November, they may be expected to bloom in June; but plants not required till the end of that month, or till July, need not be started before Christmas, and plants not started till then, and

subsequently, will, if managed properly, remain in bloom till September.

When placed in the stove, plunge the pot half-way in some plunging material, such as cocoanut fibre. About the middle of February or beginning of March, give the plant or plants, as the case may be, a final shift into 12 or 15-inch pots, and furnish them with a trellis.

Water carefully after each shift, till the plants begin to get established, and when growing vigorously they may be watered freely. From the time of starting

until now the temperature, if possible, ought to be 65° at night, allowing a rise of 10° by day with sun-heat, and, as April advances, it may be increased to 70°, and even, during the daytime, to 80°, and on very hot, sunny days, some slight shading material should be applied. Shut up the house early in the afternoon, syringe, and in hot weather keep all available surfaces moist. Great attention must now be paid to the young growths. Securing fine threads from the trellis to the roof of the stove, twist the growth once round the trellis, and give each a thread to which it may be attached; and, as the shoots grow, widen the threads proportionately till they begin to set their bloom. Look carefully after back "breaks," and assist them to lay hold of threads in the same manner; for, when well treated, they produce good bunches of flowers. Let us now presume that the plant has some fine flowers upon it, and that many more are showing themselves. If wanted for exhibition, or for moving to some other house, carefully cut the threads to which the plant will have attached itself, like a Runner Bean, and place the shoots around the trellis, arranging the bunches of bloom to cover, say, three parts of the trellis. In the course of two or three days, the foliage will be as upright, and look as fresh as if the

plant had always been trained around the trellis; it should now be taken out of the plunging material, allowed to remain where it is for a week or ten days, and then it can be taken to an intermediate house which will harden it if wanted for exhibition. Dipladenias are subject to mealy bug, and great attention must be paid to keep them clear of this pest. Therefore, examine them every morning, during the growing season, when placing the young growth around the threads. As regards soil, the best is two parts light turfy loam, two parts turfy peat, one of cowdung—two or three years old, free from worms—and one of silver sand. To this add a good sprinkling of broken sandstone, or broken crocks, about the size of nuts, according to the size of the pots to be used. The loam and peat, when broken up, should have the finer portions taken out with a half-inch sieve, retaining none but the roughest for potting. Before each shift prepare the soil, and place it in the stove a day or so previously to using it, and avoid taking the plant outside when about to shift it into another pot; on the contrary, arrange for re-potting it inside the house. The following sorts are well worth growing, provided there is convenience for doing so, viz., amoena, the flowers of which are somewhat light in colour, but are

produced in abundance one after the other on the stalk; boliviensis, a distinct kind with rather smooth foliage, and flowers very delicate in colour; crassinoda, now superseded by the following kinds—amabilis, insignis, and Brearleyana, the last surpassing all the rest in colour and texture of flower, which is rich crimson, a colour which deepens with age.

J. W.

Acalypha marginata.

Ruscus androgynus (the Canary Island Butcher's Broom).—This is one of the most effective of all climbing

plants for a conservatory or winter-garden; but hitherto it has been rather difficult to procure. Cuttings of it refuse to strike, and division is scarcely more successful in the majority of cases. It is, however, easily propagated by means of seeds, if these can be procured; and, only the other day, we saw about a hundred healthy little plants of it in the St. John's Wood Nursery, which had been raised in this way, the seeds having been imported. This plant does well at Kew, and there are fine specimens at the Crystal Palace, and also in the old Botanic Gardens at Chelsea. Its pinnate leathery foliage is very durable, often lasting fresh for two or three months after being cut. When well established in a deep rich soil, it grows rapidly, the young growth resembling that of Asparagus.—B.

ACALYPHA MARGINATA.

To the myriads of fine foliage plants which have been introduced of late years this is a welcome addition. The leaves, as regards size, resemble those of *A. tricolor*, but the markings, in which their chief beauty resides, are of a character wholly different from those of that variety. In the present case, the centre of the leaf is brown, around which is a distinct margin of rosy-carmine about a quarter of an inch in width, and the surface is entirely covered with little hairs, which add considerably to its beauty. This plant,

of which we have seen fine specimens in Mr. Williams's nursery, at Holloway, belongs to the Spurge-worts, an Order comprising upwards of a hundred species, which are more or less distributed over all tropical and sub-tropical regions, but the head-quarters of which are in South America. A goodly number are annual, but the great mass are perennial plants, having much the appearance of Nettles, and readily known in the family from their Nettle-like leaves and the disposition of their flowers.

BALSAMS.

ALTHOUGH Balsams are a class of plants much looked down upon by many, perhaps because they are easily cultivated, yet few, if any, of our summer-blooming plants are superior to them in appearance, when they receive that care and attention which they deserve. Their beautiful double mottled flowers vary from the richest crimson to the purest white, and, when well grown, will last nearly three months in perfection. In order to have them in flower in June, July, and August, the seed should be sown early in March, in a pan with plenty of drainage, and filled with light compost. They should then be placed in bottom-heat, and when large enough to handle should be potted off into small 60's, plunged in a somewhat warm pit or frame, and placed near the glass, keeping them close for a day or two till they have taken hold of the soil. Every other day they should be turned, so that they may not become one-sided, and when they have filled the pots with roots—which should on no account be allowed to become matted—they may be shifted into 32-sized pots, in a compost consisting of equal parts of turfy loam, decayed cow-dung, and fine leaf soil. In potting, the balls should be kept well down, so as to have the lower shoots as near the surface as possible. Continue to keep them in bottom-heat and near the glass without water for a day or two till the stems become used to the soil about them; otherwise, they are liable to rot. After they are watered air may be given gradually in the daytime; and, when they have got hold of the fresh soil and are growing freely, a little air should be left on all night. By this time they will be ready for their final shift, which may be into sixteens or twelves, or even a larger size, but those named are the most suitable for general purposes. When shifted the side shoots should be pegged to the soil or tied to the rim of the pot to give the plant as pyramidal a shape as possible. When they are well in bloom they may be removed to the conservatory or greenhouse, and, when the pots are filled with roots, they may have a little manure-water twice a week, and once a day after the second week. Plants treated thus will, with care and attention, attain a height of 3 or 4 feet, and nearly as great a breadth. I once saw a Balsam, shown by an amateur at Bishop Auckland, Durham, 5 feet in height and of almost equal width; it was in a No. 1 pot. The lower shoots were pegged to the soil and had taken root, the plant appearing like a large one in the middle, with five or six smaller ones around it.

Eaglehurst.

W. W.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Brooks' Liquid Carbolic Soap.—Have any of your practical correspondents used this for the eradication of red spider, thrips, and other garden pests—and with what success?—H. M.

Spiræa palmata.—According to the "Florist," three plants have borne this name:—1. The Japanese plant, to which alone it belongs. 2. A North-American plant, with rose-coloured flowers, the *Spiræa palmata* of Linnæus, and which is properly the *S. lobata* of Murray. 3. The plant figured by Pallas in his "Flora Rossica," which is properly the *S. digitata* of Willdenow; a plant of Eastern Siberia, probably extending to China also. The true plant, then, being Japanese and not Chinese, it seems most probable that the species formerly grown in this country was the latter, *S. digitata*.

The Spring Beauty (*Claytonia virginica*).—This belongs to the *Portulaca* family. Its flowers are very modest and pretty—white, star-shaped, veined with pink, the five anthers of a deeper pink of extreme delicacy. It is 4 or 5 inches high, with but two narrow leaves growing half-way up the stem. The bulb, deep in the ground, is the size and shape of a Lima Bean, and of the colour and consistency of a Madeira root. There are two or three racemes to each, bearing from eight to ten flowers. The two ovate sepals, each with a little scallop in the top (emarginate), half envelop the round seed capsule, so that it resembles a bud, and is pretty after the flower has disappeared.—MR. CARMAN in "Moore's Rural."

White-flowered *Agapanthus*.—This is not, as stated at p. 507, perfectly hardy. Even with me, in the mild south of Ireland, it has been killed by a not very severe frost, which did no harm to the common blue variety.—W. E. GUMBLETON.

THE FLOWER GARDEN.

INDEX TO LILY NAMES.

By F. G. BAKER, F.L.S.

M. C. M. HOVEY, in his recent interesting communication to THE GARDEN on the American Lilies, having expressed a wish for an index to the various species, we re-produce this paper from the "Royal Horticultural Society's Proceedings":

Alphabetical List.

The numbers refer to the species. The names to which an asterisk (*) is attached are the adopted ones, the others are synonyms.

*albanicum, 26	*Fortunei, 8	*pomponium, 34
*album, 9	*fulgens, 14	*ponticum, 27

The following is a classified synonymic list of all the known Lilies, with their native countries, and references to the works where they are figured:

Sub-genus 1.—Eulirion.

Perianth funnel-shaped, horizontal or slightly drooping, its divisions broadest above the middle, spreading only towards the tip when fully expanded; filaments and style nearly straight.

1. *L. cordifolium*, Thunb.—Sub-species 1. *Cordifolium* proper.—Japan; figured in Zucc. in Sieb. Fl. Jap., fasc. 3, t. 13, fig. 2, and t. 14; Flore des Serres, t. 216. Sub-species 2. *Giganteum*.—Central and Eastern Himalayas, 5-10,000 feet; figured in Wall. Tent. Fl. Nep., t. 12, 13; Bot. Mag., t. 4,673; Flore des Serres, t. 771-2; Belgique Horticole, iii., t. 21.

2. *L. longiflorum*, Thunb.—Sub-species 1. *Longiflorum* proper.—Japan and China; figured in Bot. Reg., t. 560; Flore des Serres, t. 270; Lodd. Bot. Cab., t. 985; Bury Hexand., t. 8. Var. 1. *Eximium*.—Japan. *L. eximium*, Court., Spæ Mon., p. 14; Flore des Serres, t. 283-4. Syn. *L. Jama-juri*, Siebold et De Vriese Tuinbow Flora, vol. i., p. 319, t. 11. *L. longiflorum* Takesima, Duchartre Obs., p. 38. *L. longiflorum* Liu-Kiu, Siebold. Sub-species 2. *Neilgherrense*.—Neilgherries; figured in Wight Icones, t. 2,031. Syn. *L. tubiflorum*, Wight Icones, t. 2,033-4. *L. Wallichianum*, Wight Icones, t. 2,035, not Schultes. *L. neilgherrense*, Lemaire Ill. Hort. x., t. 353. *L. Metzii*, Steudel.

3. *L. Wallichianum*, Schultes fil.—Central Himalayas, 3-4,000 feet; figured in Bot. Mag., t. 4,561; Lindl. and Paxt. Fl., Gard. 1850, 120; Lemaire Jard. Fleur., t. 105-6; Flore des Serres, t. 612. Syn. *L. Batisua*, Ham. mss. *L. japonicum*, D. Don, not of Thunb. *L. longiflorum*, Wall. Tent. Fl. Nep., t. 29, not of Thunb.

4. *L. japonicum*, Thunb. Japan and Korean Archipelago.—Var. 1. *Japonicum* proper; figured in Bot. Mag., t. 1,591; Lodd. Bot. Cab., t. 438; Reich. exot., t. 88. Syn. *L. odorum*, Planch. Flore des Serres, t. 876-7. Var. 2. *Brownii*.—Japan; figured in Mielle Flore des Serres, t. 47. Syn. *L. japonicum*, Bury Hexand., t. 2.

5. *L. nepalense*, D. Don.—Temperate Central Himalayas; no now in cultivation. Var. 1. *Nepalense* proper; figured in Wall, Pl. Asiat. Rar. t. 291. Var. 2. *Triceps*.—Central Himalayas; not known in cultivation; figured in Klotzsch Reise Wald., t. 93. Var. 3. *Nanum*.—Central Himalayas; not known in cultivation. *L. nanum*, Klotzsch.

6. *L. candidum*, Linn. Sub-species 1. *Candidum* proper.—South Europe; figured in Bot. Mag., t. 278; Redouté Lil., t. 199; Flore des Serres, t. 735; Bury Hexand., t. 38; Reich fl. Germ., 445. Var. *Striatum* Hort; figured in Flore des Serres, t. 735. Sub-species 2. *Peregrinum*.—Never seen in a wild state, and now apparently lost from cultivation in this country; figured in Miller; Sweet Brit. Flow. Gard., ser. 2, t. 367; Hayne Arzne. 8, t. 27.

7. *L. Washingtonianum*, Kellogg.—California; figured in Gard. Chron., 1871, t. 142; Regal Gartenflora, t. 170; Flore des Serres, t. 1,975-6. Syn. *L. Bartramii*, Nuttall Herb.

Sub-genus 2.—Archelirion.

Perianth broadly bell-shaped, horizontal or slightly drooping, its divisions ovate or lanceolate, not distinctly clawed, spreading widely from below the middle when fully expanded; style declinate, and stamens much curved.

8. *L. tigrinum*, Gawl.—Japan and China; figured in Bot. Mag., t. 1,237; Redouté Lil., t. 395 and 475. Syn. *L. speciosum*, Andrews Bot. Rep., t. 586, not Thunb. Var. 1. *Fortunei*, Hort. Var. 2. *Splendens*, Hort.; figured in Flore des Serres, t. 1,931-2; Floral Mag. t. 509. Syn. *L. tigrinum* Leopoldi, Hort. Var. 3. *Lishmanni*, Moore Florist, 1873. p. 13 with figure.

9. *L. speciosum*, Thunb.—Japan; figured in Bot. Reg., t. 2,000; Zuch in Sieb. Fl. Jap., fasc. 3, t. 12 and t. 13, fig. 1. *L. speciosum*, var. *Kämpferi*, Bot. Mag., t. 3,785; Flore des Serres, t. 276-7. Syn. *L. lancifolium*, Hort., not Thunb. Stems purplish-brown. Var. 1. *Rubrum*, Masters in Gard. Chron., 1872, p. 1,522, Var. 2. *Album*, Masters l.c. Stems green. Var. 3. *Speciosum* proper. Var. 4. *Roseum*, Masters l.c. Syn. *L. speciosum*, Paxt. Mag. v., t. 1. Var. 5. *Punctatum*, Lem., Flore des Serres, under t. 277. Syn. *L. lancifolium*, Paxt. Mag. viii., t. 267, not Thunb. Var., Tametano, Zucc. Syn. *L. Broussarti*, Morren Mém. Acad. Roy. Brux., Feb., 1834. *L. speciosum* vestale, Hort. *L. eximium*, Hort.

10. *L. auratum*, Lindl.—Japan. Var. 1. *Auratum* proper; figured in Bot. Mag., t. 5,338; Flore des Serres, t. 1,528, 1,531; Ill. Hort. ix., t. 338; Revue Hort. 1867, t. 371. Syn. *L. Dexteri*, Hovey. Var. 2. *Wittei*, figured in Suringar in K. Koch Wochen. 1867, p. 294.

Sub-genus 3.—Isolirion.

Perianth broadly bell-shaped, quite erect, its divisions oblong-lanceolate, broadest about the middle, spreading in the upper half or third when fully expanded; stamens divergent on all sides from the centre of the flower.

11. *L. philadelphicum*, Linn.—Canada and Northern United States; figured in Bot. Mag., t. 519; Redouté Lil., t. 104; Lodd. Bot. Cab., t. 976; Bot. Reg. t., 594. *L. Andinum*, Nuttall. *L. umbellatum*, Pursh.

12. *L. medeoloides*, A. Gray.—Japan; not known in cultivation.

13. *L. Catesbæi*, Walters.—United States; figured in Bot. Mag., t. 259; Lodd. Bot. Cab., t. 807; Sweet Brit. Flow. Gard., ser. 2, t. 185. Syn. *L. spectabile*, Salisb. Parad., t. 5, not Link.: *L. carolinianum*, Catesby, not Michaux.

14. *L. bulbiferum*, Linn.—Sub-species 1. *Bulbiferum* proper.

—Austria, Sweden; figured in Jack. Austr., t. 226; Bot. Mag., t. 36; Redouté Lil., t. 210; Reich. Germ., t. 454; Regel Gartenflora, 1872, p. 231, with woodcut of bulb. Sub-species 2. *Croceum*, Chaix.—France, Switzerland, and North Italy; figured in Lodd. Cab., t. 784; Reich. Germ., t. 454. Sub-species 3. *Davuricum*, Gawl.—Through Siberia; figured in Regel Gartenflora, t. 740, and 1871, p. 231, with woodcut of bulb. Syn. *L. pennsylvanicum*, Gawl. Bot. Mag., t. 872; *L. spectabile*, Link; Reich. Icon. exot., t. 30; Regel Gartenflora, t. 349; *L. Buschianum*, Lodd. Bot. Cab., t. 1,628. Sub-species 4. *Thunbergianum*, Schultes fil.—Japan. Var. 1. *Thunbergianum* proper; figured in Lindl. Bot. Reg., 1839, t. 38; Maund. Bot., t. 158. Syn. *L. aurantiacum*, Paxt. Mag., 6, p. 127, with a figure. Var. 2. *Brevifolium*, Baker and Dyer Gard. Chron., 1872, p. 1,356. Var. 3. *Bicolor*, Moore Flor. Mag., t. 104. Syn. *L. pictum*, Hort. Sieb.: *L. aurantiacum*, Hort. Krelage. Var. 4. *Wilsoni*, Leichtlin. Syn. *L. pardinum*, Moore Flor. and Pom., 1861, p. 121, with a plate. Var. 5. *Alutaceum*, Baker and Dyer l.c. Syn. *L. Thunbergianum* aureum nigro-maculatum, Flore des Serres, t. 1,627. Var. 6. *Armeniacum*, Baker and Dyer. Var. 7. *Citrinum*, Hort. Wilson. Var. 8. *Sanguineum*. Syn. *L. sanguineum*, Bot. Reg., 32, t. 50; *L. biligulatum*, Hort.: *L. lateritium*, Hort. Var. 9. *Atro-sanguineum*, Baker and Dyer l.c. Syn. *L. hematochromum*, Lem. Ill.

Hort., t. 503. Var. 10. *Fulgens*, figured in Morren Spæe Mon., 29; Lemaire Ill. Hort., t. 422. Syn. *L. venustum*, Kunth Flore des Serres, t. 657; *L. fulgens* var. *staminosum*, Lemaire Ill. Hort., t. 1,422, is a double-flowered form.

15. *L. lancifolium*, Thunb.—Japan; a very little known plant, never brought into cultivation, perhaps a variety of the last. Figured in Mem. Acad. St. Petersb., 3, t. 3.

16. *L. pulchellum*, Fisch and Meyer.—East Siberia; figured in Regel Gartenfl., t. 284, fig. 2; Revue Hort., 1862, p. 131, with a figure.

17. *L. concolor*, Salisb.—China and Japan. Var. 1. *Concolor* proper.—China; figured in Salisb. Parad., t. 47; Bot. Mag., t. 1,165. Var. 2. *Sinicum*, Lindl.—China; figured in Paxt. Flow. Gard., vol. ii., misc. t. 193; Ill. Hort., t. 100; Flore des Serres, t. 1,206; Bot. Mag., t. 6,005. Var. 3. *Coridion*, Sieb. and De Vriese.—Figured in Sieb. and De Vr. Tuinbow Flora, vol. ii., p. 341, with a figure. Var. 4. *Partheneion*, Sieb. and De Vriese.

Sub-genus 4.—Martagon.

Perianth always drooping, broadly bell-shaped, its divisions lanceolate, broadest about the middle, not distinctly clawed, distinctly reflexed when fully expanded; stamens diverging much on all sides from the centre of the flower; and style declinate.

18. *L. martagon*, Linn.—Central and Southern Europe and Siberia. Var. 1. *Martagon* proper.—Figured in Bot. Mag., t. 893 and 1,634; Red. Lil., t. 146; Jacq. Austr., t. 351; Engl. Bot., t. 279, 3rd edit., t. 1,518; Reich. Ic. Germ., t. 451. Var. 2. *Hirsutum*, Miller. Syn. *L. Milleri*, Schultes. Var. 3. *Glabrum*, Sprengel. Var. 4. *Catanii*.—Dalmatia; figured in Visiani Fl. Dalm. Suppl., t. 3. Syn. *L. martagon* var. *dalmaticum*, Maly.

19. *L. maculatum*, Thunb.—Kamschatka, Manchuria, Japan, Russian America; figured in Mem. Acad. Petersb., 3, t. 5. Syn. *L. avenaceum*, Fisch. Maxim.; figured in Regel Gartenfl., t. 485.

20. *L. canadense*, Linn.—Canada, Eastern United States, and California. Var. 1. *Canadense* proper.—Canada and Eastern United States; figured in Bot. Mag., t. 800 and 858; Bury Hexand., t. 12; Flore des Serres, t. 1,174. Var. 2. *Parvum*.—California; figured in Kellogg Proc. Calif. Acad. ii., p. 179, t. 52; Regel Gartenfl., t. 725. Var. 3. *Puberulum*, Leichtlin, not Torrey.—California. Var. 4. *Walkerii*, Wood.—California.

21. *L. superbum*, Linn.—Var. 1. *Superbum* proper.—Eastern United States; figured in Bot. Mag., t. 936; Red. Lil., t. 103; Bury Hexand., t. 36; Flore des Serres, t. 1,014-5. Var. 2. *Carolinianum*, A. Gray.—Eastern United States; figured in Mich.; Bot. Mag., t. 2,280; Bot. Reg., t. 580 (not Catesby). Syn. *L. Michauxii*, Poiret; *L. Michauxianum*, Schultes fil.; *L. autumnale*, Lodd. Bot. Cab., t. 335. Var. 3. *Pardalinum*.—California; figured in Kellogg Proc. Calif. Acad. ii., p. 12. Var. 4. *Bourgæi*, Baker.—British Columbia.

22. *L. columbianum*, Hort. Leichtlin.—Oregon and British Columbia. Syn. *L. Sayii*, Nuttall mss.; *L. canadense*, var. *parviflorum*, Hook.; *L. canadense*, var. *minus*, Wood.

23. *L. Humboldtii*, Roezl and Leichtlin in Duchartre Obs., p. 105.—California; figured in Regel Gartenflora, t. 724; Fl. des Serres, t. 1,973-4. Syn. *L. canadense*, var. *puberulum*, Torrey Bot. Whipple, p. 90; *L. Bloomerianum*, Kellogg Proc. Calif. Acad., iv., p. 60; *L. californicum*, Hort. Angl.

24. *L. Roezlii*, Regel Gartenfl., t. 667.—California, Utah. Syn. *L. canadense*, var. *Hartwegii*, Baker in Gard. Chron., 1871, p. 321.

25. *L. monadelphum*.—Var. 1. *Monadelphum* proper.—Caucasus and Asia Minor; M. Bieb. Cent. Ross., t. 4; Bot. Mag., t. 1,405; Reich. Exot., t. 89; Regel Gartenfl., t. 733; syn. *L. Loddigesianum*, Schultes fil.; Lemaire Jard. Fleurs., t. 204; Paxt. Flow. Gard., t. 58; Flore des Serres, t. 507-9. Var. 2. *Szovitsianum*.—Asia Minor; figured in Fisch. & Lall. Regel Gartenfl., t. 536; Flore des Serres, t. 507-9. Syn. *L. colchicum*, Steven.

26. *L. carniolicum*, Bernh.—Lombardy, Austria, and Turkey. Var. 1. *Carniolicum* proper.—Same distribution; figured in Reich. Ic. Germ., t. 990. Syn. *L. chalcedonicum*, Linn. in part; Jacq. Fl. Austr. Suppl., t. 20. Var. 2. *Albanicum*.—Albania and Transylvania.

27. *L. ponticum*, L. Koch.—Asia Minor; not known in cultivation.

28. *L. polyphyllum*, Royle.—Western Himalayas, temperate region; not known in cultivation. Syn. *L. punctatum*, Jacquemont, Duchartre Obs., p. 77.

29. *L. chalcedonicum*, Linn.—Greece, Ionian Islands, Asia Minor; figured in Bot. Mag., t. 30; Red Lil., t. 276; Reich. Ic. Germ., t. 453 (not of Jacquin).

30. *L. pyrenaicum*, Gouan.—Pyrenees; figured in Red Lil., t. 145; Reich. Ic. Germ., t. 992. Syn. *L. flavum*, Lam.

31. *L. callosum*, Sieb. & Zucc.—Japan and Loo Choo; figured in Fl. Jap., t. 41.

32. *L. testaceum*, Lindl. Bot. Reg., 1843, t. 11.—A garden hybrid between *candidum* and *chalcedonicum*; figured in Paxt.

Mag. Bot., 1843, p. 221; Flore des Serres, t. 39; Regel Gartenfl., t. 349. Syn. L. excelsum, Hort.; L. isabellinum, Kunze.

33. L. Leichtlinii. Hook. fil.—Japan. Var. 1. *Leichtlinii* proper. L. *Leichtlinii*, Bot. Mag., t. 5,673; Ill. Hort., t. 540; Flore des Serres, t. 1,736; Belg. Hort. 1869, t. 11; Floral Mag., t. 509. Var. 2. *Maximowiczii*. L. *Maximowiczii*, Regel Gartenfl., t. 596. Var. 3. *Pseudo-tigrinum*. L. *pseudo-tigrinum*, Carrière Red. Hort. 1867, p. 410, with a figure; Regel Gartenfl., t. 664.

34. L. poponium, Linn.—Lombardy and the south of France. Syn. L. *pomponium*, Bot. Mag., t. 971; Reich. Ic. Germ., t. 991. L. *angustifolium*, Mill. L. *rubrum*, Lam.

35. L. tenuifolium, Fisch.—Siberia. Syns. L. *pumilum*, Red Lil., t. 378. L. *linifolium*, Hornem. L. *puniceum*, Sieb.

The group *Notholirion*, including L. *roseum*, Wall. (*Thomsonianum*) and L. *Hookeri*, Baker, must rank under *Fritillaria*, not *Lilium*, as it has a slender filiform stigma and tunicated bulbs, and these are the best marks of technical difference between the former and latter genus.

Meconopsis Wallichii.—Mr. Williams, of Ormskirk, is right respecting the colour of the flowers of this species, which are of a purple-blue. It is figured in the "Botanical Magazine," plate 4,668. *M. nepalensis* is the only known Indian species having yellow flowers. However, it is, of course, quite within the range of possibility that the flowers of the same species vary in colour. *M. aculeata* has rich lilac-purple flowers, and is probably the hardiest of all, except *M. horridula*, as it grows at an altitude of 11,000 to 15,000 feet in the Western Himalayas. Altogether there are six Indian species known, two of which, *M. simplicifolia* and *M. horridula*, have one-flowered radical scapes—all the others have a panicked or racemose inflorescence. The colour of the flower of *M. robusta*, the sixth species is unknown. None of them appear to grow below an elevation of 8,000 feet, and *M. horridula*, an almost stemless plant, with lanceolate, very prickly leaves, and blue-purple flowers, about 1½ inches in diameter, was gathered by Dr. Hooker at an altitude of 17,000 feet.—W. N. H.

Thermopsis montana.—This is considered by Dr. Gray to be but a variety of *Thermopsis fabacea*, which has long been favourably known as an ornamental border perennial, and from which it differs chiefly in its narrower and longer foliage and stipules. Like the older plant, it has bright yellow pea-like flowers, in terminal spikes 3 to 4 inches long, and trifoliate leaves clothed while young with silky pubescence, but glabrous in its mature growth. It is said to be superior as a garden plant to the *T. fabacea*. The seed has been received from Utah; it occurs also in California, and in the Rocky Mountains of Colorado, in bushy places by mountain streams.—T.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Dracæna indivisa in Flower in Cornwall.—This is now finely in bloom in Mr. Simmons' Nursery at Falmouth. It has been planted out ten years and is about as many feet in height. The flower-spike is about 3 feet in length, and 2½ feet in diameter, and, although but few of the flowers are as yet fully open, they emit a powerful and pleasant perfume. Of the perfect hardiness of this plant in many parts of the west of England, no doubt, I think, need now be entertained.—JOHN D. MITCHELL.

Climbing Roses after Flowering.—Your correspondent (see p. 494) will not be able to keep climbing Roses clothed with shoots at the bottom if the tops are permitted to grow unpruned from year to year. If the top shoots of *Maréchal Niel* are stopped now, new shoots will most likely break near the bottom, and thus the plants may become clothed throughout with young wood. In other respects it should be left alone. All Roses should be pruned yearly; the rampant growers, as a rule, more sparingly than others. *Maréchal Niel* ought to bloom in autumn, and generally does so, although not always, and never so freely as during the summer.—ARTHUR W. PAUL, *Waltham Cross*.

Blue Asphodel (see p. 504).—I would venture to suggest that the proper name of the plant described in Mr. Ruskin's book as a blue Asphodel is that species of *Camassia* usually known and sold under the name of *C. esculenta*, but which my friend Mr. Elwes informs me is not really that variety, but some other, the specific name of which I at this moment forget. When recently on a visit at Miserden House, I saw both varieties of *Camassia* growing side by side, and the true *esculenta* had a taller spike of much smaller and paler-coloured flowers than the variety hitherto known to me under the name of *Camassia esculenta*.—W. E. GUMBLETON.

Large-flowered Everlasting Pea (*Lathyrus grandiflorus*).—I noticed the other day, in Windsor, a line of this Pea some 15 feet in length, dividing the fore courts of houses there. It was coming into bloom, and promised to be a beautiful mass of flower. Would it not be possible to secure a cross between this, the best of the *Lathyrus* family, and our garden Sweet Peas? It is probable that whilst one would furnish perfume, the other would give increased size of flower. *Lathyrus latifolius* also deserves greater attention than it at present receives. It is one of the best porch or arbour plants with which I am acquainted, and it only needs to have its roots "kept at home" to make it annually a beautiful decorative plant.—D.

Destroying Mole Crickets.—Having ascertained the hole inhabited by the mole cricket, pour in water till it is quite filled to the top, then immediately pour on the surface of the water some oil, which, as the water sinks, will go down into the hole and effectually kill the cricket by stopping his breathing.—C.

THE LIBRARY.

DESTRUCTIVE INSECTS.*

WE have already noticed this "Report" (see p. 510), so far as regards the chinch bug and the Rocky Mountain Locust; but a few additional remarks still remain to be made upon the former only, which, of the two, is the least known. The chinch bug is a small bug, named *Micropus leucopterus*. It lays its eggs at the roots of the plants, and the young, when hatched, remain for some time under ground, sucking the sap from the roots. They are at first pale yellow, turning successively into bright vermilion, and afterwards dusky in front and red behind, but in all stages having a pale band across the middle of the body. The perfect insect is usually black, with more or less of white upon the wings. It feeds almost exclusively upon Grasses and cereals, sucking their juices, and it is only when they are in great numbers that they do much mischief; but, when out in its myriads, "those who have not seen the ground alive and red with its young, or the plants black with the dark bodies of the more mature individuals; those who have not seen the stout Corn stalk (Maize stem) bow and wilt in a few hours from the suction of their congregated beaks, or a Wheat field in two or three days rendered unfit for the reaper; those who have never seen the insect marching from field to field, or absolutely filling the air for miles, can form no adequate conception of its destructive powers." Seeing that so much mischief has of late years been done by the unintentional introduction of injurious insects into new countries, through the rapid and wide-spread commercial intercourse among foreign nations, it is natural to look with suspicion upon any pest that is ravaging the territories of our neighbours. When your neighbour's house is on fire it will not do to say it is none of your business. The silk worm disease, the Vine Phylloxera, the Cabbage butterfly, and the Colorado beetle, are examples that will occur to everyone of the application of this maxim; and it may be wise to ask ourselves if there is any chance of the chinch bug coming over and settling amongst us. It cannot well come in the egg state, for the eggs are laid on the roots of the living plants underground; it cannot well come in the larval state, for the larva lives upon the green leaves of the growing plant; but it is not quite so clear that it may not come in the perfect state. Mr. Riley tells us that such as survive the autumn, when the plants on the sap of which they feed are, for the most part, so dried up or withered and decayed as to afford them little or no nourishment, pass the winter in the usual torpid state, under dead leaves, under sticks of wood, under flat stones, in Moss, in bunches of old dead Grass, or weed, or straw, or often in Corn stalks and Corn shucks. Is there, then, anything very unlikely or improbable in their passing the winter in granaries, or under heaps of Wheat or Corn, or what is to prevent their being carried over in the cargoes of Wheat that are annually imported into this country from every part of America? We can see nothing; only, the fact is that they have never come, although they have been well known for upwards of a century. The chinch bug is mentioned in the old "Records of the Revolutionary War," as prevailing in North Carolina, and Kirby and Spence made everyone aware of its destructive properties in their "Introduction to Entomology," which was published in 1828. This is reassuring; for if we have been yearly exposed to its introduction ever since grain was first imported from America without its ever coming, we may comfort ourselves with the reflection that as we have escaped in the past so we may in the future. Still, we must remember that both increased importation and increased rapidity of transit add largely to the bugs' chances, so that the fear of it can hardly be dismissed as visionary. It has not occurred to Mr. Riley to speculate on the chances of such an introduction, but he does give us his opinion upon the question as regards the Colorado beetle, which has now reached the Atlantic sea-board. He does not look upon the alarm taken by some European governments as wholly without foundation, but sensibly points out that much less restrictive measures than absolute prohibition of importation would be quite sufficient. It is obviously much less adapted for accidental transport than the chinch bug. Like it, it is only in the perfect state that its

* "Riley's Seventh Annual Report on the Noxious and other Insects of Missouri," 1875.

introduction is possible, unless some one were out of malice pre-pense to take to bringing over living Potato plants; and, in the perfect state, it passes the winter under ground, and is bigger than a horse bean, while the chinch bug hibernates in any crevice, or under any protection, and is no larger than the common bug. As our readers possibly know, Paris green is a successful remedy for this pest; but its use for that purpose has given rise to a good deal of discussion. Some regard it as injurious to the Potato plant; others as injurious to the soil; and many are opposed to its use from its danger as a poison to individuals. Mr. Riley discusses these various matters, and also the best mode of applying it. Curiously enough, the insect itself is said to be poisonous under certain conditions. Not that its bite is poisonous, but that the fumes from those that are destroyed by scalding have all the effects of irritant poisoning. The poison must, however, be present in infinitesimally small quantities, for it has been proved by experiment that individual specimens can be crushed even into a raw sore with impunity; and it is only when large quantities have been collected together and scalded that these poisonous effects have been felt. Mr. Riley's "Report" deals also with other insects besides those we have noticed, such as the canker-worm, the Apple-borers, the Phylloxera, &c.; but the principal part of it is occupied with the Colorado beetle, the chinch bug, and the locust. The work does him great credit, both as a careful observer, an accurate recorder, and able writer.

A GARDEN HAMMOCK.

A HAMMOCK well "triced up" forms an excellent resting-place on board ship, more especially in a heavy gale, but it is vastly inferior to the hammock (hamaca) of South and Central

A Garden Hammock.

America and the West Indies, which, in the opinion of those who have tried both, is a more perfect lounge than any sofa that has yet been made. These hammocks, whether made of palmetto fibre or of cotton—they are exported in large numbers from Manchester—should be fully 11 feet from "clew to clew," and when spread out laterally should have a width of quite 6 feet. Two good sized trees, about 10 feet apart, should be chosen, from which to suspend the hammock; in each of these, at a height of 6 feet from the ground, fix a stout screw-hook, having an iron thimble on it, round which the "lanyards" or ropes should be passed—this thimble preventing the rope being cut by the hook. Each end of the hammock is then suspended, and it is then lowered down until it is some 16 inches from the ground. Spread it well out sidewise, place a pillow in it for your head, and the veritable hammock of tropical America is ready for occupation. It is usual to have it lowered to within 18 inches from the ground, as you are thus enabled with a touch of the foot to set it swinging when you please. Hooks should always be used, as they render it possible to bring everything within doors at a moment's notice. A. L. T.

"La poire."—The most elegant of our flowering shrubs or small trees is the wild Shad-flower or Service berry (*Amelanchier canadensis*), a tree rarely exceeding 25 feet in height. The flowers, large and white, blooming in April and May, in terminal racemes, make it conspicuous among the yet naked forest. The berry, ripening in June, is highly esteemed by the inhabitants of British America, where it is known by the name of "La poire."—"Cultivator."

APPROACHES.

THESE, in my opinion, are often too narrow, the roadway in cases being barely sufficient for two carriages to pass each other. If one thing more than another foreshadows the style and pretensions of a mansion it is the approach, which should always be in keeping with both mansion and park. A road of less width than 16 feet is too narrow where the mansion is large and the approach of considerable length; and where the mansion is palatial in extent and appearance 20 feet is not too wide, especially if a portion of the approach can be seen from the house. In such case a narrow roadway dwindles into a mere track, which ill assorts with a grand gateway and a noble front. A modern landscape gardener and author gives 14 feet as ample width for the largest places, and 9 or 10 feet for those of moderate-size, and thinks it better that carriages should take the Grass with one wheel in passing than have the road a foot or two wider—a bicyclist would feel uncomfortable on such a track. The prospect from the front of one of the grandest residences in England is marred by an approach of this kind. From a spacious front entrance and noble gateway an approach some 12 or 13 feet wide, extending a mile or more in a straight line, appears like a mere track, and all the more so inasmuch as it runs through a level and sparsely-wooded park. In such a case, a width of 20 or 25 feet would not have been too much, and if even this had been supplemented by a clear margin of Grass 30 feet wide on each side, backed by a line of trees for half a mile from the house, it would only have corresponded fitly with the imposing structure to which it led. As regards the planting of avenues, tastes differ. Some like the trees to be close to the road, so as to over-arch it completely, which is not objectionable under some circumstances, as by planting suitable trees and pruning them properly, a pleasant leafy arcade may be formed. The Gothic arch looks best. A remarkably fine example of this kind is to be seen on an approach to a church not far from Lichfield. The road is perfectly straight for about a hundred yards, as far as I recollect, and the trees, which meet thickly overhead, have been trained by pruning into a perfect Gothic arch of considerable height, so that the avenue looks like a green cathedral aisle, with an ivy-clad church tower and porch at the end of it. When the avenue is an open one, however, the trees if there be any, should be well removed from the roadside. Rows of trees are, of course, not always necessary nor even desirable in some cases, but the appearance of an approach is much improved, and proportion better secured when the route is furnished with trees, though they may be planted irregularly. The approach to Dalkeith Park is a good example of breadth of treatment. The entrance and gateway are spacious, and the drive follows the natural level of the ground with easy recesses and curves, while the wood which lines the road on both sides is thrown back perhaps a hundred feet or more, if I remember rightly, the greater part of the way. A well-appointed equipage on an approach of this kind is a highly ornamental object, and is seen to advantage, while its occupants experience a sense of freedom, and enjoy the prospect, both of which would be marred in a roadway shut in by lofty trees on each side. Among the tall Spruce plantations in the neighbourhood of Worksop are to be seen drives that chill the traveller by their dark dreariness, though the roads are not of the narrowest description; the country, however, is flat and monotonous, and tall Spruce and Scotch Firs shut out the view on all sides. One serious objection to wide approaches is the expense of keeping them in order. The traffic only keeps the middle of the road free from weeds; hence the wider it is the greater will the amount of space on each side be which has to be kept clean. This should not, however, be allowed to outweigh the desirability of having the approach in keeping with the mansion. Cleanliness depends a good deal upon the making of the road. A macadamised road requires by far the least keeping; but many are uneasy if their approach is not annually gravelled afresh; and thus a loose bottom, and constant employment for the Dutch hoe, is the result. On one estate with which I am acquainted not a spadeful of gravel is allowed to be put on the roads, which were macadamised many years ago, and are now in the most perfect order—smooth and hard from side to side in summer and winter, and requiring exceed-

ingly little attention to keep them clean. This is the kind of road for a park; but they must be made properly at the first, or rather I should say skilfully, for it is the putting on of the metal, and not altogether its depth, which secures permanency. Now that stones are broken by machinery, road metal of the most durable kind can be had almost as cheap as gravel. In some of the ironstone districts the slag is broken up and sold for the purpose, and it is one of the hardest materials that can be employed. Macadam was able to construct excellent roads over a morass with only a few inches of broken stones properly put on. Mistakes are often committed by people unacquainted with road-making. In some cases I know of the kitchen garden thoroughfares are made 15 inches deep, with large stones in the bottom, broken stones next, and gravel above all. This makes an excellent walk, but not better than if an average depth of 3 inches only of broken stones had been put on, at perhaps one-half the expense. I have seen quite as good a walk made of sifted coal clinkers, put on 4 inches deep, and hid with a sprinkling of gravel. Whether an approach has to be kept constantly gravelled or not, it should at all events have a macadamised bottom, in which case it does not matter whether the foundation is hard or soft. Thus, supposing we had to make the road through a park of soft loam, it would be unnecessary to move more than the surface sod to a depth of 3 or 4 inches, and, having levelled the bottom evenly, and allowed it to settle where inequalities had been made up, it would only be needful to put on the broken stones to a depth of about 6 or 7 inches in the centre, and less at the sides, leaving a crown in the middle, just sufficient to throw the water off readily. The stones should be broken into pieces about 2 inches in diameter; and, in putting them on, they should be scattered, shovelful after shovelful, to the required depth, and not laid on in heaps, as is generally done by workmen; indeed, the usual plan is to empty the load in the middle of the road, and simply level it down where it lies. Trifling as this matter may appear, it is of importance; for, when road metal is laid on in hillocks—in barrowfuls, for instance—the mass is unequal in density, the small and the large pieces not being mixed regularly; and, after setting, the road becomes lumpy and uneven, an evil which is not easily remedied afterwards. A road made as here described, and of the above depth, or even less, if the bottom is somewhat firm, will naturally bear any amount of traffic for a long period of years; and for the heaviest work, from 8 to 10 inches of metal are sufficient. Of course, on an approach it will be necessary to surface the stones with clean gravel of some kind, for the sake of appearance and smoothness; but no more is required than is sufficient to fill up interstices on the surface. When the road is new the stones get kicked out by the horses' feet; these should not, however, be raked off, but pressed into their holes again with the back of a rake, and in a short time the crust will settle down to an even surface, which even the horses' hoofs will not disturb, and which will be easy to keep clean and trim. The chief utility of a macadamised surface consists in its impermeability to water; the water being thrown off at the sides, for the most part, and the bottom being kept dry, which, if soft, would work up, and be also injuriously affected by frosts; hence, the importance of making the road properly at first.

J. S. W.

Size of the Wellingtonia at Bitton.—The following measurement of my Wellingtonia may interest you. It was planted in 1855. Height, 39 feet; outside circumference of branches, 63 feet; circumference of trunk near the ground, 7 feet 6 inches.—H. N. ELLACOMBE, Bitton.

Hardiness of the Hemlock Spruce.—The common Hemlock Spruce is one of the most hardy of all evergreens, being found growing wild far into North British America, where from 30° to 40° below zero is not an uncommon temperature in winter; still this tree is frequently killed outright by 20° or 30° less cold in the gardens about New York. A very severe winter in the Middle States is pretty certain to be destructive to this naturally very hardy evergreen, consequently we must consider mere temperature as only one of the destructive agents, and not alone the cause of such losses.—"Moore's Rural."

Grafting Rhododendrons: C. T. S.—Rhododendrons may be grafted either in autumn or spring. Saddle-grafting is the best method. The grafted plants should be kept in a close house with gentle heat until the union is established, and then be gradually hardened off before planting out. We need hardly add that grafting of this kind is by no means profitable to private growers. It is one of the many things best left in the hands of nurserymen, who possess every facility for such operations; and, therefore, succeed in cases in which amateurs would most probably fail.

Pears Destroyed by Grubs: L. O.—The Pears were so injured in transit that we could not detect the grubs. Gather together all the injured fruits and burn them; unhappily there is no other available remedy.

OXFORD COLLEGE GARDENS.

THE gardens belonging to the Oxford Colleges would hardly satisfy the expectations of a gardener. If, for example, he expected to find that the "Walks of Christ Church" would lead him through borders of varied floral beauty, he might be disappointed to see no flowers whatever, save those which have been sewn by the milliner in the bonnets of the *placens uxor* who leans upon her lord the Don, or in the hat of her pretty daughter, for whom two hundred graduates sigh, when the moon is up. And when he left the grand old Elms of this Broad Walk, the handsome Planes, and the interesting Zelkond; when he had admired, in Dr. Pusey's garden, the scion of the first Fig tree, introduced into England from Aleppo, by Dr. Pocock, in 1648, and in Canon Heurtley's, the fine old Oriental Plane; when he had visited the "Gardens" of Exeter, from which our sketch is made, of Trinity, St. John's, Worcester, Wadham, and Magdalen Colleges, he would say that the title was a misnomer, and that the classic appellation of grove, or the pretty term of "pleasaunce," was more appropriate to those glorious old trees, those shrubberies, and walks, and lawns. Youth is impulsive, and in our Oxford days it brings a desire to "chivy" one's friends, ride on their backs, and roll over them, which no severity of study, no solemnity of architecture can repress, and which is very adverse to floriculture. Wherefore, ever since the Carmelite or White Friars settled themselves, where Worcester College now stands, some 600 years ago, and began to make, as Wood the historian tells, pleasant walks and groves, the gardens of Oxford have been mainly composed of trees, Grass plots, and gravel, umbrageous in summer, screened in winter, alike suitable for the constitutional, or the meditation of potent, grave, and reverend "seniors," the herbage soft, when the weather was fine, and the walks dry when the weather was wet, for their peripatetic performances, and also a suitable arena in which the juniors might disport themselves and do no harm. And yet, though the flowers are few, there is a great dignity, and grace, and beauty about these college gardens. The trees are, in many cases, magnificent specimens, and the contrast between their bright green foliage and the solid masonry of stone is very picturesque and attractive. There is every sign of care and of good taste. If we miss the brightness of the flowers, we are not offended by modern gaudiness, or by that old *barberism*, which, in the year 1628, as we see from old prints, produced the royal arms and the arms of the college, with the initials of Charles the First and William of Wykeham, done in clipped Box and Yew in the gardens of the New College. In the Botanic Gardens the gardener will find much to interest him. These were opened in 1632, Inigo Jones being the architect, and the illustrious John Tradescant the gardener, though it is doubtful whether he ever came to fulfil the duties of his appointment. Evelyn was here in 1654, and was shown the Sensitive plant as a marvellous treasure, "also Canes" (for scholastic purposes), "Olive trees, and Rhubarb." The great Linnæus came in 1736. There is an excellent collection of medicinal and herbaceous plants, and a few tolerably good examples of trees of interest; for instance, a *Paliurus aculeatus*, *Pyrus domestica*, *Salisburia adiantifolia*, *Corylus Columna*, *Gymnocladus canadensis*, *Betula pontica*, *Ornus europæa*, &c., all of which were most likely planted by Prof. J. Sibthorp, author of the "Flora Græca." And near to Oxford there is not only the nursery of Mr. Prince, famous for his Roses on the seedling Briar, but there are numerous sheltered spots in which the citizens and college servants gladden their eyes and refresh their spirits when work is over; and where some of the best specimens of the queen of flowers and others of her ladies-in-waiting are tended in their season by skilled and patient hands.

B. N. C.

Roses and Rose Lovers.—June is the paradise of Roses. In this month they break forth into unparalleled splendour. All Rosedom is out in holiday apparel; and Roses white and black, green and pink, scarlet, crimson, and yellow, striped and mottled, double and single, in clusters and solitary, Moss Roses, Damask Roses, Noisette, Perpetual, Bourbon, China, Tea, Musk, and all other tribes and names, hang in exuberant beauty. The air is full of their

AN OXFORD COLLEGE GARDEN.

fragrance. The eye can turn nowhere that is not attracted to a glowing bush of Roses. At first one is exhilarated. He wanders from bush to bush and cuts the finest specimens until there is no room or dish for more. So many Roses, and so few to see them! What would not people shut up in cities give to see such luxuriance of beauty? How strange that those who have ground do not gather about them these favourites of every sense! The air and soil that nourish Nettles and Thistles, Plantain and Dock, would bring forth Roses with equal kindness. There is enough ground wasted around country-houses to furnish root-room for a hundred kind of Roses without detriment either to fruit trees or ornamental trees. Men admire them when they see them in a friend's house; they are always pleased to receive a lapful as a present to their wife or mother or daughter; but it does not enter their head that they, too, might have Roses to give away. Roses are easy of culture, easy of propagation, requiring almost as little care as Dandelions or Daisies. The wonder is that every other man is not an enthusiast, and in the month of June a gentle fanatic. Floral insanity is one of the most charming inflections to which man is heir! One never wishes to be cured, nor should any one wish to cure him. The garden is infectious. Flowers are "catching," or the love of them is. Men begin with one or two. In a few years they are struck through with floral zeal. Not bees are more sedulous in their researches into flowers than many a man is, and one finds, after the strife and heat and toil of his ambitious life, that there is more pure satisfaction in his garden than in all the other pursuits that promise so much of pleasure and yield so little. It is pleasant to find in men whose hard and loveless side you see in society, so much that is gentle and beauty-loving in private. Hard capitalists, sharp politicians, grinding business men, will often be found, at home, in full sympathy with the sweetest aspects of Nature. One is surprised to find how gentle these monsters often turn out to be! Here is the man whom you have for years heard described, in all the newspapers, as a spectacle of wickedness or a monument of folly. You are, by some convulsion of Nature, thrown into his company and travel for days with him. To your surprise his manners are gentle, his conversation pleasing, his attention to all about him considerate. This must be artifice. It is a veil to hide that hideous heart of which you have heard so much. You watch and wait. But watching and waiting only satisfy you that this supposed monster is a kind man, with a world of sympathy for beautiful things. And when, in after months, you have been at his summer-house, and know him in his Vineyard and his garden, you smile at yourself that you were ever subject to that illusion which is so often raised about public men. A man is not always to be trusted because he loves fine horses, or because he follows the stream or hunts in the fields. But if a man that loves flowers, and loves them enough to labour for them, is not to be trusted, where in this wicked world shall we go for trust? A man that carries a garden in his heart has got back again a part of the Eden from which our great forefather was expelled.—H. W. BEECHER.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Coleworts.—Coleworts should now be sown. The ordinary varieties of small-growing Cabbages are frequently designated Coleworts, but the true varieties of the latter are very different, and much superior for autumn and winter use to Cabbages. Their small size admits of their being planted closely and in places not adapted to the ordinary kinds of Cabbage. Coleworts are also very hardy, seldom suffering, except in the severest winters. In amateurs' gardens, where the space devoted to vegetable crops happens to be limited, there is frequently at this season an insufficiency of ground vacant for the different winter and spring crops. Where this is the case, the late kinds of Broccoli and Cabbage for winter should at once be put in a nursery bed of rich prepared soil of a loose nature, that will adhere to the roots when they are moved; in this put out the plants 9 inches asunder, giving them (if the weather is dry) a good soaking with water, and not allowing them to want it afterwards. Here they may remain for a few weeks, until ground is cleared from other crops. They will not ultimately make such large plants as those at once planted out where they are to remain, but they will do much better than such as are allowed to grow closely in the seed-bed, where they get stunted, or become weak and leggy. As early Peas, Cauliflowers, and Lettuces are over, at once clear the ground, and plant with winter crops. Amateurs will find that upon prompt action here depends a great deal of success, and in this the market gardeners may with advantage be imitated. It is no uncommon thing to see with them whole acres covered with Lettuce and Cauliflower, which in the space of a few days are swept away, and their place occupied with something else. This system of continually keeping the ground occupied without rest entails the necessity of correspondingly

heavy dressings of manure; but the advantage of much greater produce from a given space, together with its increased fertility, are all on the side of this system. Plant out successional crops of Celery, and, if the weather is dry, give it plenty of water.

Parsley.—A little Parsley should now be sown on well-prepared rich ground. Sow in rows 15 inches apart. This will not be disposed to run to seed so soon in the spring as that which was put in earlier. Thin out the early sown plants, leaving them 9 or 10 inches asunder. If this is attended to in time, there will be little to fear from canker at the root, which usually occurs when the plants are over-crowded. Where Parsley is given sufficient room, it can be kept through the winter with half the trouble, and much greater certainty, than where it is starved and weakly.

Carrots.—Thin out the principal crops of these, allowing them room in proportion to the size of the variety grown. Large-growing long kinds require more space than the small Horn varieties. A sprinkling of soot over the plants will help to keep aphides from their tops, and also grubs from their roots. Amateurs will find that there is nothing better than slight dressings of soot over most vegetable crops that are at all subject to the attacks of insects, as, independently of the manurial assistance it affords the plants, it renders them less liable to become a prey to pests of all kinds.

Seakale.—As advised early in the spring, Seakale can be grown either from pieces of the whip-thong-like roots, cut in lengths of 6 or 8 inches, which is the best method; or from seed sown early in April. If, by the latter method, the seeds are as usual put in four or six together, in rows at intervals of half a yard apart in the rows, and a like distance row from row; they will require to be thinned to a single plant in each place, and the ground between should be kept well hoed, so as to destroy weeds. By this method, in good, deep, well-enriched soil, a portion of the plants will be strong enough for taking up to force during the coming winter, the weaker ones being allowed to remain for another year. The great advantage in growing Seakale from root cuttings is that the plants have the start of those grown from seed, the greater part making strong roots the first summer. Nearly all that are allowed to stand a second season will throw up flowers, which must be cut away, or they completely prevent the plants making strong crowns; and, under any treatment, these plants that have so thrown up a flower-stem are not so good as they otherwise would be; even when cut out as soon as it makes its appearance it causes the root to form several crowns, which are individually weaker, and not so good for forcing as a plant with a single strong crown. The old system of growing Seakale in rows a yard apart, the plants being the same distance asunder in the rows, and forcing it in the bed under pots made for the purpose and covered with leaves or other fermenting material, is extravagant in every way, both as regards the ground it occupies, the cost of pots, and the amount of labour involved. Forced in this way, it also often has an earthy taste. In the cultivation of this vegetable amateurs should remember that it is a marine plant, and, like its congeners, is fond of moisture and manure of a saline character. Those who reside on the coast cannot do better than dig into the soil, where it is grown, plenty of rotten sea-weed; where this is not at hand a good dressing of refuse salt—4 or 6 ozs. to the square yard—applied through the growing season, but not so as absolutely to touch the plants, will be found highly beneficial to the crop.

Fruit.—Late varieties of Strawberries, such as British Queen and Elton Pine, if the weather is dry, should be well watered, or they will not swell off their fruit to a handsome size. Where it is the intention to prepare Strawberries in pots for forcing, as soon as runners are formed they should be layered in small pots, which plunge in the ground, or they are continually requiring water. Place the runners at a joint, on the surface of the soil in the pots, and to secure them put upon each a stone about the size of a hen's egg. All they require until they are well rooted is sufficient water to keep the soil moist.

Peaches and Nectarines.—Go over these, and if the fruit is still too thick, remove more, as also superfluous shoots, but, on no account, take away too much leaf, for, in the season, this is worse in its effects upon the trees than the opposite extreme of neglecting to dis-bud them. Continue to use the garden engine or syringe regularly two or three times a week, wetting the undersides of the leaves. If this is attended to, little injury will be done by thrips and red spider—the worst enemies these fruits are affected by, and which not only materially injure the present crop, but weaken the trees, thereby seriously affecting them in after years. These fruits will be benefited by mulching the ground with half-rotten dung. This is easily applied where the borders are not cropped with anything over the roots. Where Strawberries are grown on a Peach border the mulching they have received will assist to keep the soil moist.

Asters and Stocks.—Successional plants of these may be planted out, and by putting in a later batch the bloom may be kept up further in the season. Asters, especially, are so useful for

cutting that it is desirable to have them as late as they can be had. Bi-annual stocks of different colours, especially purple and red, should at once be sown. These fragrant plants are not so much grown as they deserve to be, although their culture is very simple, requiring nothing more than to be sown in ordinary soil, and as soon as large enough, pricked out in patches of three or four in the herbaceous borders, or where they are wanted. Wallflowers, Sweet Williams, and Foxgloves may yet be sown, and if well attended to will make fine plants for next year. Dig and afterwards rake the soil quite smooth; then sow the seeds thinly, covering them slightly with sifted soil; if the weather should be dry, water with a fine-rosed pot, so as not to wash the seed bare. Afterwards keep the seedlings sufficiently thin in the bed to allow them to grow stout, and keep them clear from weeds.

Lawns, &c.—Where there are many Dandelions and Plaintains, and they were got out earlier in the season, they will again spring up, and should be at once cut. By constantly operating on them, they will gradually die off. The late showery weather will cause weeds to make their appearance on walks, and advantage should be taken of the gravel being softened by the rain to hand-weed, which can be done more easily when damp than at any other time.

Roses in Pots that have flowered under glass, and are now turned out-of-doors, should be well attended to, for upon this depends their capacity for flowering well next season. These plants, if well-managed, will go on improving for a number of years. After blooming, if they require larger pots, they should be shifted on; good yellow loam, made rich with rotten dung, being used, with the addition of sand in keeping with the nature of the soil. Any that do not require potting will be benefited by the surface-soil being replaced with an inch or two of new. They should then be plunged out of doors in an open situation in coal-ashes and regularly attended to with water; whilst making active growth, they will be assisted by the application of manure-water once a week. Keep them clear from aphides and red spider by using the syringe frequently; and should mildew make it appearance, dust them with sulphur, or syringe with water in which flowers of sulphur has been mixed and well stirred. Two ounces to the gallon is a good proportion, and the mixture should be allowed to stand for a couple of days; after which it can be used in a clear state. It is particularly necessary to keep this parasite in check during the summer season on pot Roses; for, if allowed to take possession of them, it not only does them much harm, but is sure to appear as soon as the plants are started during the coming winter, at which time it will be much more difficult to deal with. Roses that have got well established in pots, and are properly attended to in the manner described, will flower much more satisfactorily than those that are forced for the first time.

Flower Garden and Pleasure Grounds.

The late copious rain-fall has been of much benefit to recently-transplanted trees and shrubs, as well as to newly turned out bedding plants; and the soil in most cases will now be found to be favourable for the pegging-down of Petunias, Verbenas, and similar plants. All such trailers may be fastened to the soil with facility by means of short pieces of bast, which, after being passed round the shoot, should be thrust into the soil with a wedge-like pointed stick; an operation which should be persevered in as the plants continue to grow, until the surfaces of the beds are fairly covered. In all cases, when pegging-down is inapplicable, let the plants be supported when necessary by stakes. Box-edgings to walks and drives may still be cut; and, where edgings consist of any other kinds of plants, such as Daisies, Thrifts, &c., they may now be cut in, or otherwise reduced to any desired extent. Edgings of Grass should be frequently mown, and, on each occasion, should have the edging shears applied, to prevent the Grass from growing into the gravel. Where walks, however, happen to wind through dense masses of shrubs, or under the shade of trees of any sort, it is always difficult to keep Grass, or edging plants of any kind, in a healthy condition; and, in all such cases, it is advisable to use an edging-tile of some sort, which, having generally a neat appearance, is much to be preferred for such situations to an edging consisting of unhealthy plants. Keep the surface of gravel walks free from weeds of all kinds. Moss may generally be eradicated by giving a good dressing of salt, which, on some kinds of gravel, not only appears to give increased solidity to the walk, but also improves its colour. Should the walk, however, be edged by turf, or plants of any kind, care must be taken to prevent the salt from coming in contact with them. To be safe, indeed, it should not be placed closer to them than from 6 to 9 inches. A period of dry, hot, settled weather should also be chosen for the application, or it will have little, if any beneficial effect. Sow the various kinds of Brompton Stock and German Wallflowers—if not already done. Wallflowers come quite double from seed; but, where it is desired to

increase the finest kinds, cuttings should be employed, and put in now, under hand-glasses, in a shady situation. All spring bedding plants should have what little attention they require, in order that they may be found in thoroughly good condition when they will once more be required to furnish the flower-beds. If old plants of the various species used for this purpose were carefully divided when they were removed, and afterwards planted in the reserve garden, all they will now require will be an occasional supply of water during dry weather, and the keeping of the soil in which they are planted free from weeds, &c. If this division, however, did not take place then, it ought to be attended to now, or as soon as possible; and old plants of such species as the Arabis, Aubrietia, Daisy, the variegated Dactylis, Helleborus, Hepatica, Myosotis, Primula, Saxifraga, Sedum, the variegated Tussilago Farfara, Violas, &c., should be carefully divided into small portions, which should be planted in good, light soil, well watered, and shaded for a few days, should the weather become hot and dry. This may be effected by inserting among them a few twigs of the common Laurel, or similar material, which should be removed as soon as the plants have become established. Treated in this manner, they will soon become fine plants, and when required in the autumn will be found capable of producing an immediate and desirable effect in the flower garden.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Indoor Fruit Department.

Vines.—If not very carefully looked after now, red spider will quickly multiply, for no kind of weather is more favourable to its increase than that which usually occurs in July and August. Dryness at the root often assists its development more than dryness in the atmosphere, and Vines on light soils are more liable to be affected than those in moist stiff loam. It is, however, bad management to allow the pest to develop from excessive dryness; and unprotected outside borders, filled with roots, must be well watered, for, where the bottom rests on plenty of drainage, the soil becomes quickly parched. Where rough manure is not regarded as unsightly, the surface of the border may receive a coating to the depth of 6 inches or more of this material in a moist state; and the soil may then be forked over, and left, rough water being applied plentifully after the manure has been laid on. This may be done with advantage to all Vines bearing fruit, excepting those upon which it is ripe, or nearly so. When the soil is somewhat exhausted, the manure is of assistance in perfecting the crop, especially where it is at all excessive. All young Vines, planted at any time this season, will have their roots very near the surface. The slightest check in any form will be injurious to them for years to come. Pot Vines intended to supply the earliest fruit next spring, should now be widened out, and placed in a position where they will be fully exposed to the sun throughout the greatest part of the day. It must not be thought because the growth of the Vines is perfected, that insects may do as they like, for to neglect them now is to undo what has already been done. On very hot days, it is often necessary to water Vines having their pots well filled with roots, twice or three times a day. The foliage should never be allowed to flag for want of water.

Pines.—Avoid a strong artificial heat in any Pinery when the sun-heat becomes powerful early in the morning. A small fire lighted at 8 p.m. and allowed to burn out prevents the temperature from falling below 65° throughout the night, and more than this is not necessary. Provision should be made for taking off and potting the general stock of suckers. Plenty of fibrous loam should be broken up, and whatever plunging material is to be used should be placed in a convenient position for using. Be careful to shade fruit almost fully swelled, or it may ripen prematurely and be wanting in juice and flavour.—J. MUIR.

Action for Damage Done by Fowls to a Garden.—At the Bloomsbury County Court the other day, before the presiding judge, the case of *Beaman v. Cummings* was heard, in which the plaintiff, residing at 53, Lawford Road, Kentish Town, sued the defendant, residing at No. 55 in the same road, for damage done to flowers in the plaintiff's garden by the trespass of the defendant's poultry, and for money paid by the plaintiff in respect of the following particulars—namely, 5½ dozens of choice Carnations, costing £2 6s., and 18s. damage done to the plaintiff's garden, and for the gardener's time in replacing the same. The defendant said every precaution had been used by him to restrain his fowls, but even if any damage had been done, 8d. each for a common flower like a Carnation was a preposterous price. The judge thought this was not so, and was of opinion that, as the defendant had not properly restrained his poultry from committing depredations, he must pay for the damage done. Judgment was accordingly given for the full amount claimed with costs of attorney and one witness.

"SPORTS" IN PLANTS.

MR. C. M. HOVEY, the able and experienced horticulturist of Boston, has had something interesting to say on this subject to the Horticultural Society of Massachusetts. He says—"What is a natural sport? To most horticulturists and cultivators of experience this may appear a simple question, but by numbers of persons it is not so well understood. A natural sport is a variation or peculiar change of any part of a plant from its normal state. Take for instance the Camellia, or Japonica, as it is often called. Here we have the old Double White (*alba plena*), a Chinese variety, imported into England so long ago as 1739, and since then extensively propagated and disseminated all over Europe and America. Yet it is still the very same flower it was in 1739, so far as we know ourselves, or can learn from descriptions, paintings, or books. It has never been anything else. If, however, you or I had a plant which should, upon one particular branch, show a flower of a different form or colour, that particular flower would be denominated a 'sport.' So, too, if the leaves were to assume a different shape, or the branches some peculiar form, that would be also a sport, because, in either instance, it has departed from its original type. Such a flower or branch is, therefore a 'natural sport,' and so considered in these remarks. It is somewhat extraordinary, when we notice the character and importance of these sports, that so little has been written upon the subject. In the very hasty manner in which I have been enabled to look through the works of various authors I find that it is scarcely mentioned at all. Mr. Knight, in his numerous physiological and horticultural papers published from time to time in the 'Transactions of the Royal Horticultural Society,' does not speak of sports. Loudon, in his various exhaustive volumes on trees, plants, and shrubs, has little or nothing to say of them. Lindley, in his 'Theory of Horticulture,' does not notice them, and M'Intosh, Thompson, and other authors, do not give us any information upon the subject. Indeed, it is only in the periodical works upon horticulture, and scattered through many volumes, that much can be learned, and this in the main recorded of only a few particular sports. When we reflect a moment upon their importance, and consider how much our pleasure grounds and gardens, our greenhouses and conservatories, have gained in valuable additions through these sports, we are surprised that so little has been treasured up regarding them. The fact that we know so little of the cause of these sports is probably the reason why the record of their production is all that can be found. It is only within a few years that they have assumed any prominence, though, undoubtedly, they have existed for a long period. The very curious variegated trees from Japan, though probably some are from seed, are, many of them, undoubtedly sports, for it is not probable that so many seedlings should be precisely like the parent, except in the colour of the leaf. Loudon, in describing one of the very dwarf forms (*Abies clanbrasiliana*) of the Norway Spruce, states that it was said to have been found at Belfast, but, he remarks, that to him "it was very doubtful whether such a stunted variety as this was ever found in a bed of seedlings; we think it more probable that it is a continuation by cuttings of one of those bird-nest-like monstrosities that are occasionally found on all trees;" in reality, a sport, though he does not use that word. As we have stated, little can be learned about sports in books, and we are driven to form our own conclusions regarding them. That they do take place on original plants there is no doubt, but it would seem that this tendency to sport is greatly increased by continued reproduction from seed. We have stated that, so far as we know, the old Double White Camellia has, in nearly a century and a half, never sported. Yet, when we look at that incomparable and most exquisite of all flowers, the Camellia fimbriata, a perfect counterpart of the Double White in leaf and form, except that its petals, pure as the driven snow, are as delicately cut as the most delicate of fair hands alone could cut them, throwing a charming fringe around each petal, we think this, too, was a sport saved by some observant and enthusiastic cultivator of the Flowery Kingdom, and bequeathed to us as a token of the care which that heathen nation has ever bestowed upon one of the most beautiful handiworks of the Creator. The Azalea is another Chinese plant which, at the present day, is the most "sportive" of all that we possess; in fact, it has become so to such a degree, that a name signifies but little. Sometimes the flowers of striped varieties are all white, sometimes red, and at others parti-coloured, and many of our varieties are perpetuations of these sports, some of which continue true and others go back to the original. As to the cause of these sports we have little to say. Our only theory is that, having undergone so many cross fertilisations, they have become, as we often say, "somewhat mixed," for the older varieties of the large-flowered, or rather large-leaved kinds, of the Phœnicea and alba type remain very true, and sports among them are exceedingly rare—indeed, we ourselves do not know of one. I trust that the few instances I have mentioned of the origin of

sports will show you the importance of observation. No doubt many interesting additions might have been made to our variety of plants, had the cultivators of fifty years ago been as numerous or unremitting in their labour as those of recent years. The number now who are on the look out for every sport is legion, and the yearly additions to our catalogues show that they are not idle."

POSIES FOR THE POOR.

"A GOOD SUGGESTION.—A correspondent writes to us:—'At this season, when all the gardens are full of the loveliest and sweetest blossoms, there are—as at every season—hundreds of poor people in our London Hospitals with whom time passes very heavily, and whose sad, sick hearts would be cheered beyond measure by the sight and smell of our commonest garden flowers; and there are, I am equally sure, hundreds of kind-hearted men of business who would willingly bring up each a bunch of flowers, once or twice a week, to town, and drop them into a large basket placed conveniently at the railway station. Each hospital might have a basket, or the flowers could be shared out from a big one. Nearly every hospital is close to a station. Many poor sick people—regular Cockneys—hardly know what a flower is.'"

"Splendid bouquet you've got," cried young Citizen Brown
To old Citizen Briggs, in a train up to Town.

"Some young Party this evening to take to the play,
Or a ball? Mr. Briggs, Sir! I say, Sir, I say!"

Said his elder, "It isn't at all what you think;
So you've got no occasion to smirk and to wink.
I am not a young puppy—these bristles are white—
Home and early to bed is my custom at night.

"No; these flowers from my greenhouse and garden will go
To a place where they'll serve more for use than for show;
To a hospital ward, where the Lily and Rose
Will improve the condition of things for the nose.

"A suggestion of late in my paper I read
Of this cheap contribution to cheer the sick bed.
As a thing to be done, Sir, my fancy it caught,
So in practice, you see, I've put *that* happy thought.

"The smell of Syringa, Carnation, and Pink
May help raise up the spirits which in sickness sink,
And Geranium, and Scabious, and Lychnis, supply
Some refreshment for many a poor patient's eye."

"Mr. Briggs, Sir," said Brown, "the ideas you impart,
They do honour alike to your head and your heart:
You experience, of course, that enjoyment which should,
And does, I have no doubt, attend doing good.

"I remember some rhymes upon acts of the just
Say they smell sweet and blossom, although in the dust;
And your nosegay, for hospital patients designed,
Though I can't quite repeat them, has brought them to mind."
—"Punch."

THE POWER OF SOIL, AIR, AND VEGETATION TO PURIFY SEWAGE.*

By ALFRED CARPENTER, M.D.

I HAVE taken the subject of the practical power of soil, air, and vegetation to purify the sewage of towns for our consideration as distinguished from that which may be called the theoretical view of the question. It is acknowledged on all hands that the filtration of sewage, however concentrated, or however diluted through soil, will effectually remove all the objectionable matter which is contained in the water; that is, filtration will remove all organic matter from the water, and allow it to pass away perfectly purified, provided the filtration is continued long enough or the filter renewed often enough, and the thickness of filtering material be fairly adequate for the purpose. The theory of sewage purification by soil is the foundation of sewage irrigation, but the power of soil is not everlasting; its power to extract organic matter has a limit, and if the action of the filter be continued after that limit has been reached, there is a cessation of purification, and nuisance and its contingencies are inevitable. The water which passes through the filter may be absolutely less pure than before filtration was effected. Soils, however, vary in their power to abstract organic matter; some being more competent than others to effect the object in view; some are powerful enough to purify water if it passes through a foot or two of material, as is the case in the ordinary water-filter; others do comparatively little, and soon lose their virtue by saturation. I am not, however, about to discourse upon the capacities of soils, but simply to ask you to concede the point, and then conduct you to the second term of my proposition, viz., the power of air to assist the process. If a filter is continuous in its operation it soon fails, but if its action is inter-

* Paper read at a monthly meeting of the Association of Medical Officers of Health.

mittent, if the soil in use is allowed to run dry, and the interstices which naturally exist in it, and which, whilst in action, are filled with water—if those interstices are allowed to become re-charged with air, the power of the filter is restored, and purification is again effected. There is an oxidisation of the organic matters contained in the interstices of the filter; the arrested organic matters become organic salts, and pass away when the filter is used again, dissolved in the water as nitrates and nitrites, and, if looked for, afford evidence of a so-called previous sewage contamination. In themselves they are harmless in the quantities in which they are usually found in filtered water. This is the principle in operation in the plan which is now finding favour under the name of downward intermittent filtration. The organic elements in the sewage, which are dangerous in their recent form, are changed into harmless salts and are comparatively lost to cultivators. It tends to produce in the long run an imperial bankruptcy by casting away into the sea a valuable matter which has to be recouped to us as a nation by purchases from other countries. Still, intermittent downward filtration effects a present object, and can be made applicable for the purpose of purifying sewage in those places in which it is found impossible to bring to bear upon the matter the third term of my proposition, and which is the most powerful agent of the three in the series, viz., vegetation. A filter requires rest to allow of the access of oxygen for the purposes of oxidisation, but the true principle of sewage utilisation is, for that oxidisation not to take place at all, but that the organic matter which is arrested by the soil should be taken up into its natural storehouse, made to revert into the formed material of plant-life at once, rather than to change into a chemical salt which has to be decomposed again by the vital power of the plant, re-absorbed into its juices, and so brought back to organic life by a roundabout process, instead of that direct one which Nature provides; for there is no doubt that plants infallibly extract every particle of matter of organic origin existing in the atom which has nitrogen in its composition, that passes within reach of their rootlets. It will thus be observed that I have considered my communication to be one which is to show the practical power of soil and air combined with vegetation to purify sewage. Analyses give no countenance to the idea that land will in time become sick of sewage, provided the proper weight of crops is taken from it, as compared with the amount of sewage which is passed on to a given area. If fifty tons of produce are annually obtained from every acre of land upon which 5,000 tons of town sewage have been poured, a ton of produce for every 100 tons of sewage, it will be found that a proper balance has been struck, and all manurial matter has been extracted which is at all likely to be obtained. It is found, however, in practice, impossible to get the fifty tons a year. The produce of Rye Grass land gives on the average about forty tons per annum; and, at the end of three years, the land is broken up and planted with some other crop, as Mangold, or Cabbage, or both, or it is market gardenized, and during the time it is thus cropped the sewage is sparingly applied. Thus the fresh cropping takes out of the soil the matters which were not abstracted by the Rye Grass, and the balance is restored without the possibility of danger arising to the health of the district around. I wish it, however, fairly to be understood that I do not advocate the use of effluent water from sewage land as household water, but I do contend that it may be admitted into any watercourse without injury to the residents, and without damage to fish. The commissioners on pollution of rivers propose to allow any water to go into a running stream which does not contain more than two parts by weight of organic carbon in 100,000, or '30 parts of organic nitrogen. I have a report of the examination made of effluents from most of the sewage lands in the kingdom, from which it may be seen that in every case the water has complied with the conditions laid down by the commissioners. Let us now refer to the financial returns. We have about 460 acres of land under cultivation. The valuation, as to produce, which was made in March last year, was £4,732 2s. 9d. The valuation now is £5,020. During the past year we have received in hard cash £7,256, which, with present valuation, gives a return of about £20 per acre, as obtained from the land by sewage cultivation, not allowing for working expenses.

Dr. Letheby, in opening the discussion on this paper, thought that Dr. Carpenter had disposed of three great questions in somewhat a too charming and easy manner. The three great points to consider were the power of vegetables to assimilate organic manure. The safety in case of sewage-grown vegetables, and the nuisance arising from the vicinity of sewage culture. Whether organic matter must pass into the mineral stage before it regains the vegetable state is a question, and the power of the plant to utilise organic matter is a most important one.

Dr. Voelcker: It is a very important question whether vegetable life is sustained by organic or mineral food. At one time humus or the organic matter in soils, was regarded as the sole source of

terrestrial food of plants, but the humus theory, which has done so much mischief in retarding progress, he thought, had received the final death blow by the wonderfully clear and most conclusive argumentative writings of Liebig, and he quite agreed with that great chemist; but the luxuriant development of the crops usually grown on cultivated lands depended mainly upon the available mineral food present in the soil, and not on its organic matter—indeed, he did not know a single fact which supported the view according to which plants live and grow vigorously upon the organic matters of the soil or manure, and not upon the mineral portion of the soil or the saline and mineral constituents of the manure. It had been established beyond controversy that the really essential elements of plant food were mineral and not organic substances; and he was decidedly of opinion that the constituents of sewage had to become mineralised before they could benefit growing crops. In porous and well-drained soils, and in land readily permeated by atmospheric air, the conversion of organic refuse matters into purely mineral compounds proceeded with great rapidity; and this, by the way, was one of the causes why sewage culture succeeded better on light land resting on a porous sub-soil than upon stiff clay soils upon imperfectly drained sub-soils. On stiff clay land the decomposition of the animal refuse matter proceeded much more slowly than upon porous, light, and sandy soils. Hence it was that heavy clay land was generally manured in autumn, whilst light land was more beneficially manured in spring; for if ordinary farmyard manure were applied to the land in spring on stiff clay lands, there would not be sufficient time to convert the manure into mineral elements of plant-food, and light crops would be the result. He would further state in support of this view, that on soils not readily penetrated by air, organic matters were positively injurious, and the healthy and vigorous growth of all produce, and the destruction of organic matter, and the production of available mineral plant-food in porous soils, proceeded with great rapidity. He would quote in proof of this the interesting experiments of Boussingault and Léwy, who had shown that the air in a cultivated soil invariably contains less oxygen than the air above it. A portion of the oxygen in fact was consumed by the organic matter in the soil, and its place was taken by carbonic acid, resulting from the combination of the carbon of the organic matter with the oxygen of the air. According to the nature of the soil and the time of the year, and the way in which it had been treated as regards manure, the amount of carbonic acid in the air of the soil may increase to over eight per cent. and that of oxygen recede to less than twelve per cent., and invariably it is less than twenty-one per cent. by volume. For instance, on analysing the air present in a light sandy soil, recently manured and after rain, Boussingault and Léwy found:

	By volume.
Carbonic acid	9.74
Oxygen	10.35
Nitrogen	79.91
	100.00

In another sandy soil, unmanured, the air contained:

	By volume.
Carbonic acid	0.93
Oxygen	19.50
Nitrogen	79.57
	100.00

These experiments show plainly that common dung and similar refuse matters are really burnt up or oxydised in porous soils with great energy, and rapidly converted into mineral plant-food. In another experiment the same chemists found in the air in a stiff clay soil:

	By volume.
Carbonic acid	0.66
Oxygen	20.04
Nitrogen	79.30
	100.00

Showing that here the combustion of the organic matters in the land proceeded more sluggishly; and, I may add, on such land the produce is generally more scanty than on a porous well-aërated soil, plentifully supplied with mineral food, amongst which I include nitrates.

Dr. Corfield agreed with Dr. Carpenter in everything he had stated almost entirely. Dr. Carpenter had been moderate in quoting from analysis, because in many cases the soil contains more nitrates than were given. In winter plant life was at its lowest; and in no case was the effluent water in such a satisfactory state in the spring before vegetation was in the most active state. We have first to purify the sewage and to oxydise whatever ammonia remains from the plants. If the water passes over the soil, you cannot be sure in winter that the water has been purified. There is plenty of time to oxydise all sewage matter if it passes through the soil. With regard to the

imputed nauseous character of sewage where it is passed through the ground it has not been found offensive.

Dr. Letheby: One of the prime elements to consider is the fitness of the soil, the quality, quantity, and time that sewage is put on. It is commonly supposed that any soil will do for sewage, but that is a mistake. Purification is due not to the soil but to the absorbing character of the roots of plants; some say, therefore, that a clay soil is the best for purifying purposes, and others argue that a light silicious soil is the fittest. These are practical considerations, and in discussing them we should know all the circumstances.

Dr. Carpenter, in reply, said, I have proved that plants can live on organic matter by experiments I made in feeding some with beef tea, on which they thrive beautifully, and immediately; whilst those plants fed with mineral matter required time. I passed over the subject of soils, which is an important subject, but that of vegetation is more so. Damage, danger, and nuisance, are ideal terms, not facts. Our land takes the sewage of 165 persons per acre, and I challenge anyone to eat the produce and give any adverse criticism that will bear testing. Sewage culture requires great attention and care as regards details; but, if properly done, it presents a scientific solution of the sewage problem. As to filtration, it is necessary to do this on clay lands in winter; but it is also necessary to have crops in a proper state to assimilate the sewage. We have been flooded on the breaking up of frosts, but that is a common occurrence in many places. With regard to the death-rate of the district; the population in close proximity has been rapidly rising, and 15·7 is not high considering the want of water and other circumstances. In some of the surrounding parts the water supply is so bad from impure wells that the poor prefer taking our effluent water. Lastly, with regard to the detriment of property, an acre of land adjoining that to which sewage was applied was recently sold for £1,095. A few years since land close to it was sold for £100 per acre.

AN IMPROVED GARDEN FRAME.

THE accompanying illustration represents a handy little garden frame, which cannot fail to prove useful, not only to amateurs, but also to professional gardeners. It was introduced to my notice by Mr. Mitchell,

An Improved Garden Frame.

gardener at Knossington Hall, near Oakham, who informed me that he has found such frames extremely handy for protecting seed beds, winter vegetables, and spring flowers. They measure 4 feet 6 inches in length, and 3 feet in breadth; one of their chief merits consists in the sashes being moveable. As shown in the illustration, they are hinged at the back, and may be folded together like the cover of a book, and lifted out of the grooved supports if desired. The glass is inserted entirely without putty, and iron sash-bars may be used instead of wooden ones, which conduces somewhat to their durability. These useful and convenient little frames are the invention of Messrs. Anderson & Waite, of Melton Mowbray.

B.

Budding Standard Thorns.—In hedgerows, where it is desirable to form standard Thorns, the present is a good time to commence the preparatory work by driving in long, stout stakes, to which two or three of the best shoots may be secured, and, if sufficiently long by the autumn, they may be budded with the different improved kinds, amongst which are Paul's Scarlet and the variegated-leaved single white, which makes a charming scented object, its silvery leaves enhancing the beauty of its appearance.—CHEVALIER.

Turf Plant for Hot Countries.—A new turf plant, for hot, dry countries—*Lippia ægyptiaca*—is favourably spoken of. M. Delchevallerie, an experienced gardener who lives in Egypt, was surprised on seeing the verdure of this plant, which he met with on one of his excursions, and he planted it in the gardens under his care. It spreads rapidly, rarely flowers, and it is of a beautiful dark green. Hot and dry countries are, however, by no means badly off for plants that cover the ground with green in summer; the Ice Plants and green Sedums have been proved to answer admirably for this purpose in the sunniest parts of Italy.

THE KITCHEN GARDEN.

THE NEW POTATO DISEASE.

ON the first appearance of curl in the leaf of my Snowflake Potatoes, I felt no alarm, as I considered the evil to be only of a temporary character, but, on seeing the leaves decay and drop off, I bared the stems down to the sets, where I found a small cluster of young Potatoes attached to the base of the stem, the largest being about the size of a Broad Bean. The stems looked black, and appeared to be fast decaying, and around some of them, clustered in great numbers, a spider-like insect. Growing side by side with the Snowflake are the Eureka, Brownell's Beauty, and Compton's Surprise, a pound weight of each of which was planted on the same day, and all treated alike in every respect; Brownell's Beauty and Compton's Surprise have shown slight symptoms of curl, but no decay; Eureka is growing with a rapidity and vigour rarely observed in any Potato; and such plants of Snowflake as have escaped disease are also growing with great vigour—in short, nothing can be said in praise of this Potato which it does not deserve. Its appearance above ground is simply perfect, and I would fain hope that the disease which now threatens it is local rather than constitutional. The Early Rose and Eureka are the only two American varieties with me that are entirely free from curl. Bresee's Peerless, a most vigorous grower, showed symptoms at one time of becoming much affected. I hear from different cultivators, who have reared sets of Snowflake in pots, that no symptoms of disease have shown themselves in their case (see also p. 491). Like myself, they planted their sets out in the ordinary way, in the early part of April. The plants belonging to one grower (an amateur) have wholly disappeared, like those referred to in the Horticultural Society's Gardens at Chiswick.

Alnwick.

J. T.

I herewith send you two specimens of what seems to be a kind of Potato disease—perhaps the one referred to in your "Notes of the Week" (see p. 500). In the sample marked No. 1 you will see that the haulm is very much affected with it, but not regularly throughout the several rows; on the contrary, it appears only here and there at present, though in general the whole crop looks unhealthy, the growth being stunted, and the leaves curled or shrivelled. The sample marked No. 2 is a portion of the haulm that has died quite back. I have just dug up the root and find the set (a whole Potato) quite rotten, with eight very small Potatoes attached to it. I dug up another close by, which was dying away in like manner, with the set (half of a Potato) quite sound. If not like the disease noticed at Chiswick, what is it, and what is its probable cause?

JOHN H. HOWARD.

Bath Road, Exeter.

[This is the same disease as that which appeared at Chiswick and elsewhere.—A. M.]

Snowflake Potato.—As your three correspondents, "J. T.," Mr. Hobday, and Mr. Tillery, have evidently given certain treatment to the sets of this Potato after severing them from the tubers, and with different results, the treatment which I have given might, perhaps, be advantageously compared with their's. I cut my 1 lb. of tubers into thirty-three sets or eyes, and planted them directly between my rows of Raspberries; they were hoed up in due course, and have not been attended to since. I have always admired the healthy appearance of the haulm, which is, as yet, quite free from blemish, spot, or curl, and the plants have the appearance of yielding a good crop, as not one of the thirty-three eyes has failed. Now, as this Potato is being extensively patronised, I would suggest that a comparison of results be made at the time of digging, each grower to state, in brief, certain particulars, such as time of planting, number of eyes planted, number grown, appearance during growth, how planted, how long after the eyes were cut out, actual weight from the 1 lb. planted, weight of twelve or twenty of the largest tubers dug, number of Potatoes dug (under 1 or 1½ inches not to be reckoned in the number or weight), when dug, time from planting to digging, with any other remarks that might in the interim suggest themselves.—JOHN H. HOWARD, Bath Road, Exeter.

— I have no reason to complain of Snowflake, as even minutely cut sets of it have done well from my own saved seed; but 1 lb. of

imported seed of Eureka, cut up into fifty sets, has left about two-thirds blanks. It is important to remember that this so-called new disease is chiefly confined to the Rose family; and although symptoms of it show themselves in other American kinds, they only become partially developed. I conclude, therefore, that the Rose section was not worse diseased than other American kinds last year; but that, owing to the soft texture of that section, the tubers became much sooner developed than those of other kinds; and that whilst they could only just muster strength enough to throw up a weak growth, the others could push most of their growths well above ground before decomposition set in.—ALEX. DEAN, *Bedfont*.

American Potatoes.—In addition to those mentioned by Messrs. Hooper (see p. 421), we have also Thorburn's Paragon, Carter's American Breadfruit, American Red, Gleason's Late Callao, Early Callao, and others, the names of which I cannot call to mind, making, probably, in all, some two dozen kinds. As the question "What are American Potatoes?" is of special interest in relation to the forthcoming International Potato Show, it is well to remind readers that, whilst the prizes offered by Messrs. Hooper and Messrs. Carter are for any American kinds—that is, of course, for the handsomest samples—the prizes offered by Messrs. Bliss & Sons are for kinds introduced into this country since the beginning of 1874, so that growers will have to select the three best kinds out of about nine or ten varieties.—ALEX. DEAN, *Bedfont*.

Early Potato Culture in the Channel Islands.—During late years a remunerative industry has made rapid progress in the islands round which Victor Hugo cast the glamour of romance in "The Toilers of the Sea." Owing to the difference of climate, the Potato reaches maturity earlier in the season than those grown in most parts of England, and consequently find a ready market in London, where they successfully compete with the produce of southern Cornwall, the Scilly Islands, and Normandy. Every year the quantity sent to England from Guernsey and Jersey increases, so that the islands promise to become Potato gardens before many years elapse. Almost all the inhabitants who possess a patch of ground cultivate the tuber, which is also largely grown under glass. In these hot-houses the Potatoes are ready for digging at the beginning of spring, when they sell for as much as 2s. or 2s. 6d. a pound to the wholesale dealers in Covent Garden Market. Some idea of the extent already reached by this new industry may be formed from the fact that during two months lately Jersey alone exported 22,623 tons, estimated to be worth £215,000. It is estimated from trustworthy data that the cultivation of this vegetable returns annually nearly £7 10s. for each acre of ground in the island.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Sutton's Matchless Parsley.—This vigorous handsomely curled variety is well worth attention. When seeds of such kinds as this and Carter's Fern-leaved can be obtained so readily, it seems surprising that so much inferior Parsley should be cultivated.—E. HOBDAY, *Ramsey Abbey*.

Dickson's First and Best and Sangster's No. 1 Peas.—We picked on June 14th 20 pecks of these Peas in fine condition. They were sown on January 14th on a border with a west aspect. Owing to the rows running across the border the soil was shaded sufficiently without mulching. Laxton, Alpha, and Kentish Invicta on a south border were ten days earlier but not such good croppers.—J. MILLER, *Clumber*.

Late-sown Parsley.—Where large quantities of Parsley are required at this season, it is a good plan to make a late sowing, say between the middle and end of July. A large proportion of all biennials sown after midsummer fail to flower the following season, and in the case of Parsley it is a decided advantage to have a part of the crop in this condition, as it permits the supply to be kept up without cutting too closely the young spring-sown crop.—E. HOBDAY, *Ramsey Abbey*.

Early Turnips.—Of Snowball, White Strap Leaf, Red American Stone, Early White Stone, and Yellow Altringham, sown early in March, the three first are producing good bulbs, and will be cleared off before the Early White Stone is anything like ready for pulling; it throws up too much foliage. For early Turnips I prefer Snowball and White Strap Leaf; when sown in succession they come in fine and tender all the season, and for late use a good breadth sown in August will keep up a supply during winter.—J. MILLER, *Clumber*.

Endive Running to Seed.—To avoid this at the present early season, the seed should be always sown in a dung frame, grown rapidly, and planted out on the top of a heap of leaf-mould or dung. Even now Endive should be sown in a frame, the seed germinated as quickly as possible, and planted out as soon as ready, on ground made moist with plenty of manure. Endive may be got up easily by simply sowing in heat and pricking out and planting when ready, as is done with early Celery. Thus treated, not 5 per cent. will run to seed.—CHEVALIER.

Beck's Dwarf Green Gem Bean.—This will be found most useful in both large and small gardens, as, unlike all other Broad Beans, it occupies but little room, about 15 inches between the rows being ample space for it, and, as it does not exceed 1 foot in height, it forms an excellent border crop. It is a remarkably free bearer and, when cooked, dark green in colour. A few rows of it on a south border will yield a large amount of produce. It is greatly superior to the Mazagan and the large coarse varieties usually grown for table use.—J. GROOM, *Henham Hall*.

SOCIETIES AND EXHIBITIONS.

THE YORKSHIRE FLOWER GALA.

It has been thought by some that flower shows have done their work, and that their general utilising influences and power to attract attention to the most beautiful products of Nature have worn out; but such would not have been the impression of any who had the good fortune to be present at the annual Yorkshire flower gala, which took place in the ancient cathedral city of York last week. The vast crowds that gathered from all parts of this large county in spite of the bad weather, which was most unusually windy and rainy for the season, afforded sufficient proof that an ever deepening interest in the successful growth of flowers and every other branch of horticulture continues to spread far and wide in all directions. The stream of visitors poured into the city by the various railways, which converge at York, scarcely ceased during the three days of the gala, and it was pleasing to notice that the crowd that passed along the suburb of Holgate to visit the matchless rock-garden in Messrs. Backhouse's nurseries was almost as great as that which made directly for the exhibition field at Bootham. The exhibition itself presented little more than the usual stereotyped selection of "specimen" plants. The Azaleas could not, for a moment, be compared with those of the London shows, but then it is getting late for them. A similar remark, however, applies to the Roses in pots, which ought to be in perfection in the middle of June; they were, however, not to be compared with such as we have seen exhibited by Messrs. Paul, Turner, Lane, and others in the Regent's Park. The show of cut Roses, however, was excellent, with some few exceptions; for instance, there was not a single first-rate bloom of Maréchal Niel or La France. Among the favourite kinds well represented may be named the following:—first and foremost, Madame Lacharme. This is certainly the largest and most perfectly beautiful of all the white Roses. Then there was Madame Villermoz, a fine cream-coloured Rose of somewhat similar form to Maréchal Niel. The next fine bloom calling for notice was one of Triomphe de Rennes, which is of a rich yellow, almost recalling Maréchal Niel both in colour and form. The blooms shown of Marquise de Mortemarte were exceedingly perfect and in good condition, as were also those of Louise Peyronny; Madame Bravy, a Rose of delicate pale yellow; Mdlle. Marguerite Jamain, an attractive Rose, of a bright lively cherry colour, and a novelty. The bedding system, whether right or wrong in principle, still holds firm possession in Yorkshire, if we may judge from the fine collections of zonal Pelargoniums which were exhibited. Looking at the contrasts displayed by many varieties of foliage on this occasion, the following ideas occurred to me as to utilising them in producing broad gardenesque effects. Take the following light-toned zonals, which exhibit modifications of yellow, straw-colour, and light pinky-brown,—say, for instance, Princess of Wales, Impératrice Eugénie, Crown Prince, Queen Victoria, Harrison Weir, and Duke of Edinburgh, and let them be picturesquely planted in close contiguity, the gradation of tone in regard to each other being, of course, carefully studied; then let an adjoining and strongly-contrasting mass be formed of the darker toned zonals, making use of such as Black Douglas, Marshal MacMahon, Bronze Perfection, Prince Arthur, &c. In this manner might be formed a miniature forest, as richly hued as the autumnal tints of American woods when in the full flush of their "Indian summer." These massive and magnificent effects might either be produced in the "landscape" arrangement, commencing close in front of low shrubberies and terminating irregularly against the well-dressed turf of sloping lawn in an irregularly-undulating outline; or this method might be applied in an analogous manner in geometrical arrangements. Some of those fine specimen plants which suggested the idea of obtaining grand effects at once in "bedding out" were trained in pyramidal form, by means of which great variety of effect might be obtained. The handsome silver cup offered by Mr. Bull, of Chelsea, was carried off by a Yorkshire competitor. In fact, with the exception of the fine display of plants sent from London by Mr. Williams, which was greatly admired, the excellent floral exhibition of the gala week, was almost entirely composed of plants furnished by growers from York, Beverley, Darlington, Bedale, and other local nurseries. The prizes offered for collections of alpine and hardy herbaceous plants were well responded to, and some remarkably pretty specimens were exhibited—amongst them was a plant of *Lewisia rediviva* in full bloom, the large crimson flowers of which attracted much attention. Among new varieties of well-known plants was a beautiful Conifer of the *Arbor-vitæ* class, with most strikingly variegated foliage. A large mass of a new *Coleus*, called Lord Wenlock, was shown by Mr. Mitchell, and is certainly one of the most brilliant varieties yet produced. A fine plant was shown of the new Pelargonium Queen Victoria, of which a coloured plate recently appeared in THE GARDEN. Among old favourite garden flowers several attractive new varieties were shown, so very superior in every respect to the old varieties still sent to all our flower markets that one cannot but be surprised at the perseverance with which the old and inferior varieties are still grown in such enormous quantities. I will only mention one instance—that of those popular favourites, the herbaceous Lobelias, three exquisite varieties of which were shown here, and I have not seen better in the metropolitan flower markets or any of the smaller London nurseries; these consisted of a profusely flowered kind of dazzling deep blue called Mazarine Gem; an exceedingly dwarf and compact variety of similar colour, which was as gorgeous as a mass of *Gentiana verna*; and also a large-flowered white variety touched with pure azure, called Miss Edgington. Space does not admit of my mentioning the display of fruit, which was, however, excellent.

ALEXANDRA PALACE ROSE SHOW.

JUNE 24TH.

THIS was, on the whole, a good exhibition, most of the growers, both amateur and professional, being well represented. Mr. W. Paul, Waltham Cross, furnished two stands of seedling Roses, and Mr. T. Laxton, of Stamford, also sent a stand of new seedling varieties. Mr. Paul's flowers were mostly under numbers, but H. P. Firebrand appears to be a good rich crimson variety, likely yet to make its mark as a good and distinct exhibition flower; Peach Blossom and the new Queen of Waltham were also represented by good blooms. Mr. Laxton had a seedling named Dr. Hogg, rather a small but richly-coloured purplish-crimson flower; Mrs. Laxton is a bright scarlet flower, similar in form to Marie Baumann; Emily Laxton is similar in form to Mr. Paul's Peach Blossom, but it is of a deeper rosy colour. Mr. Charles Turner sent two fine new seedling Roses, viz., Mrs. Baker, a smooth-petaled rosy-crimson flower of good substance, the older flowers being tinted with purple; and Oxonian, a distinct and remarkably full flower, the petals being closely imbricated, and of a rosy-crimson colour edged with lilac; it is a first-class flower, and was shown in excellent condition. The chief prizes in the nurserymen's class for seventy-two blooms were well contested, and most of the stands were in really excellent condition, the blooms being fresh and of that good substance which delights the eye of the enthusiastic rosarian. In the 1st prize group of seventy-two blooms, the following, amongst others, viz.:—Charles Bouillard, a fine full rosy-lilac flower; Duke of Connaught, rich velvety-crimson; Madame Thérèse Levet, a globular flower of the most delicate rosy tint imaginable; Madame Berard, a finely-formed Tea Rose in the way of the old favourite Gloire de Dijon; Sophie Coquerelle, a full lilac flower; Centifolia rosea, a fine bloom; John Hopper, Fisher Holmes, the Shah, Madame Lacharme, Emily Laxton and others equally good. In the nurserymen's class for forty-eight blooms, three trusses of each, some good stands were exhibited among which we noted flowers of Impératrice Eugénie, a nearly white variety flushed in the centre with flesh; Baroness Rothschild, in fine form, also Nardy Frères (rosy-purple), Alfred Colomb, and Exposition de Brie (crimson) were all well represented. Trusses of Madame Victor Verdier (rosy-salmon) and La Fontaine (rosy-purple) struck us as being far above the average in this collection, which also included richly-coloured flowers of Maréchal Niel, Charles Lefebvre, Souvenir d'un Ami, Oxonian (new), General Jacqueminot, Madame Berard, and others. In the nurserymen's class for twenty-four H. P. Roses only, three trusses of each variety, we noted some fine blooms, among which were Madame Vidot, La France, Marquise de Montemartre, Madame Lacharme, Madame Jamain, Baroness Rothschild, Centifolia rosea, and other light-coloured varieties; and, among the deep rosy and crimson kinds, the following were particularly effective:—Louis Van Houtte, François Michelin, Duc de Rohan, Dupuy Jamain, Horace Vernet, Fisher Holmes, Beauty of Waltham, Camille Bernardin, and Madame Victor Verdier. Three trusses of a distinct globular-shaped rosy-lilac variety, named Reine Victoria staged in the fourth prize group were unusually fresh and beautiful, and the second prize collection contained fine flowers of La France, Madame Eugène Verdier, François Michelin, Xavier Olibo, Etienne Levet (very fine), Madame Rothschild, and others. In the nurserymen's class 3, for twenty-four Hybrid Perpetual Roses, the first prize was awarded to a very effective stand of excellent blooms, including Néphétos (a delicate white Tea-scented variety, of fine form), Madame Hippolyte Jamain (a full delicate lilac-tinted flower), Charles Lefebvre (a deep velvety crimson), Madame Charles Wood (a fiery crimson), Capitaine Lamure (velvety purple), Etienne Levet, Exposition de Brie, and others equally good. In the nurserymen's class for twelve blooms, we noted some fine illustrations of the following, viz., Charles Lefebvre (a fine crimson flower, tipped with lilac-purple), Madame Hector Jacquin (a fine globe-shaped variety, of a clear satiny rose colour), Duchesse de Caylus (a fine full rosy-crimson flower), La France, Niphétos (a fine creamy yellow Tea-scented variety, very beautiful when seen in the bud), Captain Christy (a fine large rosy-lilac variety, with a deep rosy centre). In the class for eighteen trusses of English-raised varieties, some good flowers of the following kinds were staged, viz., Miss Ingram, a fine globular white flower suffused with pale rosy-lilac; John Hopper, a fine lilac-purple, with a crimson centre; Duke of Edinburgh, fiery crimson, with a rich velvety texture; John Stuart Mill, like Marie Baumann, but a shade lighter; Miss Hassard, rosy flesh, round, and full.

Tea Roses were rather poorly represented in amateurs' collections, but in some of the nurserymen's stands were finely-formed flowers of the following, viz., Mons. Furtado, a delicate sulphur, climbing Devoniensis, Cheshunt Hybrid, a fine lilac-purple kind, very delicately perfumed; President, a smooth petaled flower of a delicate rosy-salmon colour; Adam, soft rose; Souvenir d'un Ami, rose; and Maréchal Niel, bright yellow. Some of the flowers shown in this class were deeper in colour than in the single stands. Catherine Mermet, a fine rosy-salmon, Pauline Labronté, a bright satin-like rose, with a bright salmon centre; Solfaterre, a delicate sulphur-tinted Noisette; Rubens, a wax-like creamy-white flower; Perle de Lyon, a fine golden-tinted variety, with a deep salmon centre; Madame Capucine, a bright rosy-salmon, very distinct; Gloire de Bordeaux, a fine full rosy-lilac flower; and Belle Lyonnaise and Madame Villermoz, both good. Eight stands of Tea Roses were staged by amateur growers, and six by nurserymen, those of the last-named being by far the best in point of quality.

In the amateurs' class, for forty-eight cut blooms, some fine and remarkably even stands were contributed. Among blooms in the first prize stand were excellent examples of John Hopper, Madame Rady, Alfred

Colomb, Louis Van Houtte, a rich velvety Rose, of a purplish-crimson colour; Baron Adolphe de Rothschild, a fiery-scarlet, the edges of the petals curiously crisped; Victor Verdier, and Centifolia rosea, a fine bloom; Beauty of Waltham, Edouard Morren, a full and bright rosy-salmon flower; Madame Eugène Verdier, Duchesse de Caylus, and others. In the second group were good flowers of Céline Forestier, Marquise de Castellane, Madame Rivers (a well-known old favourite), Madame Margottin (yellow Tea), John Hopper, Caroline de Sansal, and other well-known kinds. In the amateur class for thirty-six cut blooms, the stands were in many cases very poor. Three of the exhibitors, however, contributed very effective and well-arranged stands. In the first prize groups, we noted good blooms of Pierre Notting, a full purplish variety; Marie Rady; Etienne Levet; Madame Victor Verdier, Ferdinand de Lesseps, a bright rosy-crimson variety, very full; Centifolia rosea, and others. In the amateurs' class for twenty-four cut Roses, seventeen stands were staged, some of them containing blooms of very fine quality. Among the best were Madlle. Marie Rady, a fine full flower of the Marie Baumann type, but of a more decided purplish-crimson colour; Centifolia rosea, a fine rosy-lilac, one of the oldest, and still one of the best; Xavier Olibo, a deep velvety-crimson; La France; Duchesse de Caylus, a fine full crimson flower, similar in form to Madame Baumann, but brighter; General Jacqueminot, brilliant crimson-scarlet; Dupuy Jamain, a fine smooth-petaled variety of a bright purplish-crimson colour; Etienne Levet, a full rosy-lilac; Souvenir de la Malmaison (Tea), bluish; Paul Verdier, rich crimson; Annie Laxton, a high-coloured satiny variety of a distinct rosy-colour; Madame Norman, white, with flesh-coloured centre; Abel Grand, a fine full rosy-lilac flower; Dr. Andry, rich velvety-crimson; Comte de Paris, a full rosy-crimson variety, with stout waxy foliage; the Shah, a small bright velvety-scarlet rose; Madame Alice, Dureau is a fine full flower, the colour being a delicate satin-like rose, and Lady Suffield is a good flower of the Marie Baumann type. Some very fine single stands (twelve trusses) of flowers were staged of Duke of Edinburgh, a fine new crimson-tinted Rose of good form, with smooth velvety petals, and in every respect a first-class dark kind. Some very fair stands of Maréchal Niel were staged, but in most cases the blooms lacked freshness, and in more than one case they were deficient in colour; Marie Baumann, a fine, full, crimson-lilac-tinted variety, was shown in good condition by half a dozen different growers, some of the stands containing blooms remarkably fresh and of good substance. This is, in every respect, a first-class Rose, being fine in form and rich in colour; some of the freshest of its flowers had a brilliant fiery glow, while the older blooms were delicately tinted with lilac. La France, the best light Rose of its class was represented in some half a dozen good stands. The new white Hybrid Perpetual Rose Madame Lacharme was well shown by four exhibitors. Its flowers are nearly perfect in shape, and white in colour, with just a flush of flesh or rosy-salmon in the centre. Two good stands of Princess Beatrice were staged, but some of the flowers wanted freshness. The soft rosy Baronne de Rothschild was represented in two or three good stands, some of the flowers being 6 inches across, and of good form and substance. There were two or three very fine stands of Edouard Morren, now a well-known exhibition variety, globular in form, and rosy-lilac in colour, with a rosy-crimson centre. Alfred Colomb was represented in four excellent stands. This is a finely-formed and well-known exhibition Rose, of a fiery-crimson colour, round and full. Several subjects of a miscellaneous description were contributed, but for the names of those who showed them, as well as for those of successful competitors in the different classes of Roses, we must refer to the prize list (see p. xvii. of Advertisements).

Pansy Propagation.—Allow us to inform "Enquirer" (see p. 492) that cuttings of bedding Pansies and Violas are better than seedlings, inasmuch as the latter do not come true to colour. Cuttings ought to be put in in a shady border or cold frame in September. The following may be depended on for early spring flowering, viz.:—Yellows: Viola Golden Gem and Griewel, and Pansy Golden Bedder; blue: Pansy Blue King; plum-purple: Viola Alpha and The Tory; white: Viola White Perfection, Dickson's White Bedder, and Dean's White Swan.—Dicksons & Co., 1, Waterloo Place, Edinburgh.

—Cuttings are better than seeds. For very early spring blooming, they should be put in now. They root freely in a somewhat sandy soil, under a shaded frame or hand-glass. A quicker way of propagating them is to divide the old plants so as to leave a small root to each shoot, and to lay them in the ground in some shaded corner. Dickson's Blue Bonnet and Blue King, White Queen, Regina, Golden Bedder, and Sunbeam, are all excellent kinds for bedding. Many of the Violas are quite as beautiful and useful as Pansies; and among the best I have tried are the following:—Blues, Eyebright and mutilata; yellow, Golden Gem and Canary; whites, White Bedder and Snowflake. Violas may be increased in the same way as Pansies. For summer and autumn blooming, the cuttings need not be put in until the beginning of October.—J. Muir.

OBITUARY.

WE have to record, with much regret, the death of Mr. William Rollisson, the head of the well-known nursery firm of that name at Tooting, on Friday, the 18th inst., in the seventy-third year of his age. Independently of his professional reputation, which was deservedly high, Mr. Rollisson's geniality of disposition and straightforwardness of character endeared him to a host of private friends, who will not soon forget his loss.
